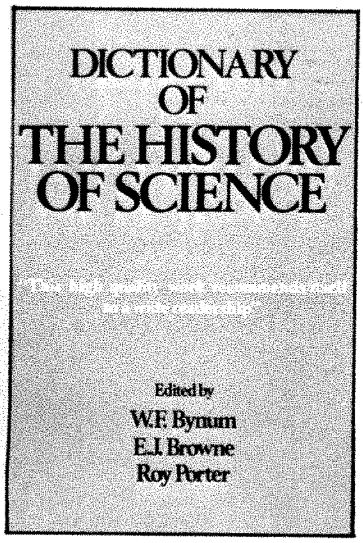
STAINING CELLS TO STUDY DEVELOPMENT

4011



Special offer to subscribers to Nature – Save £3.50 off published price!

Is this the missing link?

Is there a gap in your bookcase? Until now, there hasn't been a dictionary devoted exclusively to the history of scientific ideas. And however you are involved in today's scientific world, you will agree that your present work and scientific attitudes are inevitably influenced by and built on those from the past.

Science and its key doctrines – from quantum theory to genetics – are central to the modern world; yet daily it changes and develops, becomes more technical and diverse. What is needed is a reference book that enables you not only to master the past but also to keep you in touch with the theories underlying the most recent scientific and technological developments.

The Dictionary of the History of Science fills the gap.

Authoritative
It is the work of three editors: W.F. Bynum, E.J. Browne and Roy Porter; of ten subject editors – including Michael Hoskin, Richard Burkhardt, William Brock, Steven Shapin, Roger Smith, Eric Aiton, Roy Bhaskar, John Heilbron – and over 90 contributors, all authorities in their field. It explains the core features of Western science and their development. 700 entries, alphabetically arranged, cover such fields as astronomy, biology, chemistry and earth sciences, the historiography, philosophy and sociology of science; human sciences, mathematics, medicine and physics.

Substantial concepts such as Evolution and Light are given generous entries, while more specialized sub-areas like Neo-Darwinism and Light Velocity are allocated smaller amounts of space. All are cross-referenced back and forth.

Comprehensive
Although the Dictionary is principally concerned with the Western scientific tradition of the last 500 years, it touches, too, on the central scientific ideas of classical and medieval times, and of other cultures. In addition, it features such topics as the development of technology and clinical medicine, and of important scientific instruments like the astrolabe and the thermometer.

Our understanding of the processes of scientific discovery and change is often controversial. But however you view them, it is important that you have easy access to all the ideas you are building on today, in the most scholarly, up-to-date and comprehensive detail.

If you are searching for the missing link, the Dictionary of the History of Science is your natural selection. At this special price to subscribers to Nature, it must be!

Price: £14 (Published price: £17.50)
496 pages: **234** × **156** mm.: **700** entries: bibliographies: biographical index: ISBN 0 333 29316 9

Please supply . . . . . . copy/copies of the Dictionary of the History of Science (ISBN 0 333 29316 9) at the special Nature subscriber price of £14. I understand that I will not be charged for postage and packing. This special offer closes on March 30th 1982.

•How Britain runs its Science
•How the US runs its Science

These two new *Nature* wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or $7.95 each from *Nature's* offices in London, Basingstoke and New York.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.*

Introducing

THE CENTRIFUGAL FORCE MACHINE

To 110,000 x g (25,000 RPM)

Let's face it. A machine that is used to produce force shouldn't communicate only in terms of RPM. It's somewhat like a car without a speedometer or odometer.

That's why we taught the new MICRO-25 to talk RCF. You simply key in the g-force desired, rotor number, acceleration and deceleration characteristics, run time and temperature. The instrument does the rest. You can even specify the force at any given point in your sample tube. And the continuously displayed G × minute parameter gives you a direct readout of the entire centrifugal field applied during the run, enabling straightforward experimental replication.

The MICRO-25's computer and its many operational and computational features are just part of the story. There are significant mechanical innovations as well. Like a speed control system with ± 5 RPM accuracy. And an infrared temperature detector that enables *rotor* temperature control to ± 0.5°C.

If you're considering the purchase of a high speed centrifuge, consider a high force machine instead. Send for complete information.

■ Up to 50 stored programs ■ Multiple segment program capability for stepped centrifugation ■ Continuous display of set and actual run conditions ■ Superior speed control, ± 5 rpm ■ Rotor recognition ■ Infrared rotor temperature detector, ± 0.5°C control ■ Safety cover interlock system ■ Automatic overspeed protection ■ Delayed start feature ■ Absolute containment

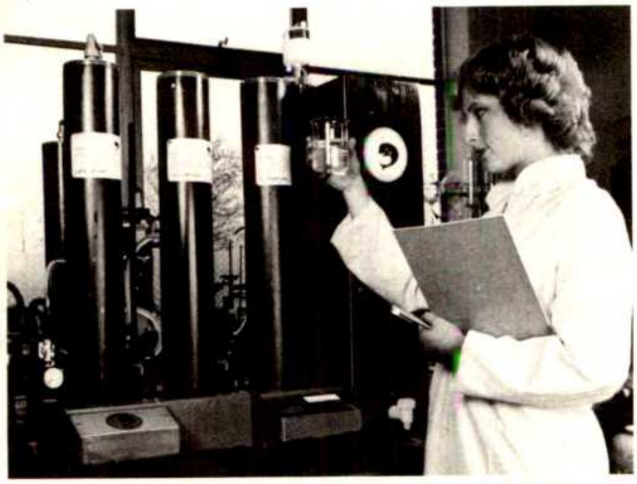
BRITISH MADE

ULTRA PURE WATER WITHIN YOUR GRASP

Analytical grade water at less than 4.0 pence per litre, in any volume and with the minimum of maintenance. These are a few of the advantages of Elga's extended range of Laboratory Reverse Osmosis units.

Designed to meet the growing demand for organically pure, colloid-free water in HPLC tissue culture etc. LabRO and Spectrum RO are cost-efficient answers to a common laboratory problem.

LabRO is a self-contained unit for either bench mounting or free standing and is the latest product of Elga's reverse osmosis expertise. A LabRO unit can produce up to 1,000 litres per day.



Spectrum RO is an addition to the established Spectrum deioniser range and is ideal for the production of smaller volumes.
There is more, much more, that you should know about these products, so contact Elga today for full information.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.*

Miles-Made
Peroxidase Conjugates

High titers...for high dilutions.

Miles offers a broad selection of peroxidase conjugated antisera, each tested for satisfactory immunoassay performance. Some popular products include:

Peroxidase Conjugated	Host	Code No.
Anti-Human IgA (α)	Goat	61-131
Anti-Human IgE (ε)	Goat	61-133
Anti-Human IgG	Goat	61-230
Anti-Human IgM (μ)	Goat	61-132
Anti-Goat IgG	Rabbit	61-201
Anti-Mouse IgG	Rabbit	61-204
Anti-Rabbit IgG	Goat	61-202

For a complete listing of Miles peroxidase conjugated antisera and lectins, call or write:

Miles-Made
Alkaline Phosphatase Conjugates

The Miles label, a quality standard in biochemicals and immunologicals, guarantees consistent quality in antisera.

We offer a wide range of antisera conjugated with labeling-grade alkaline phosphatase that is highly suitable for use in immunoassay procedures.

Alkaline Phosphatase Conjugates

Antigen	Host	Code Number
Goat IgG	Rabbit	61-276
Guinea Pig IgG	Rabbit	61-279
Human IgA (α)	Goat	61-272
Human IgG	Goat	61-270
Human IgM (μ)	Goat	61-271
Mouse IgG	Rabbit	61-278
Rabbit IgG	Goat	61-275
Rat IgG	Rabbit	61-277

Cover

A complete carrot plant regenerated from roots containing a region of the virulence plasmid of *Agrobacterium rhizogenes*, causative agent for hairy root disease. This Ri plasmid joins the Ti plasmid (causing crown gall disease) as a possible vector for genetic engineering in plants. (See page **432**.)

Grain alignment in the galactic magnetic field (a review) — P E Johnson — 371

ARTICLES

Ultrasonic borehole televiewer investigation of oceanic crustal layer 2A, Costa Rica Rift — M D Zoback & R N Anderson — 375
Resolving the functions of overlapping viral genes by site-specific mutagenesis at a mRNA splice site — C Montell, E F Fisher, M H Caruthers & A J Berk — 380
Unusual physical organization of the *Halobacterium* genome — C Sapienza & W F Doolittle — 384

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

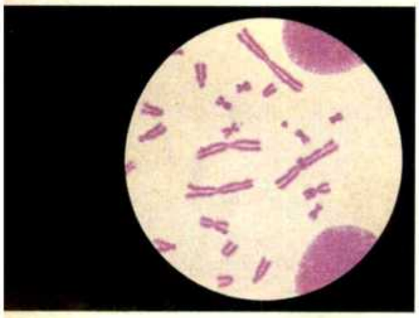
Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

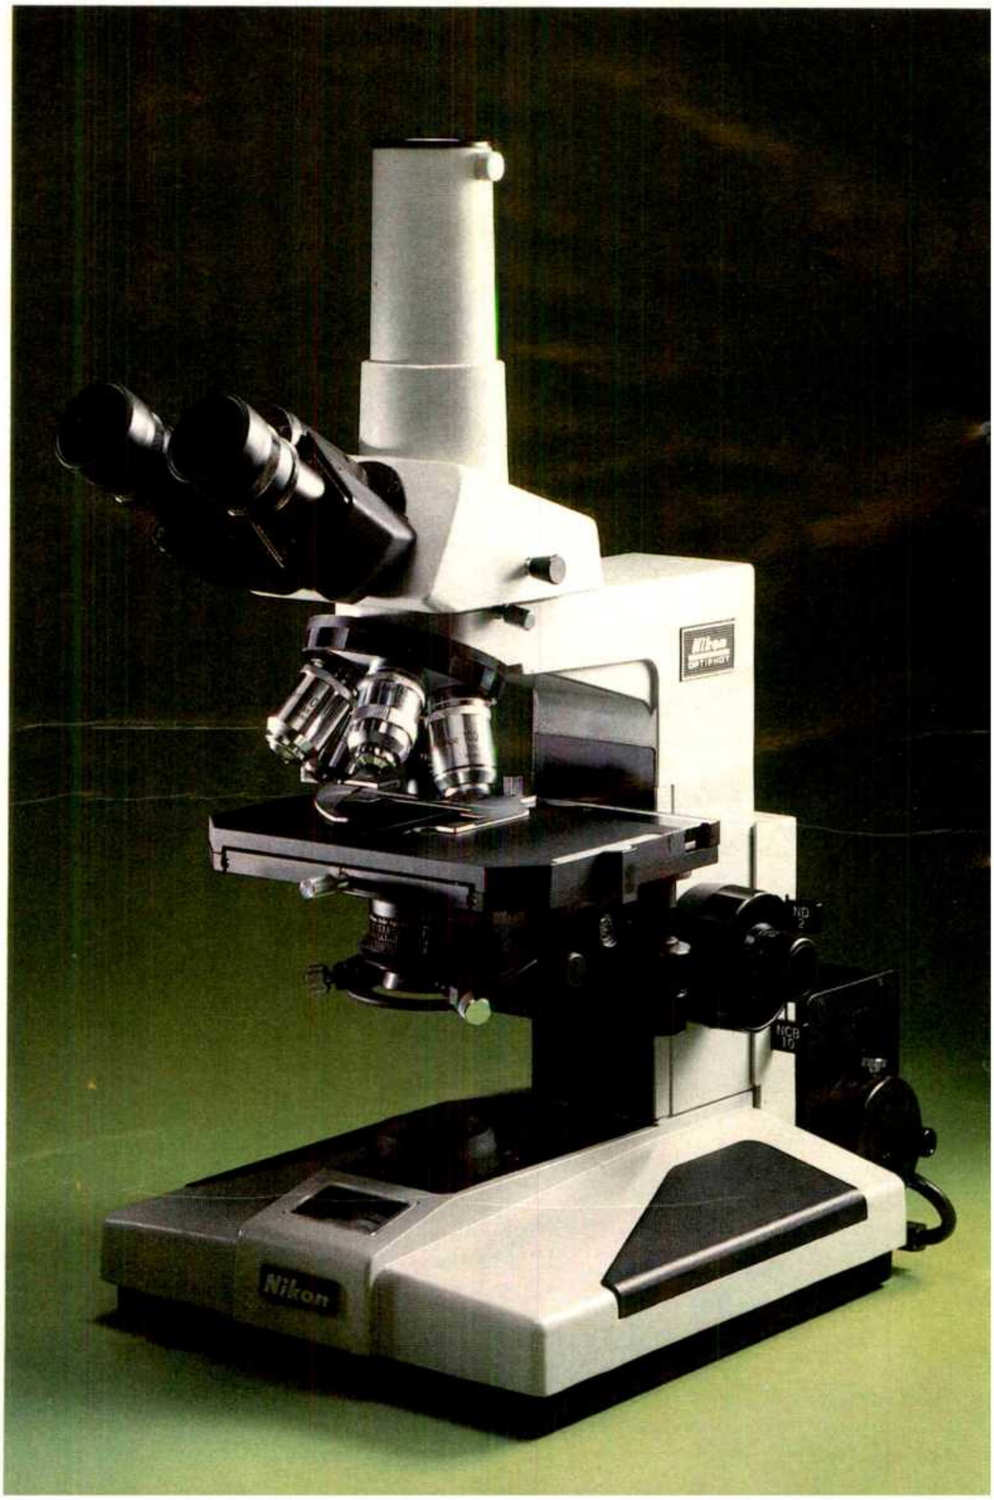
Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.*

NIKON VISIONS



NIKON HIGH-PERFORMANCE CF OPTICS. POSSIBLY THE FINEST EVER AVAILABLE.

CF Plan Apochromat 100x (Oil) N.A. 1.35 Mouse chromosome, gimsa stain



INSTRUMENTATION
Nikon Optiphot microscope with CF objectives.

SIGNIFICANCE
Nikon's revolutionary CF optics virtually eliminate chromatic aberration. Within this series, several high-performance objectives significantly extend observation powers.

SPECIFICS
While all Nikon CF objectives provide a dramatic improvement in resolution, color rendition and contrast over the old compensation system, the following lenses are exceptional. The unique CF 2x plan apochromat has excellent image flatness for low power photography. The CF 40x plan apochromat, N.A. 0.95, dry, produces exceptionally bright, high-contrast images. Nikon's CF 100x NCG plan apochromat is designed to work without a cover glass. Its sharpness must be seen to be believed.

These remarkable optics are matched to a microscope body and illumination system equal to their performance — the Nikon Optiphot. This totally new design is extremely stable. A standard 50-watt halogen Koehler illumination system covers all magnifications without need for adjustment, and the full range of Nikon accessories is available to match any assignment.

Extend *your* vision. Write:
NIPPON KOGAKU K.K.,
Fuji Bldg., 2-3, Marunouchi
3-chome, Chiyoda-ku, Tokyo
100, Japan.

Macmillan Journals Ltd.,
Brunel Road, Basingstoke,
Hants RG21 2XS, UK

•How Britain runs its Science
•How the US runs its Science

These two new *Nature* wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or $7.95 each from *Nature's* offices in London, Basingstoke and New York.

SAFE

n the knowledge of Barr & Stroud technology at work

A commonplace scene on a busy road, but safer if Barr & troud fibre optic traffic signs were installed.

Our signs allow virtually no misleading phantom images ven in the most difficult conditions.

We are a leading light in the fibre optics field, where our xperience spans a wide spectrum of equipment, systems nd applications—in computers, process control, medicine, colour detection, automatic inspection, as well as traffic signs.

Barr & Stroud's leadership and innovative skills in today's technologies are at the service of science and industry.

We have proved it in fibre optics; we have proved it in other areas. Because of our serious commitment to research and development, engineers and designers everywhere can rely on our expertise to solve their most complex problems.

Barr & Stroud
make fibre optics work

NET-429A 250µCi 1mCi 5mCi in dry ice
dGTP, [8, 5′-^{3}H]- 25-50Ci/mmol
NET-448A 1mCi 5mCi in dry ice

Also available in standard ethanol:water packaging by deleting the A from the ordering number.

Circle No.39 on Reader Enquiry Card.

ω-3 Polyunsaturated Fatty Acids

For studies of the metabolic pathways and biological actions of these acids

Linolenic acid, 9, 12, 15-[1-^{14}C]-
40-60mCi/mmol Ethanol under argon, in dry ice
NEC-779 50µCi 250µCi
Docosahexaenoic acid, 4, 7, 10, 13, 16, 19-[^{14}C(U)]-
>100mCi/mmol Ethanol under argon, in dry ice
NEC-784 5µCi 10µCi
Eicosapentaenoic acid, 5, 8, 11, 14, 17-[1-^{14}C]-
40-60mCi/mmol Ethanol under argon, in dry ice
NEC-772 10µCi 50µCi
Eicosapentaenoic acid, 5, 8, 11, 14, 17-[^{14}C(U)]-
50-100mCi/mmol Ethanol under argon, in dry ice
NEC-754 5µCi 10µCi

Circle No.42 on Reader Enquiry Card.

Calmodulin [^{125}I]

Stable. Produced by Bolton-Hunter Reagent conjugation to bovine brain calmodulin
Tested for antibody binding
Calmodulin,[^{125}I]-
50-150µCi/µg
0.05M phosphate buffer, pH 7.4, 0.1M NaCl
0.1% gelatin, 0.05% sodium azide
NEX-172 5µCi 10µCi
Also available . . . Calmodulin,[^{125}I]- RIA Kit

Circle No.43 on Reader Enquiry Card.

Iodocyanopindolol [^{125}I]

Specific to β_1 and β_2 adrenergic receptors
Higher affinity (K_D~27-40pmol) and specificity than iodohydroxybenzylpindolol
Carrier-free~5400µCi/µg
Iodocyanopindolol,[^{125}I]-
2200Ci/mmol
n-Propanol:water:phenol (50:50:1.2), in dry ice
NEX-174 100µCi 500µCi 1mCi

Circle No.44 on Reader Enquiry Card.

FSH, LH [^{125}I]

Follicle Stimulating Hormone,[^{125}I]-
50-100µCi/µg
Lyophilized from sodium phosphate buffer, pH 7.4, containing BSA and a proteolytic enzyme inhibitor
NEX-173 10µCi 25µCi 100µCi
Luteinizing Hormone,[^{125}I]-
50-100µCi/µg
Lyophilized from sodium phosphate buffer, pH 7.4, containing BSA and a proteolytic enzyme inhibitor
NEX-170 10µCi 25µCi 100µCi

Circle No.45 on Reader Enquiry Card.

Not for use in humans or clinical diagnosis.

•How Britain runs its Science
•How the US runs its Science

These two new *Nature* wallcharts are now available.

The 2 x 3 ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or $7.95 each from *Nature's* offices in London, Basingstoke and New York.

Confidence, IT COMES FROM QUALITY.

Reproducible high resolution is the result of quality chemicals and equipment. Quality of design and synthesis has been incorporated into isoelectric focusing products from Pharmacia Fine Chemicals, giving you confidence in performance every time.

Some of the new quality design ideas used in construction are: **movable electrodes** (so you can use any gel size you need), **high efficiency aluminum cooling plate** (for faster runs at higher voltages), **larger cooling plate size** (to increase sample number or for preparative work), and our latest response to your requests—a **cooling plate with grid markings** (for fast and accurate set-up).

Our unique synthesis procedures for Pharmalyte® carrier ampholyte and Agarose IEF give you quality chemicals on whose consistent performance you can rely. Each Pharmalyte interval yields a stable and linear pH gradient in either polyacrylamide or agarose. The low and even conductivity of Pharmalyte allows you to focus faster at high voltages confidently—even at 3000V with the Electrophoresis Constant Power Supply ECPS 3000/150.

Agarose IEF is a highly purified, balanced charge agarose making it the matrix of choice for reliable focusing of proteins. Agarose IEF is easy and reliable to use since there is no worry about electroendosmotic effects, various polymerization problems, toxic chemicals or lengthy staining and destaining times.

The use of quality isoelectric focusing equipment and chemicals from Pharmacia Fine Chemicals assures you high resolution IEF results without risking your sample or equipment.

Pharmalyte: Consistent gradients and low, even conductivity continues to be the hallmark of ready-to-use Pharmalyte carrier ampholytes.

ISOELECTRIC FOCUSING EQUIPMENT AND SUPPLIES QUALITY HAS MADE Confidence A REALITY.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.*

Nature announces the first wall chart showing how the U.S. runs its science

...shows who makes U.S. science decisions, who gets the money, and how it's spent

If you're involved in making decisions about science, or if you're looking for your share of science funding, you need Nature's new 1981 guide to how the nation spends its science dollars and who controls that money.

Compiled by Nature from literally hundreds of sources, the wall chart offers data on actual dollars spent on science by government agencies, industry, foundations, universities, research and medical centers. The chart lists key U.S. government policy makers, with their addresses and phone numbers.

Most significantly, the chart shows the interlocking relationships within the science, engineering, and medical establishments.

Designed as a fold-out that you can carry to meetings, or for hanging as a 2 x 3 ft. wall poster for permanent reference, the chart enables you to answer questions that might otherwise take weeks of research to dig out. Compact, color-keyed, and handy, it will be an enormous aid to you and your colleagues. We strongly urge you to order sufficient copies to cover the needs of your entire staff or department.

"How the U.S. Runs Its Science"

—another authoritative publication from Nature, for more than 100 years, the world's most respected source of science data.

Reagan's mistake on Soviet sanctions

The US Administration, seeking to punish the Soviet Union for what is happening in Poland by suspending an exchange agreement, has revealed its ignorance of what science is for.

Towards the end of the Napoleonic wars, Sir Humphry Davy went on a journey on the European mainland untrammelled by the circumstance that Britain was literally at war with France (and that most other European states were at war with at least one other) The journey, frequently described as an illustration of how even then the international interests of science took precedence over international politics, is made still more pointed by the knowledge that Davy was combining business with pleasure — his honeymoon Personal travel and national hostilities were, it seems, independent of each other Now all that has changed President Ronald Reagan's suspension last week of the exchange agreement between the United States and the Soviet Union, part of his programme of sanctions against the Soviet Union in response to the supposed Soviet support of martial law in Poland, will effectively put latter-day Davys in their place It is also a stupid and a dangerous move It should be quietly abandoned

Programmes of economic and cultural sanctions have been frequently tested in the years since the Second World War, and have as frequently been found wanting The best thing to be said about them is that they are less damaging than outright warfare They are also, usually, ineffectual, as President Carter found after Afghanistan On this occasion, the difference of opinion between some Western European governments and the United States on the wisdom of sanctions as a means of interdiction will further undermine what President Reagan can hope to achieve — which by all accounts (see page 3) is not in any case very much It is however clear that neither he nor his advisers appreciate the enormity of including within a set of sanctions the suspension of a longstanding programme for the exchange of academic scientists between one country and another

This is why Open warfare is a means by which one nation state can legitimately (*pace* the pacifists) enforce its will on another Even nations that unfashionably declare war on others usually express their hope that in due course all will again be sweetness and light Programmes of sanctions, damage-limiting though they may be, also anticipate the earlier return of normalcy So sanctions should be designed to maximize the short-term damage done but to create as few impediments as possible for the hopefully happy years ahead Denying the Soviet Union the right to buy pipe-laying machines in Texas is unambiguously in the former category, suspending the exchange agreements unfortunately in the latter

That there should have to be formal schemes for enabling scientists from one country to work, if they wish, in laboratories in another is, of course, in itself a mark of failure If Dr X should wish to work in Dr Y's laboratory and Dr Y should be agreeable, and if one or other should be able to find the necessary funds, why should governments be involved? People like Mr Frank Carlucci, Deputy Secretary at the Pentagon, think they know why not if Dr X is a Soviet citizen, he will be part of a "highly orchestrated, centrally directed" effort to pick the brains of unsuspecting American scientists Mr Carlucci is naturally right to say that Soviet participants in the bilateral exchange agreement benefit from their visits to the United States, and are afterwards potentially more useful as applied scientists, sometimes in military programmes But is there any evidence that their American hosts, the Dr Ys of this world, are entirely without benefit? If so, the exchange programme has been maladministered — visitors have been foisted on unwilling hosts If not, Mr Carlucci should embark on what would be called an evaluation of the benefits and disbenefits of the exchange programme He would come to two conclusions — first, that the total benefit from mutually sought exchanges for the research enterprise is greater than the sum of the individual benefits and, second, that his government's proper course of action, as a signatory of the Helsinki accords, is to insist that the then agreement, at least in principle, that people should be more or less free to move to where their inclinations take them, should be honoured

That, unfortunately, will seem too abstract a course to the Reagans and Carluccis of this world The Soviets *are* benefiting, and must be prevented from doing so, they will say And we know that Helsinki doesn't work, don't we? That, of course is true, even if the statement of the truth comes oddly from the inheritors of those who negotiated the agreement But the reasons why Helsinki has failed in respect of scientific exchanges need more careful consideration The objective now should be to restore some semblance of the *laissez-faire* of Humphry Davy's time The only way of doing that is to shift responsibility for the administration of exchanges from the State Department (and the Pentagon) to some convenient halfway house such as the National Academy of Sciences That stratagem has been adopted elsewhere, even in backward Britain Perhaps the time has come when the National Academy of Sciences in Washington should insist that no other body, not even the State Department, can do what is required If necessary, it should be prepared to raise the funds required privately, from the foundations and from industry

More change now due

Reform of the British research council system is overdue. Does the government have time?

The British government has mostly done the decent thing in its dealings with the publicly-supported research councils Broadly speaking, their budgets for the financial year beginning on 1 April are unchanged (see page 4) So the Prime Minister will be able to tell the British electorate at the next general election, some time before 3 May 1984, that she has "protected" publicly-supported civil science from damaging economies On present form, the government may have very little else to boast about at the end of what is almost certainly its last full financial year in office But this is not a vote-catching issue Thus the government's generosity towards the research councils — a curious description of a recipe for continued stagnation, but appropriate in the circumstances — must be taken as deliberate Will it therefore, in the remainder of its time in office, put in hand the structural reforms of the mechanisms for supporting the five research councils that are now long overdue?

The research councils are inevitably a mixed bunch But even those with responsibilities for fostering basic research in fields such as medicine or agriculture are important sources of support for university research The Science and Engineering Research

0028-0836/82/010001-02$01 00

Council, on the other hand, although enjoined to support academic research, has for the past decade been flirting with ways of making university research more directly relevant to British industry. On the grounds that all of the councils have a finger in the university pie, their funds are channelled through the Department of Education and Science, but the total sum available each year has for the past decade been divided between the various councils on the recommendation of the Advisory Board for the Research Councils. Even when this mechanism was established, in the wake of the Rothschild reorganization in 1971, it was feared that the board, on which the executive officers of the research councils are necessarily influential, would become an arid device for sharing out funds in such a way as not to give too much offence. So it has turned out.

The advisory board is thus an obvious candidate for change. But how? There is much to be said for the recipe offered last November by the House of Lords Select Committee on Science and Technology — appoint a full-time chairman, give him (or her) a small staff and require the board to comment on the policy questions that now go largely by default. Under such an arrangement, the chairman of the board would become what the Department of Education and Science now conspicuously lacks — a chief scientist of a kind. These proposals have the advantage that they could be put into effect without much trouble. They would also be improvements. The government should listen to what the House of Lords has said, and quickly.

There are, however, snags. The reform of the Advisory Board for the Research Councils along the lines suggested by the House of Lords committee would leave untouched the habitual secrecy of advisory bodies working for British government departments. The theory is simple, advisory bodies exist to give advice which ministers may, at their pleasure, decline. And, the argument goes, it would be unseemly, cramping and politically irksome if the rejection by a minister of an advisory committee's advice were publicly advertised. But this is precisely what has happened with this year's advice on the research council budgets. The decision that the budget of the Social Science Research Council should be reduced by £1.1 million (just over 5 per cent) was taken by Sir Keith Joseph, the Secretary of State for Education and Science, in flat contradiction of the recommendation of the Advisory Board for the Research Councils. No explanation has been given, so that there is no way of telling whether the minister's fiat reflects the fashionable animus against the social sciences or whether there were — as there might well have been — more substantial grounds for his decision. Whatever the truth, the minister is likely to be more seriously damaged by the gossip that will now flourish than he would have been by an open discussion of his reasons. Secrecy, it seems, hurts even those whom it is intended to protect.

The case of the Social Science Research Council illustrates another weakness of the present system. The council was set up nearly twenty years ago to foster academic research in the social sciences. Throughout that period, it has struggled hard to establish academic centres of excellence in the face of open hostility from its enemies and, more disarming, the wayward kookiness of some of its friends. On the grounds of youth, it was exempted from Lord Rothschild's recommendation in 1971 that government departments should pay for the cost of applied research supported by the research councils. Since then, the Social Science Research Council has been complaining that government departments are too fond of stealing its clothes by commissioning basic research from their own resources. Now, ironically, there is to be another inquiry by Lord Rothschild into the application of the customer–contractor principle in this field, one result may be to reconcile the advisory board with its minister.

What will remain undecided are the questions that the advisory board should have had the wit to take up several years ago — is a research council the best mechanism for fostering the social sciences? what criteria of excellence make sense? and what, in any case, is to be made of the peculiarly British sneer that what are called the social sciences are not science? It is easy to understand why the advisory board would have shrunk from such an investigation, if the precedent were established that the constitution of the newest research council might be questioned, who could then ensure that the well-established councils were free from scrutiny? The advisory board, in other words, is undermined by backscratching which is then strengthened by the convention of secrecy.

The habit of secrecy is not merely damaging to all those concerned but also inappropriate. Over the years, the research councils have (to their credit) established a remarkable sense of trust with their customers in the universities. In Britain as elsewhere, the peer review of research proposals has created a sense that substantial parts of their budgets are spent by the scientific community, not by career officials. Some of the councils have also developed a knack of putting controversial ideas into circulation before they are finally decided. But the questions that the advisory board should be tackling — the place of social science, the health (or sickness) of the dual support system, the success (or otherwise) of the University Grants Committee's designated courses in engineering education and so on — are also questions that cannot be settled convincingly by a small group of people, however appointed.

The lessons for the government are clear. The advisory board should be strengthened along the lines suggested by the House of Lords and, in the process, the dominant influence of the research councils should be deliberately weakened but not abolished. Then, some device must be found for making the advisory board a more public body, able at least to advertise the issues on its agenda and ideally compelled to publish not less than once a year a reasoned account of what it has been doing. There is no substantial danger that in the process the British Constitution would be undermined or the freedom of ministers compromised. On the contrary, ministers would be less at risk than at present of having to make up their minds without the benefit of even half-baked advice.

Not president perpetual

Dr Philip Handler, who died last week served the US National Academy of Sciences well.

Being President of the United States is a relatively simple job, power and patronage help to bring to heel unwilling cabinet colleagues and even members of the Congress. Presidents of the National Academy of Sciences in Washington enjoy no such benefits. Even though elected, they must continually reassert their authority among their electors, many of whom declare that they could do the job just as well if only they chose to spend their time in such a demeaning way. One measure of Dr Philip Handler's achievement in this office is that during his twelve-year stint at the academy, which ended last June, he was twice re-elected.

A large part of the explanation is that he was an articulate man, he could make fine speeches but also talk his way out of trouble. He was also courageous. He fought the extremists among the environmentalists when many others thought it prudent to keep their heads down. He fought Congress on several occasions, not only about the scale of support for research but over occasional threats of interference. Handler's early years at the academy saw the rapid growth of its secular activity — producing reports on topical issues, sometimes important and sometimes trivial — whereafter he had to fight the committees for the right to ensure that their reports were properly reviewed before publication. Not all his battles were successes. The campaign to finance the purchase of Einstein's statue now in the academy's front garden might have been successful if the statue had been better.

Inevitably, continual battles take a toll. Handler, always an iconoclast, occasionally seemed to be oversensitive to criticism. Latterly, he was concerned to know what he would do on leaving the academy and, more recently, was embrittled by his largely secret knowledge of his mortal illness. He will, however, be remembered well, not merely for his wit and eloquence but for having rescued the academy from its earlier spells of idiosyncratic and then indolent leadership — and for ensuring that it is no longer simply an academy.

Anxiety about Reagan's sanctions

Two views on the wisdom of suspension

Washington

President Reagan's announcement last week that the United States is suspending its scientific exchanges with the Soviet Union, as part of a package of reprisals aimed at chastising the Soviet Union for its support of the military clampdown in Poland, has provoked concern in the scientific community that the move indicates an increasing willingness to use science for explicit political purposes.

The immediate effect of the President's decision will be to suspend the scientific exchange agreement signed by President Richard Nixon and Soviet President Leonid Brezhnev in 1972. Furthermore, Mr Reagan announced that unless the situation in Poland changes the agreement will not be renewed when it runs out in July.

Similarly, agreements for cooperation in energy and space research will not, at present, be renegotiated when they run out in May. And a number of other agreements which include scientific components are also being suspended and reassessed.

To a large extent, however, Mr Reagan's decision to suspend scientific exchanges is viewed as more symbolic than substantive. In the case of high-technology trade, an area announced for suspension, even the US Department of Commerce accepts that the Soviet Union is little more than a "marginal market" for sophisticated equipment, accounting for less than one per cent of the US electronics industry's annual sales of $200,000 million, and that the Soviets may well be able to meet their needs from other sources.

Officials at the National Science Foundation, which is responsible for nine of the twelve working groups still operating under the terms of the 1972 agreement, argue that as a result of deliberate efforts over the past few years to eliminate exchanges involving a marked imbalance of benefits, those still in effect provide scientific benefit to both sides.

Many — although not all — US scientists fear that if even these exchanges are now halted, the effect could be counter-productive. Not only would it close off an important channel of communication between two intellectual communities, but it would provide a useful propaganda weapon for use against those attempting to separate politics from science.

"I feel that it is very important that these communication channels are kept open because they provide a crucial link between different societies and different peoples during periods of difficulty, and because they can be kept separate from immediate political concerns", Dr Alan Bromley, professor of physics at Yale University and president of the American Association for the Advancement of Science, said on the eve of the association's annual meeting.

At the National Academy of Sciences, which two years ago suspended all bilateral symposia, seminars and workshops with the Soviet Academy of Sciences in protest at the treatment of physicist Dr Andrei Sakharov, but has made no move to interrupt the exchange of individual scientists between the two academies, president Dr Frank Press said he was concerned that if there was no formal scientific agreement at all between the United States and the Soviet Union, it would be difficult to keep channels of communication open.

Even some of the groups which have been most vocal in their protests over the treatment of Dr Sakharov and other dissident scientists have expressed fears that their effectiveness could be severely reduced if scientific exchanges were terminated. Dr Max Gottesman, a member of the Committee of Concerned Scientists, said last week that since Soviet diplomats did not seem to consider the termination of such exchanges to be a major blow to their domestic scientific effort, the United States stood to lose more than it might gain in terms of influence over opinion in the Soviet scientific community.

In contrast, there is less consensus on how far the federal government should go in restricting access by foreign scientists, in particular those from the Soviet Union, to US research laboratories on the grounds that the knowledge they pick up might later be used for military purposes.

Following protests from the scientific community that such restrictions could unnecessarily restrict the flow of scientific information, Mr Frank Carlucci, deputy secretary of the US Defense Department, has provided a detailed list of instances where, he claims, the Soviet Union has achieved significant military or technical benefits through visits to US laboratories made by Soviet scientists on exchange programmes. According to Mr Carlucci, "it is quite apparent the Soviets exploit scientific exchanges as well as a variety of other means in a highly orchestrated, centrally-directed effort aimed at gathering the technical information required to enhance their military posture".

A significant number of scientists are known to be in general agreement with the Defense Department's position. Dr Bromley, for example, said that although he felt restrictions should not be applied to basic science, he was concerned that information of potential military value might have been "given away" through exchange programmes.

The National Academy of Sciences is considering setting up a committee to look at the implications for the scientific community of existing and proposed federal restrictions on the flow of technical data. Dr Richard D. DeLauer, Under-Secretary of Defense for Research and Engineering, is said to be in favour of such a committee, although academy officials fear the government might act before a proper study can be carried out. **David Dickson**

Polish academia only partly normal

Polish academic life formally resumed this week but was, however, only partial. There are reliable reports that only graduate and fifth-year (finals) students have been readmitted to the universities and that all other undergraduate courses have been suspended until next year.

This leaves in doubt the status of the suspended students. A decree of the Military Council, passed on 30 December, obliges all able-bodied males between 18 and 45 years of age to work for the duration of martial law. Students as such are exempt, but it is not clear whether the exemption applies to those who must wait until next autumn to resume their studies.

There are also unconfirmed reports of some first-year students being drafted for military service. University graduates who have not yet found work are obliged to report to plenipotentiaries from the Ministry of Labour, Wages and Social Affairs stationed at their former colleges. Since unemployment among young graduates is considerable — particularly in the humanities and social sciences — there seems little chance that for them the clause in the decree, enjoining the administrators to take professional qualifications into consideration "as far as possible", will be of more than a token significance.

Academic staffs are far from happy with the new situation in Poland. On 23 December, the Prime Minister, General Wojciech Jaruzelski, together with Deputy Prime Minister Mieczyslaw Rakowski and Politburo member Hieronim Kubiak, met 69 leading academics to discuss what Jaruzelski described as "the active role of Polish scientists, intellectuals, writers and artists working for the salvation of the homeland, consolidation of the state and the building of a bridge of special patriotic agreement". Both Kubiak and Rakowski have the reputation of being liberals, and the academics seem to have been selected mainly from those who played little or no active part in the campaign for academic autonomy of the past 16 months.

Even so, no agreement was reached. The official communiqués spoke merely of a "long and frank discussion", with the

0028-0836/82/010003-02$01.00

academics stressing the "urgent need to rebuild trust and calm scientific teaching in Polish universities". According to an unofficial *Solidarity Information Bulletin* now circulating in Warsaw, the seven-hour meeting was deadlocked by the persistent demand of the academics for the release of all detainees and for the participation of the university rectors recently elected under the new democratic procedures in any further negotiations.

The presence at the meeting of Dr Aleksander Gieysztor, president of the Academy of Sciences, must have sharpened the discussion of the detainees. He was himself picked up in one of the early round-ups, although released shortly afterwards.

The unofficial lists of detainees now being compiled reflect just how active a role the academic community played in the Solidarity movement. They include:

- Lecturers from the unofficial Society of Academic Courses (the "Flying University") Stefan Amsterdamski, Wiadyslaw Bartoszewski, Andrzej Celínski, Jerzy Jedlicki and Jan Walc.
- Solidarity advisers from the universities, including Dr Bronislaw Geremek, a Warsaw lecturer in economics, who was a member of the Solidarity delegation to France last October, and Dr Stefan Kurowski who drew up the project for economic renewal discussed at the Solidarity Congress.
- Doctors and medical workers including Grazyna Przybylska-Wendt from the Solidarity presidium.
- Academy or university employees who, until now, have never achieved this type of prominence — among whom Dr Stanislaw Kozlowski, the new rector of Poznan University, is the most eminent so far.

The military rulers seem willing to make some small concessions to the academics — the constitution of the Polish People's Republic (Art.5.3) enjoins them to maintain the "constant progress of science and technology". Academic detainees from the Warsaw area are housed in a government hotel near Drawsko. Earlier reports that Solidarity advisers Jacek Kuron and Adam Michnik had been savagely beaten are unfounded.

The main instigators of the academic turmoil, according to the official statements, were the activists of the Independent Students Union (NZS). These, it is said, had tried to turn NZS into a political organization, rejecting the policy of social accord and "stirring up anti-Soviet sentiments" — a line which suggests that a purge of the student body may be forthcoming.

So far, no mention has been made of the fact that, only a few days before the military take-over, the Conference of University Rectors, meeting in Poznan, had formally endorsed the recent NZS protests as a valuable contribution to the struggle for academic freedom.

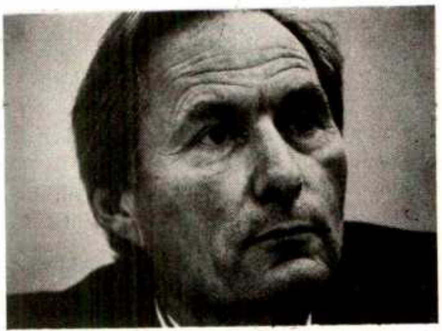
Vera Rich

High-energy physics

All change

With approval for its latest accelerator, LEP, under its belt, the European Centre for Nuclear Physics, CERN near Geneva, seems prepared to experiment — not so much with particles but with its governing body. For alongside the announcement of the CERN budget, and the final approval for LEP (see *Nature* 24/31 December, p.685), comes news of the appointment of two active new characters to the CERN Council. Sir Alec Merrison, currently chairman of the UK Advisory Board for the Research Councils and vice-chancellor of the University of Bristol, is to become president of the council; and Umberto Vattani, a high-ranking Italian civil servant who was involved in a disagreement two years ago between Italy and Germany over the appointment of a German (Professor Herwig Schopper) as director-general of CERN, becomes one of the two vice-presidents.

Sir Alec was himself a high-energy physicist, and in fact in 1959 he was co-author of the first experimental paper to come out of CERN. He was also a director of the now defunct Daresbury electron accelerator, NINA, and has defended the place of "big science" in the highly-constrained UK science budget.



Merrison: chairman everywhere?

On his appointment — which gives him control of the CERN Council's committee and subcommittee work during the next year, as well as presidency at the council itself — Sir Alec said he was delighted at the decision over LEP. "All the delegates are amazed that CERN has been able to pull this thing off," he said, but at the same time the next few years would see CERN taking "a jolly dangerous path".

This is because LEP is to be built out of the current budget only by making massive savings in the present programme. Closing certain facilities entirely would save something, but most of the savings will have to come from running down the experimental work on the CERN 400-GeV super proton synchrotron, the laboratory's biggest machine. There will therefore be a hiatus in research.

Vattani, on the other hand, now reassured that Schopper has proved an "excellent" director, and that Germany will not try to squeeze CERN in favour of its own national accelerators, sees looming problems in personnel and pensions

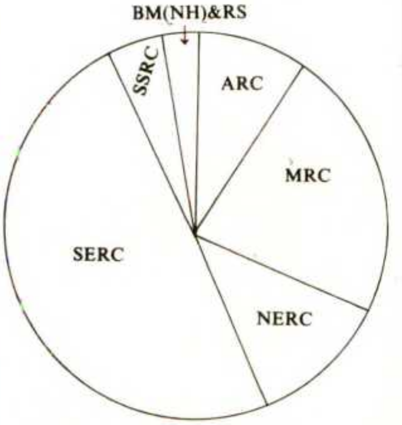
Other questions which will arise for the council in 1982 are late payment (some members have indicated that they may not be able to pay their subscriptions on time) and the management of the LEP project itself. LEP will span two countries, be 27 km in circumference, cost £275 million, and will still face some environmentalist opposition in the region. Professor Schopper will no doubt welcome all the help that the council can give him in this, the largest ever CERN project.

Robert Walgate

Hardly any change

The arguments put forward by the past and present chairmen of the British Science and Engineering Research Council (SERC) that the council should take a larger slice of the science vote have modestly borne fruit. Although the civil science budget for 1982–83, made public a few days before Christmas, has roughly kept its real value, SERC's budget has been increased by about 1 per cent. Most of the council's extra money will be spent on biotechnology, information technology and on helping universities to maintain the quality of research in spite of cuts in their own budgets.

It is equally no surprise that the council to come off worst in this year's division of the science vote is the Social Science Research Council (SSRC), with a real budget for 1982–83 about 4 per cent less than in 1981–82. SSRC has suffered substantial cuts in the real value of its grant for the past three years, reflecting uncertainties about the role of social science research in Britain.



The three other research councils, however, are to receive the same real budget in 1982–83 as in 1981–82. All, however, will be concerned that the government has allowed for only a 4 per cent increase in salaries over the year. If, as last year, the increase in the salary bill is higher, then the amount of research the councils can buy is bound to decrease.

Judy Redfearn

0028-0836/82/010004-02$01.00

American science

Supply-siders now

Washington

"We are now forging a substantially closer relationship with both the legislative and executive branches of Congress", the retiring president of the American Association for the Advancement of Science (AAAS), Dr Alan Bromley of Yale University, said on the opening day of the association's annual meeting in Washington on Monday

Dr Bromley listed various ways in which AAAS was exercising what he described as a "service role" for private and public science decision-makers Such activities range from providing testimony to congressional hearings to preparing regular and widely quoted assessments of the impact of federal policy on the size of the US research and development effort

But if a considerable amount of AAAS's time is now spent helping the government to do its job, there has also been an expansion of effort to compensate for federal actions — for example, the cutting back of support for science education in schools

Following up an initiative launched at last year's annual meeting in Toronto, the chairman of the AAAS board of directors, Dr Frederick Mosteller, announced that the association had just received a $6 5 million grant from Philips Petroleum for a series of television films to complement the work of mathematics teachers in public schools "by making mathematics more lively and significant"

Another educational initiative is the publication of a set of science teacher notes based on articles appearing in AAAS's monthly science magazine *Science 82* The association is also convening two conferences later this year with leaders of various scientific and technical societies, the first dealing with urgent policy issues in science education, the second concentrating on the growing shortage of science and mathematics teachers

Inevitably, a prominent theme of this year's meeting is the impact of the Reagan Administration's cuts in public spending on scientific research In an address on Sunday evening, the President's Science Advisor, Dr George (Jay) Keyworth, emphasized again the Administration's awareness of the importance of basic science, promising that the next "budget submission will clearly reflect that"

He also again warned that there were hard choices to be made In the short term, there was general acceptance at the meeting that such a policy was appropriate Dr Bromley pointed to the Department of Energy's High Energy Physics Advisory Board and the Nuclear Science Advisory Committee as examples of ways that scientists in a particular fields, when finances get tight, have been able to determine their own scientific priorities

But in the longer term, it was said, repeated budget cuts will be severely disruptive Figures produced by AAAS itself last week showed that for the two-year period 1981–82, the result of federal actions will be to reduce the civilian research and development budget by about 16 per cent in real terms (constant dollars), with a 22 2 per cent growth in the military research and development budget over this period

Another issue being hotly debated in the meeting rooms and corridors is the current dispute about creationism and the teaching of evolutionary theory in public schools On Monday morning, the AAAS board unanimously passed a resolution that "creationist groups are imposing beliefs disguised as science upon teachers and students to the detriment and distortion of public education in the United States"

Registration at the 1982 meeting is expected to be about 5,000 which AAAS officials say is approximately the same as the last time the association held its annual meeting in Washington three years ago Next year, in Detroit, they are hoping for something better, by moving the timing of the meeting from January to May

That decision has been partly determined by the weather During last year's meeting, Toronto experienced its coldest winters for almost a century, with temperatures of -30°C The previous year, San Francisco airport had been closed by fog **David Dickson**

UK director for US Biogen laboratory

Dr Richard Flavell, one of Britain's whizz-kids of gene cloning, is to leave the country to become research director of Biogen Inc , the American arm of the international biotechnology firm, Biogen NV

Flavell is currently leader of the only gene cloning group at the National Institute of Medical Research (NIMR), Mill Hill, London, one of the two principal laboratories of the UK Medical Research Council Gene cloning is also done at other laboratories of the council — notably at Hills Road, Cambridge — but there is a strong feeling that application of the technique, central now to the whole of molecular biology, should be more in Britain The loss of Dr Flavell is thus significant, particularly at a time when NIMR is seeking a new director and reconsidering its role within British biology

In fact, Flawell has officially been granted "leave of absence" from Mill Hill for two years, but it seems unlikely that two years hence Flavell will want to leave Cambridge, Massachusetts, where the Biogen laboratory is being set up

Flavell will continue to direct a group at Mill Hill, if at a distance, but he wishes to take some of the more fashionable work with him He expects that half-a-dozen of his Mill Hill team will go with him to Biogen, taking with them expertise on the H-2 regions of the mouse genome These regions code for histocompatibility antigens in the mouse, and it may be speculated that Biogen will now take an interest in the generation of reagents for tissue-typing in man, using the equivalent human HLA regions Flavell will leave at Mill Hill the part of his group which deals with the globin genes, also important in immunology but less at the centre of attention now than H-2 and HLA

At Biogen, Flavell will take over a fledgling staff of 20 scientists, which he will increase to 75 by the end of 1982 He will, of course, be concerned mostly with fostering the commercial interests of Biogen through research, but has been guaranteed the opportunity to pursue his own basic research — largely through the Mill Hill team he takes with him

Flavell cannot say yet what the research interests of his new laboratory will be, but according to Professor Charles Weissmann of Zurich, who is chairman of the scientific council of Biogen, the Cambridge laboratory was originally planned to pay closer attention to the chemical and processing aspects of biotechnology than Biogen's Geneva laboratory which was founded earlier (see *Nature* 27 October 1981, p 599) Whether Flavell will in fact follow this line is open to question

Robert Walgate

Biomedical research

NIH takes a cut

Washington

The National Institutes of Health (NIH) told recipients of biomedical research grants and contracts last week that new and continuation grant awards made in the next three months are likely to be 4 per cent lower than initially proposed by President Reagan in his budget request to Congress last March

It could have been worse A revised budget request, issued in September, demanded a further 12 per cent reduction in all discretionary public spending and many federal agencies have had their activities curtailed significantly in the drive to reduce the federal deficit As it is the NIH budget for 1982 — the fiscal year which started last October — will only increase by 2 2 per cent, considerably less than the current rate of inflation, and the first significant drop in real terms for federal support of biomedical research since the mid-1970s

However, in the short term, no major damage seems to have been inflicted, and

0028-0836/82/010005-02$01 00

NIH's budget strategy of attempting to stabilize the number of new and renewing competitive awards at about 5,000 remains virtually intact Furthermore, Congress has replaced much of the money for research training grants which the Office of Management and Budget wished to cut

Technically, the 4 per cent reduction is only a provisional figure, valid up to March Unable to agree on a detailed appropriations bill, Congress agreed last month to a "continuing resolution" for the next three months In practice, however, since debate on the budget for the 1983 fiscal year begins later in January — and no substantial objection to the provisional 1982 totals are expected from the White House — the 4 per cent reduction is likely to run to September

It has been a confused budget year for NIH Before leaving office in January, President Carter proposed a biomedical budget for the institutes of $3,770 million, a figure left virtually untouched in the Reagan Administration's budget review in March and representing an increase of about 5 6 per cent over 1981 However, realizing that the budget deficit in general was going to be much larger than initially anticipated, the Reagan Administration in September recommended an across-the-board cut of 12 per cent, which would have reduced the NIH budget to $3,310 million

The net result of last month's continuing resolution is that, rather than having to reduce the number of new awards for competing research projects to 4,230, as the proposed September revisions would have required, NIH expects to be able to make almost 4,800 of these during the current financial year This is little short of the 5,000 which was adopted as a goal two years ago, following several years in which the number of such awards, which are provided to support investigator-initiated research projects, had fluctuated widely

The budget resolution procedure thwarted a move supported by several legislators in the House of Representatives to direct additional research funds to three institutes the National Institute of General Medical Sciences, the National Institute of Allergy and Infectious Diseases, and the National Institute of Child Health and Human Development These were felt to be suffering more than the others from the squeeze on research funds, in terms of the quality of the research projects that were being refused funding

NIH officials are optimistic that the 1983 budget which Mr Reagan submits to Congress next month will again contain a small increase for NIH Secretary of Health Mr Richard Schweiker is said to have argued successfully against major cuts in biomedical research that had been proposed by the Office of Management and Budget **David Dickson**

New director chosen for NIH

Washington

Dr James B Wyngaarden, chairman of the department of medicine at Duke University in North Carolina, is expected to be nominated by President Ronald Reagan as the new director of the US National Institutes of Health (NIH) in Bethesda, Maryland

Although yet to be formally announced — and subject to approval by the US Senate — Dr Wyngaarden's appointment is thought to have been unofficially approved by the White House, and the delay in making an announcement is the result of the lengthy security and financial checks which all presidential appointees undergo

Dr Wyngaarden would probably be a popular choice at NIH's headquarters, and with the biomedical research community in general Those who know him say they expect him to provide strong leadership and vigorously to defend the $3,600 million research budget of NIH, the principal source of federal funding for biomedical research in the United States

Dr Wyngaarden has been a close professional colleague of Dr Donald Fredrickson, who resigned as NIH director last July after six years in the post Together with Dr John B Stanbury, the three were co-editors of an influential collection of essays, *The Metabolic Basis of Human Diseases* First published in 1960, the book is about to go into its fifth edition, and is considered by many to be a classic in its field

Dr Fredrickson said last week that he had "no doubt" that Dr Wyngaarden would fill the NIH position extremely well "He is a good physician, an excellent scientist, and understands the institutional aspects of medical research very well, I have every confidence that he will be an excellent director"

A graduate of the University of Michigan, Dr Wyngaarden is no stranger to Washington science policy circles He was a consultant to the Office of Science and Technology Policy between 1966 and 1972, and a member of the President's Science Advisory Committee from 1972 until its abolition in 1973 Before his appointment at Duke, he was professor of medicine and chairman of the department at the University of Pennsylvania from 1965 to 1967

NIH scientists hope that a speedy confirmation of Dr Wyngaarden's appointment will help to accelerate other senior appointments at NIH Six of the twelve institutes lack a permanent director, and approving the new appointments will be one of the first tasks awaiting the new director

David Dickson

Molecular biology

Trimming costs

Molecular biologists who are used to relying on the European Molecular Biology Organisation for providing fellowships and other useful means of mobility within Europe may have to pay closer attention to the politics of its budget next December — for the 1982 budget has seen a 3 per cent fall (in real terms) for the second year running

The secretary of the organization, Dr John Tooze, says that management costs have been trimmed to the absolute minimum, and that for 1982 cuts will have to be undertaken in the EMBO programme itself The 1982 budget will be DM 3 5 million (£825,000), numerically 8 per cent above last year but 3 per cent below EMBO's calculated inflation figure

The EMBO scheme accounts for 400 fellowships in any year, plus 40 courses and workshops and a small lectureship programme — which often takes prominent American and other visiting scientists around Europe on a lecture tour It is this lecture programme which is likely to be cut this year

If the budget were to be cut again for a third year, the fellowships and workshops would be hit, says Tooze Then the smaller countries (of the 17 member states of EMBO) would certainly object These countries are probably the main beneficiaries of the programme, and they in fact constitute a two-thirds majority of states on the council which votes the budget of EMBO each year Decisions can be taken by such a majority but the remaining states — Britain, France, Germany and Italy — contribute nearly 60 per cent of the budget The danger is that if the small countries kick up a fuss, the big four could refuse to pay This year a compromise has been reached It may not be so easy next year

Microbial collections

Bugs in hazard

Once again, a British microbial culture collection is threatened by lack of funds At the end of last year the Ministry of Agriculture, Fisheries and Food announced its intention to withdraw support for the National Collection of Industrial Bacteria housed at the Torry Research Station in Aberdeen This is the third time in two years that culture collections have been threatened by withdrawal of funds The Brewery Research Foundation and the agriculture ministry have already stopped supporting the national yeast culture collection and the Commonwealth Mycological Institute and Natural Environment Research Council have said that they wish to cut support for the national fungi collection

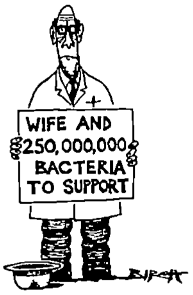
Although the problems of the yeast and fungal collections have been at least

0028-0836/82/010006-02$01 00

temporarily solved, the threat to the industrial bacteria collections has stimulated the UK Federation of Culture Collections to urge that a single government agency should take over responsibility for all of Britain's ten national collections. The problem is that the collections currently share seven sponsors, not all of which ascribe high priority to their sponsorship.

In the event, the industrial bacterial collection may also be saved, though not necessarily to the satisfaction of its users. The most likely outcome is that the agriculture ministry, the collection's sole sponsor, will relinquish responsibility to the University of Aberdeen from next April. Negotiations are under way for transferring the collection to the university's company, which handles the commercialization of research relevant to industry. The idea is that the collection should eventually operate as a commercial concern.

Under the arrangements now being discussed the ministry would pay the university for running the collection, although payment would be considerably less than current running costs of about £200,000 a year. Savings would be achieved largely by reducing the number of staff from twelve to about seven. Still to be determined are the university's commission on continuing business, the ministry's initial grant and what should be charged for consultancy and services. Although the proposal would save the collection, the microbiological community, which fears that commercialization could jeopardize some of the services currently on offer and increase costs to users, is glum about the prospects.



Last year, an inter-research council committee was set up to deal with the funding problems of culture collections as and when they arise. But the UK Federation of Culture Collections now argues that the committee's remit is too narrow. Together with three learned societies, including the Society for General Microbiology, the federation is hoping to persuade one government agency to take over responsibility for all ten microbial collections and to coordinate the formulation of a national policy for genome conservation including plant and animal cell lines as well as microbial cultures. As yet, however, no obvious agency has come forward, although the federation is hopeful that a meeting with the Department of Industry early in the year will be fruitful.

Stanford University

At the helm

Palo Alto

When biologist Donald Kennedy became Stanford University's eighth president in August 1980, he pledged strong support for the humanities. Now, more than a year later, he has delivered. $5.6 million in gifts and grants have helped to create a new Humanities Center. From other contributions, eight professorships have been endowed.

Nevertheless, some faculty members remain sceptical of Kennedy's efforts to make support for the arts and humanities comparable with that for the sciences. One humanist complains that too much time is spent on training and not enough on students' personal development. He thinks that a university should be primarily concerned with values. He is waiting for Kennedy to enunciate his values and to exert intellectual leadership. "You can buy administrative ability", the disgruntled professor believes.

During Kennedy's spell in Washington as Commissioner of the Food and Drug Administration, he won wide respect for his administrative ability. Although he denies rumours about his own political ambitions, he still travels frequently to the capital.

He says that one of his objectives is to improve government understanding of the kinds of problems research universities face and about national science policy. He has the experience and the contacts to talk about these matters in the right places.

And lean, six-foot-one Kennedy believes that Stanford will be able to continue as a first-rate centre of basic research in spite of federal research cutbacks this year of 2 or 3 per cent. He is a self-avowed "relentless optimist". Nevertheless, he worries about reduced support for student financial aid. More than half of Stanford's 12,800 students receive scholarships. Research and training should go hand in hand, a truth not always recognized by the Reagan Administration, Kennedy says.

Kennedy remains doubtful that private support for universities will help to cover the gap created by diminished federal funding. Although private support for research has grown, it amounts to only 3.5 per cent of Stanford's total research budget of $130 million a year.

The success of Stanford's own venture in commerce is necessarily still unclear. Last month, 71 companies signed licences for the gene-splicing and cloning patents developed by Stanford geneticist Dr Stanley Cohen and University of California biochemist Dr Herbert Boyer. Both scientists have made over their share of royalties to their universities. Initially, the licensing will yield $710,000 annually, but the long-term potential could be much higher.

Donald Kennedy keeps ahead

In the face of his campus's burgeoning biotechnology, Kennedy spends much of his time on the ethical questions of proprietary research. He has organized a conference in March with administrators, faculty scientists and representatives of industry to establish possible guidelines for the future. His own interest in science policy stems from his work as a founder of the human biology programme at Stanford. He was chairman of the biology department in 1965–72. His colleagues consider him a brilliant administrator and a fine scientist, able to articulate his views clearly.

Although a member of the National Academy of Sciences, Kennedy does not expect to return to the laboratory. His speciality is the neurophysiology of behaviour. He continues to work on two unpublished papers about how connections among nerve cells are responsible for fixed behavioural acts.

Meanwhile, he enjoys his contact with students and giving guest lectures, as well as advising eight freshmen. He has a reputation as an outstanding and entertaining lecturer. Thus, to illustrate man's evolution from the primitive fish *Amphioxus*, he will sing to the tune of "It's a long way to Tipperary",

Goodbye fins and gill slits,
Hello teeth and hair.
It's a long way from *Amphioxus*,
But we came from there.

Kennedy is blessed with enormous energy. But some of his faculty grumble that he is too enthusiastic, that he is also too generous, and that he resorts too quickly to resolving disagreements with university funds.

Students nevertheless like him. Graduating seniors have repeatedly asked him to address them. He attends more than 24 sherry parties annually in student dormitories.

Will his present enjoyment of his leadership of Stanford last? A close associate suggests that within five years Kennedy will start to think about a new post. It takes that long for the excitement and pleasure of the office to begin to dissipate.

At present it is possible to find Stanford's president at 6.30 a.m. each Tuesday and Friday morning running four miles over hilly terrain. Those who wish to discuss problems or to offer suggestions are welcome to join him. Most of his colleagues agree that one has to be pretty swift to outrun him.

CORRESPONDENCE

The ultimate question

SIR — G K O'Neill's statement that we are probably alone in our galaxy (*Nature* **294**, 25, 1981) is based on two different arguments — one about the unlikeliness of the phenomenon of life and the second about the probability of the development of space colonies by any long-lived civilization I show here that there is an unexpected link between the two arguments

It may well be true that the survival of life on Earth is due to an extraordinarily lucky series of accidents by which the surface temperature remained remarkably constant On the other hand, J E Lovelock's suggestion that life itself was and is responsible for the maintenance of a life-friendly temperature, is not without evidence In his book *Gaia, a New Look at Life on Earth,* Lovelock wrote that the fact that the Earth's climate has changed very little since life appeared, despite variations in the output of heat from the Sun, was one of the reasons for developing the Gaia hypothesis This hypothesis proposes that "the entire range of living matter on Earth, from whales to viruses, and from oaks to algae, could be regarded as constituting a single living entity, capable of manipulating the Earth's atmosphere to suit its overall needs and endowed with faculties and powers far beyond those of its constituent parts" In another version of the Gaia-hypothesis Lovelock calls this entity an organism, but he prefers to talk about the "Gaia system" The word "organism" is indeed confusing when used to refer to an entity of which the constituent parts are organisms But I see no reason why this "Earth life system" (having assumed its existence) shouldn't have the property that distinguishes living systems from dead matter, namely the capability to procreate

O'Neill's second argument — "The development of space colonies is a natural and not particularly difficult stage in the development of any intelligent civilization" — can be rephrased, if we are prepared to admit that the human species and its technology is integrated in the whole of living nature, to read "The development of space craft is a natural process in every planetary life system and will lead to the creation of independent descendants (space colonies), so to ensure the pre-existence of the planetary life system"

So — is there an association between the hypothesis of an overall "organism" and the (also hypothetical) development of space colonies? It is a question that goes beyond science, and gives us a choice between heroic antropocentrism and a more objective but difficult to accept biocentrism

ROELAND A DE BIE

Rotterdam, The Netherlands

Base mettle

SIR — I was pleased to note that your editorial staff has at last discovered the greatest of American sports as reported in your column "Shame on New York" (*Nature* 5 November 1981, p 2) While your comments on the competition " quaintly known as the 'World Series" were touching and amusing, I was surprised to note a large number of errors of fact in the column Given *Nature's* reputation as a scientific journal, I am sure you will want to waste no time in correcting these

You suggested that good players are able to hit one fair ball in three Actually, good players will hit about 8 fair balls in 10, with about 3 in 10 resulting in safely reaching the first base A player who could hit only one fair ball in three would shortly be sent packing for another sport where his talents might be more appropriate to the level of play (cricket perhaps?)

You noted that the Yankees were not as skilled in catching and throwing the ball as the Dodgers This is a strange comment on an event in which one member of the Dodgers set the all-time record for most errors (serious mistakes in catching or throwing) in the "World Series" One might also have noted that members of the New York Yankees Baseball Club, once "on base", displayed a remarkable propensity for running directly towards the Dodger player in possession of the ball The only biological parallel I can think for this behaviour is that of certain species of whales running themselves aground and eventually perishing of their own weight In the interests of science, *Nature* might humbly have suggested that representative members of the Yankees should be selected for inner ear examinations or behavioural analysis during the winter I believe that Mr Steinbrenner has made similar suggestions, couched in rather different language

Finally, *Nature's* comments on the random flight of the batted ball are completely innaccurate Every baseball player is aware that while the flight of any individual batted ball is unpredictable, when a large sample of batted balls from any one individual is examined, certain patterns emerge As more and more samples are taken, a pattern of probabilities (not unlike probability patterns in electron orbitals) can be assembled and a definite and nonrandom distribution becomes clear In the case of the Dodgers, these functions fell quite frequently beyond the bounds of the playing surface In the case of the Yankees, the result of swinging the bat was that all too often the probability function for position of the batted ball reached a maximum in the glove of the catcher

KENNETH R MILLER

Brown University,
Providence, Rhode Island, USA

Another contender

SIR — I note the absence of contributions on systems ecology to your debate on evolution

The branching tree is a forceful image of evolution which has proved reasonably compatible with the limited evidence of the fossil record Recently, some palaeontologists engaged on rigorous studies of fossil lineages have come to crave some theoretical innovation which would better model the history of evolutionary progress[1] They may be suspected of trying to induce innovation by creating what they consider to be favourable conditions for an ideological revolution that is, by promoting a theory of "punctuated equilibrium" as an antithesis to "gradualism" So far, the rather unsurprising product gleaned from articles in your journal is that evolution can occur at varying rates[1,2] It also appears that evolutionary progress by punctuation of an equilibrium does not require a qualitatively different type of evolution from that predicted by the genetic theory[2]

Rates of evolution seem to depend largely on the rate of change in selective stress, which results from a changing environment for example, the gradual evolution of a species supposes gradual change in environment However, the range of physical environments has remained fairly uniform through time their geography may change but this is usually accommodated by a mobile biota New forms which evolve in small isolated populations under environmental stress are likely to be shortlived when their isolation breaks down and normal conditions return they are likely to be out-competed by more broadly adapted and numerous "ancestor" species

In contrast, the biological environment has a capacity for accretionary change[3] "Gradualists" should look to the progressive development of biological systems for their selective pressures Proponents of punctuated equilibrium might investigate the instabilities which are likely to be inherent in such systems

Is this a record?

SIR — A recent paper by Sadler[1] shows that the stratigraphic record of geological time is very incomplete In commenting on this, van Andel[2] notes that contemporary evolutionary theorists ascribe major evolutionary steps to a jump advance or "punctuation" — concentration of major change in a brief time interval

If major change happens rapidly, and rapid events are rarely preserved in the fossil record, it follows that most major evolutionary events are beyond study because they have no stratigraphic record But the actual *evidence* for a punctuational view of evolution depends on literal reading of the fossil record, that is, the assumption that gaps between successive stages of the stratigraphic record are insignificant[3] If gaps represent more time than fossiliferous strata do, gradual transitions between species will necessarily appear punctuated

Sadler himself noted "In their treatment of the fundamental character of biological evolution, Eldredge and Gould (1972) are concerned with the completeness of the record Unfortunately they tackle only the question of the abundance of fossils It is equally important to determine whether the completeness of the sediment accumulation is adequate for the recognition of 'punctuations' in the fossil record that are phyletic in origin rather than indicators of sedimentary lacunae We have attempted to quantify the sedimentary aspect, these numbers need to be matched by estimates of the duration implied by 'punctuations' "

Reservoirs and the triggering of earthquakes

from Peter J. Smith

In spite of early doubts, it is now well established that large reservoirs can generate earthquakes. When the possibility of reservoir-induced seismicity was first mooted during the mid 1960s, it was greeted with scepticism in some quarters, largely because comparable before-and-after records for the few examples then known were unavailable. Systematic seismic surveys had only been started after impounding was under way or even, in some cases, complete, and so the details of the pre-reservoir seismic background were uncertain at best. A scientifically rigorous presentation of the evidence was therefore impossible, even though in one spectacular case (Koyna, India, 1967) a large reservoir had clearly given a relatively aseismic zone the ability to kill.

But there are no doubts now, for well documented examples of reservoir-induced seismicity are known throughout the inhabited continents. In general terms, what happens is that the huge mass of water in a reservoir changes the stress patterns in the underlying rocks. The water load exerts a simple vertical pressure on the rocks immediately, whilst the pore pressure in them increases gradually as the water infiltrates at a rate that depends on their permeability and prior water content. In addition, the water reduces the rocks' coefficient of initial friction and in the longer term can change their chemical, and hence physical, properties by weathering. Even so, it is widely held that such effects are not by themselves sufficient to generate earthquakes in zones not already subject to tectonic stress. The role of the water is rather to trigger seismic events in a highly stressed system close to break point.

This is clearly the case in the Tadjikistan region of the USSR, where the Nurek reservoir has been generating seismic activity since filling began in the early 1970s. In this, as in a number of other cases, the induced seismicity is not related directly to the absolute amount of water present but to variations in it. Bursts of seismic activity are triggered when the water level changes, the intensity of the activity increasing with the rate of level change. The temporal fluctuations in the seismicity are thus easily related to the fluctuations in the phenomenon inducing it.

The spatial distribution of the seismic activity, by contrast, is less straightforward. Most of the induced earthquakes occur beneath the central part of the reservoir and upstream (southward) from it. The region containing that half of the reservoir immediately behind the dam, on the other hand, is almost completely aseismic. Yet both the seismic and aseismic zones are lithologically similar, consisting largely of Upper Cretaceous to Palaeogene shallow-water limestones interbedded with mixed components of shale and gypsum. What, then, governs the location of the induced seismicity?

The answer, as Leith *et al* have discovered (*Geology* 9, 440; 1981), lies in the varying structure and the different permeability regimes to which it leads. The limestone units in the region beneath the reservoir are highly fractured and thus relatively permeable, whereas the gypsum and shale units have very low permeability. The alternation of permeable and impermeable strata thus gives rise to a strongly directional overall permeability. Normal to the bedding the overall permeability is very low because the largely impermeable layers prevent, or severely restrict, water transport. Parallel to the bedding, however, the permeability is high because the water can easily diffuse along the permeable layers. In other words, in their originally horizontal configuration the strata would have prevented most vertical fluid migration.

The strata beneath the Nurek reservoir are no longer horizontal, although immediately upstream from the dam the effect is little different. Here the alternating layers of limestone and gypsum–shale are folded into a syncline. Any water entering one of the permeable layers could migrate to the bottom of the basin formed by that layer but would be prevented from moving any further in the vertical direction by the impermeable rock layer beneath. In this region, therefore, water cannot enter the vast mass of rock below and cannot thereby change the pore pressure. The reservoir here acts only as a load, which is insufficient to induce seismicity.

Further upstream from the dam, on the other hand, the strata are folded into a moderately plunging open anticline with the dip in the upstream direction. In this region water entering a permeable layer can diffuse along it and thus be carried to various depths without restriction. Here the pore pressure at depths does change and is sufficient to generate seismicity.

What all this amounts to in the end, of course, is yet another version of the old, old story, namely, that general geological processes governed by universal physical laws will nevertheless lead to unique consequences depending on the particular environment in which the processes take place. As far as reservoirs are concerned, it is known that the large masses of water involved can generate earthquakes, but whether and precisely where they will actually do so depends critically on local conditions.

The Nurek case shows that the pattern of induced seismicity rests upon very local conditions indeed. The lithological environment in the Nurek area is not unusually inhomogeneous on a regional scale, yet the distribution of seismic activity varies on a subreservoir scale. The obvious conclusion is that if the environmental effects of future reservoir impounding are to be predicted accurately, it will be necessary to investigate the rocks underlying the sites in no less detail. ☐

How eggs breathe while avoiding desiccation and drowning

from Jared M Diamond

An avian egg is an almost self-contained life-support system providing all the nutrients, minerals and water necessary for the embryo's development All that is required from the outside is oxygen and heat The design of an egg involves numerous compromises It must be strong enough to resist accidental breakage, yet fragile enough for the embryo eventually to break out It must lose exactly the right amount of water during incubation neither so much that the embryo dries out, nor so little that it drowns in its own metabolic water The egg must be sufficiently impermeable to prevent drying out, yet sufficiently permeable that the embryo can acquire oxygen and get rid of carbon dioxide The egg's incubation time must be geared to its metabolic rate, size and parents' time budget The egg's size and nutrient content must be geared to the embryo's size and developmental state at birth, and perhaps to the clutch size How is all this possible?

Answers to many of these questions have come from 13 years of work at the State University of New York at Buffalo, by Hermann Rahn, Charles Paganelli, Amos Ar* (of Tel-Aviv University) and their colleagues[1] Their interest in eggs began when a new student innocently asked how eggs breathe As they had never thought about this problem, they began studies which eventually yielded the answer by diffusion The rate-limiting barrier to the egg's gas exchange is the egg shell itself, through which gas transport is diffusive, not convective Oxygen, carbon dioxide and water cross the shell at rates proportional to their gas-phase diffusion coefficients Since these gases follow identical diffusion paths, measurement of the egg's conductance to one (K_{O_2}, K_{CO_2}, or K_{H_2O}) lets one calculate the other two conductances Water flux may be simply measured as the weight loss of an egg kept in a desiccator and egg conductances for 61 species of duck[2] and 84 other species of birds[3] have been measured in this way

Diffusion occurs through microscopic pores arising from imperfect packing of the calcium carbonate crystals that make up the egg shell The pores can be visualized by putting an egg in water in a closed jar connected to a vacuum pump gas bubbles emerging over the whole surface of the egg mark the pores Underneath the shell lie two membranes of protein fibre meshwork, in turn resting on a tissue sheet called the chorioallantois in whose capillaries the avian embryo's gas exchange occurs

Bird eggs vary in size from the 300 mg of a small hummingbird to the 9 kg of the recently extinct elephant bird of Madagascar, and in incubation period from 11 to 80 days It is therefore astonishing[4] that *all* eggs lose 15 ± 2 5 per cent of their initial weight during incubation[1] As Ar and Rahn point out, the fixed water loss ensures that the egg maintains constant relative water content throughout incubation, in the face of metabolic consumption of dry matter (mainly yolk fat) and accompanying production of metabolic water Without water loss, the embryo would drown Yet why is egg water loss so constant among species, when yolk content varies with species from 14 to 67 per cent? One might guess, although it is as yet untested, that the critical variable is constancy of the embryo's tissue osmolarity — for an embryo sealed within its egg, the only means of osmoregulation is water loss

But how do different eggs ensure similar water losses? The explanation, from measurements of egg K_{H_2O} in dozens of species, proves to be that K_{H_2O} increases in direct proportion to egg weight (not to egg surface area) and in inverse proportion to incubation time K_{H_2O} is determined by knA_p/L, where n is the number of pores, A_p the mean area of individual pores, L the pore length or shell thickness and k a constant The shell and its pores are synthesized just before laying and do not change during incubation Bigger eggs have thicker shells and lower pore density but wider pores and greater fractional pore area A 10-fold increase in egg mass is associated with a 2 7-fold increase in shell thickness, an 18-fold increase in total pore area and thus a 18/2 7 = 6 5-fold increase in K_{H_2O}

Eggs of the Wedge-tailed Shearwater (*Puffinus pacificus*) and chicken, for example, are of similar size (58 *vs* 54 g), pore radius (7 6 *vs* 8 0 μm) and shell thickness (0 27 *vs* 0 35 mm), and achieve similar water losses by the time of hatching (14 *vs* 15 per cent), despite the fact that the incubation period is two and a half times longer in the shearwater (52 days) than in the chicken (21 days) This result is achieved through the shearwater having many fewer pores (3,700 *vs* 12,400 per egg), hence lower water conductance[5] (6 1 *vs* 14 4 mg H_2O per day, torr) Chickens and Red-winged Blackbirds living at high altitudes, where water loss would otherwise be high because of low atmospheric pressure and high gas diffusion coefficients, have shells with lower total pore area and lower K_{H_2O} than sea-level populations, and hence have similar water loss during incubation[6]

Regulation of water loss during incubation implies regulation not only of shell K_{H_2O} but also of nest humidity Continual release of water and CO_2 tends to humidify the nest as well as to raise nest P_{CO_2} Water vapour pressure in the nest air is always above ambient, as Rahn, Ackerman and Paganelli[7] documented by an ingenious 'egg hygrometer' This consisted of an egg emptied of its contents, refilled with desiccated silica gel, placed in the nest under the brooding adult, weighed after several days and calibrated by weighing after storage in desiccators at known relative humidities The result all nests were maintained at water vapour pressures of 18–26 torr, although the species studied ranged from Alaskan gulls and Mexican desert island gulls to ducks and songbirds Does the brooding adult measure nest microclimate and then ventilate the nest to maintain the required rate of egg water loss, ventilating more rapidly as ambient humidity rises towards nest humidity? Is the water vapour gradient chronically abolished in species nesting in humid habitats such as moss forest of tropical mountains?

One group of birds violates these patterns the mound-builders (family Megapodiidae) of New Guinea, Australia and adjacent islands Unique among the world's birds, their eggs are not incubated by body heat but by external heat sources, including volcanoes and solar radiation Several species bury their eggs in enormous mounds of rotting vegetation, which they build so that the heat of fermentation maintains a temperature of 37°C (see refs 8–10 and the figure) The humidity in these mounds is saturated The water conductance of eggs of the mound-builder *Alectura lathami* is nearly triple that of a 'normal' egg of the same size and incubation period, due to an unusually thin egg shell[11] The megapode embryo avoids suffocating in the high CO_2 levels (9 per cent CO_2!) and low O_2 levels (14 per cent O_2) in the mound, escapes drowning in its metabolic water, and still musters enough energy on hatching to spend two days digging its way up through a metre of dirt to the surface The eggs of hole-nesting and burrow-nesting birds must also be able to deal with similar problems of gas exchange

As one would expect, the metabolic rate of an egg (rate of O_2 consumption, Q_{O_2}) increases with egg size But metabolic rate also decreases with incubation time, this is because water conductance decreases with incubation time, and as O_2 and H_2O traverse the shell by the same diffusion path, an egg of long incubation time must also have low O_2 conductance Thus eggs of any size and incubation time not only lose a fixed relative amount of water (15 per cent) but also gain a fixed relative amount of O_2, 100 cm^3 per gramme of egg, over the

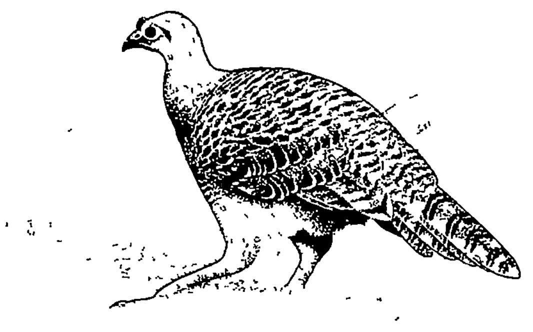
The Mallee Fowl, one of Australia's mound-builders In April or May, parent birds begin digging a pit that eventually measures 10 feet wide and 3 feet deep, and rake plant litter into it With the early spring rains in August the litter begins to decompose and the birds cover it with a mound of sand up to 3 feet thick The female lays eggs one at a time, in the mound, throughout the spring The male is responsible for regulating the temperature of the eggs during the spring he opens up the mound to let excess heat escape from the compost, in summer he piles more sand onto the mound during the day to insulate the eggs from excessive heat from the Sun, and each morning opens up the mound to dispel any heat remaining from the previous day, by autumn the compost has nearly stopped fermenting and the male opens up the mound each day so the eggs can be heated by the Sun, each evening he covers the eggs with warmed sand By April all the eggs will have hatched



from Tim Halliday *Vanishing Birds* Penguin, 1980

incubation period[12,13] The metabolic rate is geared to the incubation time and delivers a finished chick by hatching time, whether 11 or 80 days after laying time

The energy for this metabolism comes, of course, from the yolk But not all eggs are equally endowed Altricial eggs (ones whose chick hatches in a helpless state, at an early stage of development) contain only 24 per cent yolk, so that the egg is 84 per cent water, only 6 per cent lipid and offers only 1 1 kcal energy per g weight Precocial eggs (whose chicks hatch able to fend for themselves, at an advanced stage of development) contain on the average 40 per cent yolk (67 per cent in a mound-builder), consist of 75 per cent water and 10 per cent lipid, and offer 1 9 kcal energy per g weight[14] A parent can give its chick a head-start either by producing an egg with higher yolk content or just by producing a larger egg Conversely, if a head-start is not important, a typical altricial egg saves its mother 80 per cent of the cost of manufacturing a typical precocial egg, through reduction in egg size and yolk content

The questions posed by eggs seem endless Large birds tend to lay large eggs, but egg size varies fivefold among birds of similar size belonging to different orders[15] Why, among parents weighing 100 g, does a parasitic cuckoo produce a 4 5-g egg, an owl an 11-g egg and a petrel a 21-g egg? Evolutionary biologists debate this question, as well as the puzzle why the variation in incubation time from 11 to 80 days includes a large component independent of egg size, and the question of which variable among egg size, metabolic rate, incubation time and developmental state at hatching ultimately determines the others Bioengineers debate why the relation between total weight and skeletal weight has a similar slope but a different intercept among bird eggs, molluscs, spiders, land mammals and whales[16] Students of insects, reptiles, amphibia, fish and the duck-billed platypus have barely begun to explore for eggs of these animals the questions that Rahn, Paganelli, Ar and colleagues have illuminated for bird eggs □

Sexual differentiation and H-Y antigen

from P N Goodfellow and P W Andrews

AMONG the many problems still awaiting the application of the new techniques of molecular genetics is that of mammalian sexual differentiation The question can be simply phrased – why are males male and females female? Analysis of individuals with abnormal numbers of sex chromosomes indicates that the presence of the Y chromosome usually correlates with primary male characteristics[1] It has been suggested that this correlation is due to expression of the H-Y antigen controlled by the Y chromosome[2,3]

The study of the 'H-Y antigen' began with the observation that females from inbred strains of mice can reject skin transplanted from male mice of the same strain[4] As the only qualitative genetic differences between the mice is that the Y chromosome is present in males but not in females, the antigen responsible for the graft rejection was termed histocompatibility-Y, or H-Y, antigen[4] Although it is possible to use the transplantation assay to demonstrate that simple hormonal differences are unlikely to be responsible for the expression of H-Y antigens by males[6], detailed investigation is hampered by difficulties in quantification and limitations in the use of transplantation assays in outbred species, such as man

Serological definition of H-Y antigens

An important advance was made when Goldberg and colleagues showed that sera from female mice which had rejected male skin grafts are cytotoxic for sperm in the presence of complement, and that this activity can be absorbed by male but not female mouse cells[7] The antigen(s) recognized serologically in this way is also called H-Y, although it has not been shown whether the same determinant is being detected in the two different assays Indeed, in a mutation experiment Melvold *et al* have observed one male mouse, unfortunately sterile, that appeared H-Y negative by the transplantation assay, but was serologically H-Y positive[8] Unfortunately the only cells that are susceptible to complement-mediated lysis by these anti-H-Y sera are sperm, which are difficult to read-in the usual cytotoxicity assay, and tail skin epidermal cells[9], which are difficult to obtain Nevertheless many other cell types specifically absorb this activity, and by the absorption of syngeneic murine female anti-male sera followed by testing the residual activity on mouse sperm, serologically detected H-Y antigen is found to be strongly conserved and to be expressed on the male cells of all mammalian species tested Conservation of this determinant is also seen in animals other than mammals where H-Y antigen is found to be associated with the heterogametic sex (in mammals, males are heterogametic having X and Y sex chromosomes, whereas in birds the female is heterogametic having the so-called ZW sex chromosome constitution)[10]

This conservation and the association with one or other sex led to the suggestion that H-Y antigen was concerned in directing the organogenesis of the heterogametic gonad[2] Evidence for this has been presented and discussed elsewhere[3] Suffice it to say here that in mammals the presence of testicular tissue has generally been shown to be associated

P N Goodfellow is in the Imperial Cancer Research Fund Laboratories, Lincoln's Inn Fields, London WC2A 3PX, and P W Andrews is in the Wistar Institute, Philadelphia, Pennsylvania 19104

0028-0836/82/010011-03$01 00

with the expression of H-Y antigen, irrespective of genetic (that is, XX or XY chromosomal constitution) or phenotypic sex The converse case – the expression of H-Y antigen being associated with the presence of testicular tissues – is not always true Two explanations for individuals being H-Y antigen positive but without any testicular differentiation have been offered either the H-Y molecule is 'functionally' absent (for example, the functional part of the molecule has been mutated while it remains immunologically active, or the H-Y receptor on the target cell has been inactivated) or testicular differentiation could depend on the quantity of H-Y antigens produced, a critical level required for the induction of testicular differentiation not being reached

Technical difficulties with H-Y serology

The serological description of the H-Y antigen as outlined above is well established but this does not mean that H-Y serology is without difficulties These result from two technical problems The first is due to the sperm cytotoxicity test, which is one of the most difficult serological assays to perform The extreme reactivity of sperm with naturally occurring heterophile antibodies requires careful control not only of the H-Y antisera but also screening and absorption of the serum used as a source of complement Even the scoring of the sperm cytotoxicity test is difficult sperm are mobile and very small and it is not easy to distinguish between dead and live sperm In addition, there is often only a small difference between a positive and a negative result as the maximum kill in the assay is usually only 50–60 per cent, whilst the background kill in absence of any sera may be as high as 30 per cent Unfortunately, the alternative assays used to detect H-Y antigen, which include every imaginable variation of cell surface immunological detection techniques[11], all seem to suffer from similar problems of high backgrounds and low maximum reactions Undoubtedly this is due in part to the low surface density of H-Y antigen on many cells but it is also due to the poor-quality low titre of the anti-H-Y sera Even after repeated immunization many female mice fail to make H-Y antibodies and those mice which do respond produce low titre antisera This leads to the second problem — the small amounts of antisera that are available

The paucity of H-Y antisera has two adverse effects The first is a reduction in the exchange of antisera which is needed to standardize anti-H-Y reagents and to demonstrate that all H-Y assays are recognizing the same antigen(s) The second effect is to produce an understandable reluctance to perform quantitative absorptions (that is, multiple absorptions with varying numbers of cells), rather than the single point absorptions usually performed Quantitative absorptions are essential for the proper quantification of the amounts of H-Y antigen present This is especially important when studying cells with postulated intermediate amounts of antigen, such as has been proposed to explain the recessive inheritance of male sex-determining genes in the polled goat and in humans[12,13].

An additional problem arises with the recently introduced H-Y test based on the complement-mediated killing of Raji cells (a male human, Burkitt's lymphoma line) by antisera from female rats immunized with male rat cells[14] In this xenogeneic system absorption of anti-human heterophile antibodies is essential to ensure meaningful results Furthermore, even if this absorption is carried out satisfactorily, there is no assurance that the antigen detected by the male-specific absorption of the remaining antibodies is the same as the antigen detected by absorption of syngeneic mouse serum tested on sperm, merely because they both appear to be male associated

Conflicting results of H-Y typing

The technical difficulties and differences in methodology described above may explain the apparent contradictory results reported by the group in Freiburg associated with U Wolf and U Muller and by the workers in New York associated with S Wachtel and G Koo The German group has demonstrated that females with Turner's syndrome (those lacking one of the two X chromosomes found in normal females) express H-Y antigen, although at reduced levels compared with males[16] A similar situation has also been described in mice[17] Based on these results Wolf and his colleagues have suggested that the H-Y antigen is coded by a structural gene on an autosome, that this gene is induced by an activator coded by a Y-linked gene, and that it is repressed by the product of another regulator gene located on the short arm of the X chromosome which escapes X-inactivation in normal females They further propose that interaction of these genes can lead to continuously variable levels of H-Y expression, depending on genotype, and that a certain threshold level of H-Y is required to induce testicular differentiation[16,18] One problem is that they would predict that an excessive number of X chromosomes in a Y chromosome-carrying individual would produce sufficient H-Y repressor to overcome the activator produced by the Y chromosome, such an individual should exhibit female characteristics Nevertheless 49 XXXXY individuals with apparently male phenotype have been observed[19]

Contrary to these ideas is the older hypothesis that the H-Y antigen is specified by a gene or genes normally located on the Y chromosome H-Y antigen-positive XX males, such as are caused by the *Sxr* gene in mice, or the *Polled* gene in goats, are explained by a postulated translocation of H-Y genes from the Y chromosome to an autosome, a suggestion which has received support from molecular analysis of sex chromosome-specific DNA sequences in sex-reversed mice[20] Threshold levels for H-Y antigen activity and, perhaps multiple H-Y genes, are needed to explain why the sex-reversal properties of *Sxr* in mice are dominant whereas they are recessive in the case of the *Polled* gene in goats

Consistent with Y-linkage of the H-Y structural gene is the finding that female Turner's syndrome patients with deleted or rearranged Y chromosomes can be either H-Y antigen positive or negative[21] In particular, two patients have been described that have a Y isochromosome of the long arm These patients are H-Y antigen negative[21, 22] It is difficult to understand why XO Turner's syndrome patients are H-Y antigen positive if XYp-Turner's syndrome patients are H-Y antigen negative

Another possible point of contention between the two groups is the recent suggestion by the German group that XY fertile female wood lemmings do express H-Y antigen[23] In this species karyotypic analysis has demonstrated that some fertile females have a Y chromosome and an abnormal X chromosome, designated X* As these individuals are normally fertile, wild populations of wood lemming contain XX, XX* and X*Y females The earlier studies of Wachtel *et al* suggested that X*Y wood lemming females are H-Y antigen negative and that the abnormal X* chromosome carries a suppressor of H-Y antigen expression[24] The recent experiments yielding the opposite results (X*Y females being H-Y antigen positive) have led Wolf and Muller to propose that H-Y antigen affects its target cells via a receptor that is specified by an X-linked gene and that this gene has been deleted from the abnormal X

chromosome of the wood lemmings[23]

Two explanations may be offered for these opposite results Either there are two populations of wood lemming such that both H-Y$^+$ and H-Y$^-$ X*Y females occur, or, because the authors are using different antisera and different techniques, they are actually studying different antigens

Future prospects

As in many other fields, monoclonal antibodies potentially offer a solution to the many problems of H-Y antigen serology Monoclonal antibodies, which could be freely exchanged between different groups, will undoubtedly form the basis of agreement for the serological definition of the H-Y antigen One such monoclonal antibody has recently been described[25] and attempts have been made to demonstrate identity between the antigen recognized and H-Y defined by cell-mediated cytotoxicity[26], an *in vitro* assay which correlates well with transplantation rejection[27] Other monoclonal antibodies, which apparently recognize products controlled by the Y chromosome, are being studied in several laboratories (ref 28, S Wachtel, personal communication, M Fellous, personal communication) Next year we should know much more about serologically defined antigens controlled by the Y chromosome ☐

Electrostatic interactions in proteins

from Janet M Thornton

PROTEINS are very polar molecules Almost two-thirds of the twenty amino acid side chains are polar and four are charged at neutral *p*H In addition, the arrangement of electrons on the backbone peptide groups gives rise to dipoles which, in the α-helix, align to give a helix macrodipole equivalent to a half unit of charge at each end of the helix (see ref 1 for a review) In analysing protein structure, attention has been focused on the interactions of polar groups with water, a fundamental rule being that polar groups are exposed to solvent, or, where buried, form hydrogen bonds or salt bridges By contrast, interactions between charged groups and dipoles within proteins have received little attention It has been assumed that because all the ionized groups are exposed to water, the electrostatic contribution to free energy will be small, if not zero[2] Two papers[3,4] recently published in *Nature* suggest, however, that the electrostatic interactions between charges and dipoles make important contributions to protein stability and may play a significant part in determining protein structure

Wada and Nakamura[3] consider the relative distribution of positive and negative charges (including the equivalent helix dipole charges) in fourteen proteins For every possible pair of charges e_i, e_j separated by r_{ij} in the protein, they calculate the electrostatic interaction, e_ie_j/r_{ij}, and sum pairwise interactions within a given separation range By comparing the distributions as a function of r for attractive and repulsive interactions they find that there are considerably more attractive, than repulsive, interactions at small separations In other words, a charged group, including the apparent charges of the helix dipole, is on average surrounded by charges of the opposite sign This had already been shown to be true for myoglobin[5] but, surprisingly, it is the first unequivocal proof that charged groups in general are not distributed randomly on the surface of proteins The suggestion is that the charges, including the α-helix dipoles, contribute to the stability of the protein This is an important result because it does not depend on dielectric constant, which is notoriously difficult to evaluate reliably for proteins

The problem of how much energy the charge interactions contribute to the protein is much more difficult Wada and Nakamura evaluate the electrostatic energy of the interactions using the method of Tanford and Kirkwood[6] with the internal dielectric constant set to 4 and the external dielectric constant that of water, at 80 The electrostatic energies they obtain for the fourteen proteins range from +5 kcal mol^{-1} for trypsin to -595 kcal mol^{-1} for liver alcohol dehydrogenase The model does not, however, adequately allow for the different dielectric environments felt by side chains in a complex protein structure Many charged groups are completely exposed to solvent and their electrostatic interactions will be correspondingly decreased Gurd and co-workers[7] have tackled this problem by incorporating a solvent accessibility parameter which reduces electrostatic interactions between exposed groups Their calculation for charge–charge interactions in myoglobin reduces the calculated electrostatic free energy from approximately −400 kcal mol^{-1} to -8 5 kcal mol^{-1} This energy contribution is more reasonable, although the lack of comparable experimental data is a problem

In the hydrophobic interior of the protein electrostatic interactions are much stronger than those between charges exposed to solvent on the surface of the protein Hol *et al*[4] use this argument to suggest that the interactions between the helical dipoles, which are predominantly buried, make a significant contribution to protein stability Their main observation is that a pair of anti-parallel helices is energetically more favourable than a pair of parallel helices, because of the electrostatic interaction between the peptide dipoles The energy difference is evaluated by using the formal charges, assigned to the peptide backbone to mimic the observed dipole moment, and calculating the coulombic interaction e_ie_j/r_{ij} They argue that a macroscopic dielectric constant is inappropriate at the level of atom–atom interactions in the hydrophobic core, and claim their energies are incorrect by no more than a factor of 2 Using this method, the anti-parallel arrangement is more stable, by almost 20 kcal mol^{-1}, than its parallel equivalent They suggest that this electrostatic contribution may have a significant role in determining the observed preference for the anti-parallel arrangement of helices in the all-helical proteins For four of these proteins the dipolar electrostatic stabilizations range from -5 to -23 kcal mol^{-1}

In the α/β proteins with alternating α-helices and β-strands, the α-helices lie approximately parallel, maximizing unfavourable dipolar interactions However, Hol *et al* point out that in parallel β-sheets there is also some alignment of the peptide dipole, which gives a small macrodipole, equivalent to one-fifteenth of a unit of charge at each end of the strand This dipole, together with the fact that the helices are usually tilted because of the twist of the sheet, effectively cancels out the unfavourable interactions

Clearly the helix dipole interactions do contribute to the stability of the anti-parallel helices However, the number of kilocalories involved has yet to be satisfactorily evaluated The figures calculated by Hol *et al* provide the maximum possible stabilization to be derived from dipole interactions Most helices are partially, if not predominantly, exposed, especially in the small all-helical proteins, so presumably some of the peptides will be in contact with solvent However, the closest contacts will be in the hydrophobic core, so although this effect should be considered, perhaps in terms of solvent accessibility, it may not markedly affect the energies

The importance of the electrostatic dipole interactions for determining the anti-parallel alignment of helices and thus protein folding is difficult to assess Many other factors are involved, whose energies may be even more difficult to quantify Topological considerations are one such possibility For every parallel interaction between two sections of chain there must be an anti-parallel connection For example, in the parallel β-barrels, such as in triose phosphate isomerase, the helical connections run approximately anti-parallel to the strands Therefore, we would expect anti-parallel connections to be more common The dipole interactions

---

Janet M Thornton holds an SERC Advanced Fellowship at Birkbeck College, Malet Street, London WC1E 7HX

0028 0836/82/010013 02$01 00

will help stabilize the anti-parallel arrangements, although since the dipoles must be buried to make any significant contribution to energy, they only become important once the hydrophobic core of the protein has been formed

To conclude, both these papers draw our attention to the contribution which charged groups, including the α-helical dipole, make to protein stability The difficulty of assigning an effective dielectric constant, or indeed if a macroscopic dielectric constant is valid for these atom–atom interactions, has yet to be satisfactorily solved and needs urgent attention More experimental data for electrostatic energies or effective dielectric constant, such as that provided by Rees[8], would be of enormous value With high-resolution coordinates now available for many proteins, it should be possible to characterize charge interactions in detail A more exciting possibility is that charged groups, being on the surface of proteins, will be of general importance for recognition between molecules, including protein–DNA interactions Preliminary evidence from the cytochrome *c* peroxidase structure[9] and the assembly of tobacco mosaic virus subunits[10] lends support to this hypothesis Perhaps it is in this context that direct electrostatic interactions may prove most significant ☐

Cell mediated immunity in theileriosis

from F E G Cox

THERE are strong indications that antibody does not play a major role in the immune responses to parasitic protozoa that inhibit nucleated cells but there is some evidence that antibody-independent cell-mediated mechanisms may play a part in protection and recovery Such mechanisms may involve lymphocyte mediated cytolysis (Class I reaction), soluble lymphocyte products (Class II reaction) or natural killer (NK) cells but these mechanisms, although well characterised in mice, are difficult to implicate in the parasitic diseases of man and domesticated animals It is, however, now clear that cell mediated cytolysis plays a major, if not the major, part in the immune response to one of the most important protozoan diseases of cattle, a form of theileriosis known as East Coast Fever

Theileriosis is caused by several species of *Theileria*, of which *T parva*, in Africa, and *T annulata*, which occurs in North Africa, the Mediterranean area and elsewhere, are the most important Considerable mortality results, particularly in calves Theileriosis is a tick-borne disease and cattle become infected when sporozoites are injected by an infected tick The sporozoites enter lymphocytes in which they grow and undergo nuclear division giving rise first to macroschizonts and later microschizonts, the products of which infect red blood cells and thence ticks once again While in the lymphocytes the parasites cause the host cells to undergo rapid division transforming them into what are effectively lymphoblastic cell lines During the stage of macroschizont production there is an accompanying massive destruction of lymphocytes and the infected animal becomes ill and may die

Theileria sporozoites can also transform lymphocytes *in vitro*[1-2] and the availability of such lymphoid cell lines has provided scientists with an ideal opportunity to study cell mediated immune responses against cells of the same genetic type, for uninfected cells can be taken from an animal before infection, transformed and maintained for subsequent study during the course of an infection[3] Scientists at ILRAD (International Laboratory for Research on Animal Disease, Nairobi) have followed *T parva* infections in groups of cattle that died from theileriosis, recovered naturally from the disease or were protected by being infected and treated at the same time with a long acting tetracycline[4-7] In unprotected cattle, by day 14 after infection there was evidence of nonspecific cytotoxic activity against both infected cells and unrelated cells of a mouse tumour line[5] suggesting a mechanism similar to the natural killer (NK) cell phenomenon seem in mice and humans[8] In immunised cattle, on the other hand, small numbers of macroschizonts were detected during days 15-18 after infection and cytolysis was confined to genetically identical infected cells[5-6] An analysis of the mechanisms involved implicated thymus derived lymphocytes as the effector cells[7] and a restriction mechanism whereby effector cells have to recognise both foreign antigens and self antigens simultaneously[6] This is characteristic of class I cell mediated immune responses such as are seen in virally altered cells[8] Although the details of class I reactions and the nature of restriction in cattle remain to be determined all the evidence suggests that in theileriosis the main component of the immune response is the recognition of theilerial antigens on infected cells and the subsequent destruction of these cells by thymus derived lymphocytes

The significance of this work is that it demonstrates the importance of cell mediated immunity in the natural host of an important protozoal disease and also extends the phenomenon of cytolytic restriction to the protozoa Thus theileriosis joins leishmaniasis[9] as examples of intracellular protozoa that are controlled by cell-mediated immune responses, class I in the case of the former and class II in the latter, giving support to the suggestion that the main function of the major histocompatibility complex (MHC) molecules is to guide T lymphocytes to deliver appropriate responses to diverse kinds of infection[10] The diseases of man caused by *Toxoplasma gondii* and *Trypanosoma cruzi*, which are also intracellular, may soon yield up their secrets ☐

Oddities in the initiation of translation

from Peter Model

A report from Kastelein, Remaut, Fiers and van Duin in this issue of *Nature* (p 35) suggests that we may need to modify some of our ideas on how translation is initiated — at least in the particular case of the lysis gene of bacteriophage MS2 Most researchers have concluded that translation is initiated independently at each gene, even in multi-gene operons It may be that mRNA structure will occlude the initiation site at a particular place, and in such instances translation of a preceding gene may be required for effective initiation at some cistrons, but this has generally been viewed as a secondary, complicating phenomenon which obscures the otherwise fundamentally independent nature of the initiation process

Kastelein and his colleagues now present very persuasive evidence that initiation at the lysis gene requires translation of the preceding coat gene and a shift in the reading frame of at least some of the ribosomes into the +1 frame which, in turn, leads them to terminate at an *ochre* codon three nucleotides before the initiating AUG start codon This termination is required for translation of the lysis gene for if the *ochre* codon is removed, translation is abolished If by suitable manipulation of the cloned gene a frame shift is introduced which forces all or most of the ribosomes into the +1 frame, initiation is enhanced Translation of the lysis gene is strictly dependent on active translation at the coat cistron, supplying coat protein in *trans* does not replce this requirement

These data strongly suggest that there is something special about ribosomes that have just terminated at the *ochre* codon that they are in a state which facilitates initiation at sites which would not normally be translational initiators It is not yet clear what this special property might be, it could be a special state of the ribosome, or retention of the 30S ribosomal subunit on the RNA after termination of synthesis It has been noted previously that termination at various chain-terminating codons within genes facilitates re-initiation at specific distal sites, although here too the mechanism (s) remains undefined

These observations would at first glance seem to run counter to recent *in vitro* results from Kaji's laboratory Ryoji, Berland and Kaji (*Proc natn Acad Sci U S A* **78**, 5973, 1981) report that when they removed the ribosome release factor from *Escherichia coli* ribosomes and then supplied an RNA containing an amber mutation as template, these release factor-depleted ribosomes synthesize two fragments of the relevant protein One starts at the usual initiating methionine and stops at the *amber* codon, while the other starts at the codon immediately after the *amber* codon and ends at the normal C terminus of the protein Ryoji *et al* argue that this result excludes 'special conformation' or 'sterile pass' models of ribosome initiation following termination They conclude that when a ribosome terminates it either dissociates completely or else starts again at the very next codon The characterization of the products of the release factor-depleted ribosomes was careful and thorough, the question that remains is whether there is any relationship between the behaviour of these release factor-depleted ribosomes *in vitro* and the phenomenon described *in vivo* by Kastelein *et al* Kaji and co-workers have carefully characterized an experimental system of their own design which may shed light on the mechanism of termination/initiation, but which may not be relevant to the genesis of the phenomena described by Kastelein *et al* They propose on the basis of their rather specific *in vitro* work that there are only two possible fates for a ribosome when it reaches a stop codon release with no special state, or retention on the mRNA, in which case it will simply start protein synthesis at the next codon The *in vivo* studies from Van Duin's lab suggest that other possibilities are available, and have been exploited by the RNA phages ☐

Magnetic messages from the Earth's core

from David Gubbins

OVER the centuries the Earth's magnetic field has shown marked changes This 'secular' variation, known even to the early navigators, almost certainly originates in the core of the Earth and provides one of the few sources of information about the physical processes that occur there Shorter-duration magnetic field changes can also be recorded (on a time scale of a few years) but are hard to interpret because of the difficulty of separating changes in intrinsic magnetism from the short-term influences of the Sun and the upper atmosphere The major problem at present is how best to make use of the information provided by the secular changes

Alldredge[1] has recently proposed a model of intrinsic field fluctuation The fluctuation propagates up through the Earth's mantle, which is a rather poor conductor of electricity, and his model produces surprisingly sharp changes at the surface In consequence, if we are to decipher these signals from the interior of the Earth, we must measure and study even shorter-period wavelength variations than hitherto This important conclusion stands quite independent of Alldredge's specialized and rather arbitrary models, and it is timely coming soon after the MAGSAT mission which has provided the most complete and accurate magnetic chart we have ever had[2] Unfortunately MAGSAT only flew for a few months, not long enough to chart the secular changes with any accuracy At present the best data for this purpose come from permanent magnetic observatories A second MAGSAT, flown about five years hence, would yield vastly more accurate and complete information

The liquid core of the Earth extends out to about one-half the radius, is made mainly of iron, has a viscosity rather like water and is a better electrical conductor than copper The mobility of this liquid causes the magnetic field to change through electromagnetic induction The phenomenon occurs very rapidly in geological terms, the fluid moving at a rate of a few millimetres per second

Secular change was much discussed, even in the earliest days of geophysics Halley, like others of his time, believed the magnetic field to be due to magnetized rocks. The secular changes could not be due to motion of rocks near the surface because the required speed would be too great, so Halley proposed that the interior of the Earth was hollow, and that an inner, magnetized sphere was rotating westwards, generating the slow westward drift of the magnetic field pattern[3] This remarkable theory came 200 years before the discovery of a liquid core by seismology With modern ideas of a 'hot' Earth and a liquid iron core we can now deduce a value of the core radius from magnetic measurements alone[4]

The big snag is that we do not yet fully understand the dynamo theory of the origin of the magnetic field itself, and therefore there are no really satisfactory models of the field changes in the core Alldredge uses a very common mathematical device representation by a distribution of dipole sources These dipoles have no physical meaning whatever, unless one wants to adhere to Halley's ideas of moving magnetized rocks and represent them by little bar magnets in the core, which is not the intention Granted a source of field,

there is still a serious theoretical difficulty in propagating magnetic disturbances through a liquid conductor, and in order to make progress Alldredge has been forced into treating the core as a solid, thus substituting the theory of electromagnetic propagation for the much more difficult hydromagnetic theory But the physics of the two situations are very different a liquid, for example, allows propagation of a variety of waves which are impossible in a solid, and these waves will allow magnetic variations to propagate, when in a solid they would be screened due to electrical conduction In fact the core possesses a whole spectrum of free hydromagnetic oscillations[5].

Although hydromagnetic theory is difficult, it is possible to describe the induction process in the core by Maxwell's laws On the time scale over which we have observations, say 10–20 years, the electrical conductivity of the core is so high that resistance effects can be ignored This assertion can, and has been, tested against observation One might hope, therefore, to infer the motion of the fluid at the top of the core from magnetic observations, but this is not possible[6] unless we can confidently make further assumptions about the forces driving the flow However, recent work has shown how to find some general features of the core flow even though a detailed map of the motions may be beyond our grasp For example, upwelling of liquid from deep inside the core can be measured at points where the magnetic field at the core attains a maximum of minimum vertical component Surprisingly, the upwelling is very small at these locations[7], suggesting that the liquid is not convecting strongly, at least near its upper surface

This and other recent proposals[8] suffer from the poor quality of available data Field changes are monitored at only a few Southern Hemisphere sites The field must be projected down onto the core surface before it can be interpreted — a procedure well understood in principle but inherently unstable when the observations are inaccurate or sparse Two recent models of the secular change for 1965 agree quite well at the surface of the Earth but differ by factors of up to two or three at the core The differences are due in part to the methods that are used in computing the models from the observations, and not all to inadequate data, so that while we wait for another MAGSAT there is still hope for improvements in models of past years by new analytical methods. □

Animal disease and conservation

from Geoffrey R Smith

WHEN the material interests of man and the well-being of wild animals are considered side by side, real conflicts of interest emerge Advances in human medicine lead to the growth of population, an increased demand for land and a corresponding loss in wildlife habitat Environmental pollution is a well recognized side effect of industrial development Less well understood by many is the threat to wild animals from infectious disease Fatal or incapacitating infections may be introduced by domestic animals, and there can also be times when the destruction of wildlife becomes necessary to protect man and domestic animals from disease These matters were considered at a recent symposium* held at the Zoological Society, under the general chairmanship of Sir Andrew Huxley, PRS.

From 1889 to 1898 rinderpest swept from North-east Africa to the west coast and Cape of Good Hope in a 'virgin-ground' panzootic that produced catastrophic losses in cattle and many wild ungulate species (W Plowright, ARC Institute for Research on Animal Diseases) The disease was eliminated from southern Africa, but a focus of mild permanent infection later became established in the Serengeti region Rinderpest disappeared from both cattle and game in that region in about 1964, after cattle had been treated with attenuated tissue-culture vaccine for several years Between 1961 and 1971 the number of buffaloes and wildebeest in the Serengeti more than doubled, probably largely because the young no longer died from rinderpest There are now 1–15 million highly susceptible wild ungulates in the Serengeti. Once again they are under threat of invasion by rinderpest from the north-east Plans need to be made now to meet this threat

Although antigenically very similar, rabies virus strains from vampire bats in South America and foxes in western Europe have characteristic features detectable by monoclonal antibodies Bats and foxes are sometimes killed as a means of controlling rabies When fox population density falls below 0 3 per km^2 the disease disappears An alternative strategy, still experimental but possibly of great significance, is the use of attenuated virus, concealed in chicken-head baits, to immunize foxes The oral-vaccine virus multiplies in the tonsil and so far shows no sign of reversion to virulence (F Steck, Vet.-Bakteriologisches Institut, University of Bern)

The role of animal infections in the origin and spread of human influenza pandemics is still the subject of much speculation (M Kaplan, Pugwash Conferences on Science and World Affairs, Geneva) Inter-species infections can and do occur on occasion, apparently when mutations and recombinations take place The segmental mode of replication of influenza virus favours recombinative encounters between human and animal strains Wild birds, in which infection is mainly intestinal and symptomless, constitute an ineradicable reservoir of the everchanging virus — a reservoir that is a permanent potential threat to man and other animals Recent observations on whales, seals and terns show that influenza in wildlife is not always subclinical, and that high mortality can occur

Botulism kills millions of waterfowl annually on lakes and marshes throughout the world, and no radical control methods are known (G R Smith, Institute of Zoology, The Zoological Society of London) Mud from certain localities, such as the Camargue, inhibits the growth of *Clostridium botulinum* Our knowledge of the inhibitory mechanisms is incomplete, and a deeper understanding might give some hope for control As an adjunct to wetland management, surveys for the causative organism are advocated to distinguish between areas of high and low risk

The evidence that bovine tuberculosis infection is transmitted from badgers to cattle is irrefutable, and the impossibility of separating the two species physically or protecting them adequately by vaccination has necessitated the policy of gassing badgers in the south-west of England (Sir William M Henderson) While research on the problem continues, the present control policy cannot be abandoned without causing suffering for us all — human beings, cattle and, not least, badgers.

It is impossible to generalize about the part played by disease in the control of numbers of wild animals in comparison with that due to water and food supply But what the symposium made absolutely clear is that the whole field of animal disease is now of major importance The subject overlaps at almost every point with that of disease in man and in domesticated animals and offers a great intellectual challenge to the research worker □

Ion-supported tori and the origin of radio jets

M. J. Rees*, M. C. Begelman*‡, R. D. Blandford† & E. S. Phinney*

* Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK
† Theoretical Astrophysics, California Institute of Technology, Pasadena, California 91125, USA
‡ Department of Astronomy, University of California, Berkeley, California 94720, USA

While apparently supplying tremendous power to their extended radio-emitting regions, the nuclei of most radio galaxies emit little detectable radiation. It is proposed that at the centre of each is a spinning black hole surrounded by a torus of gas too hot and tenuous to radiate efficiently. The torus anchors magnetic fields which extract rotational energy from the hole in the form of two collimated beams of relativistic particles and fields. These in turn drive the observed radio jets and hot spots. A large supply of accreting gas is thus unnecessary and radio galaxies may be interpreted as starved quasars.

ALL extended radio sources seem to be associated with elliptical galaxies or quasars, and the evidence[1] suggests that quasars too are located in ellipticals. As the present number-density of dead quasars is comparable with that of elliptical galaxies[2,3], it is reasonable to suppose that radio sources are powered by $\sim 10^8 M_\odot$ black holes[3] left over from a quasar phase. A long-standing problem in the theory of active galactic nuclei has been that of finding a supply of nuclear gas adequate to 'feed the monster'. Stars in the galactic nucleus cannot provide more than $\sim 10^{-3} M_\odot \text{yr}^{-1}$, unless conditions are so extreme that stellar collisions dominate the evolution[4]. Gas originating further out must dispose of substantial angular momentum to enter the nucleus[5,6], and it must do so before succumbing to galactic winds or star formation.

The observational evidence is less ambiguous: radio sources almost certainly do have low fuelling rates. Low-luminosity double-jet radio sources of the sort being mapped with the VLA generally have no detectable nuclear emission in the optical or X-ray bands; of the more powerful double hot spot radio sources, only a few (such as 3C390.3 with $\sim 2 \times 10^{44} \text{erg s}^{-1}$ in both optical and X-ray bands[7], and Cygnus A with $\sim 2 \times 10^{43} \text{erg s}^{-1}$ in optical continuum[8]) have nuclear luminosities above $10^{42} \text{erg s}^{-1} = 10^{-4} M_8^{-1} L_{\text{Edd}}$ (refs 9, 10). They cannot be produced by any process requiring super-Eddington luminosity, unless the hole mass is very small. This it cannot be because (even aside from the progenitor argument) some low-luminosity radio sources have giant ($\sim$Mpc) extensions with minimum energies[11] of up to $2 \times 10^{60} \text{erg s}^{-1} = 10^6 M_\odot c^2$. Even if we make optimistic estimates of the efficiency of the central 'engine' and of the likely efficiency with which power emitted from the nucleus can accelerate relativistic electrons in the radio lobes, we must conclude that a mass of at least 10^7–$10^8 M_\odot$ is involved (in computing the powers and energies above, we have used a Hubble constant of $H_0 = 50 \text{ km s}^{-1} \text{Mpc}^{-1}$).

Recent VLBI observations[12–17] have corroborated the view that the jets which power extragalactic sources are collimated on scales $\leqslant 1$ pc. These observations reveal small-scale structure which is generally aligned with larger-scale structure. Misalignments of up to ~45°, which have been found in the core-dominated superluminal sources, are probably caused by viewing a slightly curved jet along an almost parallel line of sight. In the case of the cores of extended radio sources, however, the alignment is fairly good. Any mechanism which purports to explain them must, therefore, be capable of producing collimated jets of at least trans-relativistic velocities while radiating as waste heat much less than an Eddington luminosity. Furthermore, it must, at least in some more extreme sources, put orders of magnitude more power into the jet than escapes as (detectable) radiation from the nucleus. These constraints rule out the class of models involving thick disks supported by radiation pressure[18–25].

Sub-critical accretion

To understand radio sources, we should therefore study accretion at very low rates, $\dot{M} \ll \dot{M}_{\text{Edd}} \equiv L_{\text{Edd}}/c^2$. Accreted gas should carry with it some magnetic flux, and shearing motions will maintain the magnetic field energy $B^2/8\pi$ at a significant fraction β^{-1} of the pressure P. The Larmor radius is then, for the applications which interest us, about 10 orders of magnitude smaller than the scale of the flow. Ordinary 'molecular' viscosity will consequently be suppressed, and magnetic (or possibly turbulent) viscosity will probably govern the shear stress. The viscous stress may be written as αP, where estimates of magnetic viscosity suggest $\alpha \geqslant 0.01$ (ref 26). Although this estimate is uncertain, there is no reason why α should diminish as $\dot{M}$ falls: if α is fixed, the torque per unit mass will be independent of $\dot{M}$ (except insofar as the disk structure depends on $\dot{M}$). Thus the inflow time in a disk of half-thickness $h(r)$ around a hole of gravitational radius $r_g = GM/c^2$,

$$t_i = \alpha^{-1}\left(\frac{r}{r_g}\right)^{3/2}\left(\frac{h}{r}\right)^{-2}\left(\frac{r_g}{c}\right) \qquad (1)$$

does not depend explicitly on density. (See refs 27–29 for the standard theory of thin disks with $h \ll r$.) The cooling time, on the other hand, is inversely proportional to the density.

The thickness of the disk depends on how fast it can radiate (or otherwise dispose of, say by a wind) the binding energy liberated by viscous stresses. The major cooling mechanisms available to the accreting matter are illustrated in Fig. 1. Depending on initial conditions and external perturbations the matter may find itself in any of several temperature states. In fact, for $10^{-7} \leqslant (\dot{M}/\dot{M}_{\text{Edd}})\alpha^{-2} \leqslant 50$ there are two self-consistent solutions to the fluid and radiation equations.

One is a thin, dense disk that remains at $\sim 10^4$ K. If matter with well defined angular momentum is fed in steadily (with high angular momentum) at a large radius, and there are no traumatic perturbations, this cold disk should be selected. These disks are, however, subject to instabilities[5,30,31], and if heated up and thickened, they will thereafter be unable to radiate the energy dissipated by viscous stresses, and will inflate to become pressure-supported tori with vortices along the rotation axis (see Fig. 2). The hot torus solution will also be selected if cool matter is preheated by high-frequency non-thermal radiation (for example, from a jet), or if the gas is supplied hot (for example by colliding stellar winds[6] or by tidal disruption of stars[32,33]). Both of these latter examples lead to flows which join naturally onto the ones described here.

0028-0836/82/010017—05$01.00

For an optically thin disk to radiate by bremsstrahlung, the energy dissipated between r and $r/2$, the accretion rate must satisfy

$$m = M/M_{\mathrm{Edd}} \geqslant \alpha_{\mathrm{f}}^{-1}\left(\frac{m_{\mathrm{p}}}{m_{\mathrm{e}}}\,\frac{r_{\mathrm{g}}}{r}\right)^{1/2}\alpha^{2}\left(\frac{h}{r}\right)^{2}, \quad r > \left(\frac{h}{r}\right)^{2}\left(\frac{m_{\mathrm{p}}}{m_{\mathrm{e}}}\right)r_{\mathrm{g}} \qquad (2a)$$

$$m \geqslant \alpha_{\mathrm{f}}^{-1}\alpha^{2}\left(\frac{h}{r}\right)^{3}(\log\gamma_{\mathrm{re}})^{-1}, \quad r < \left(\frac{h}{r}\right)^{2}\left(\frac{m_{\mathrm{p}}}{m_{\mathrm{e}}}\right)r_{\mathrm{g}} \qquad (2b)$$

where $\alpha_{\mathrm{f}} = 1/137$ is the fine structure constant and $\gamma_{\mathrm{re}} = 3\,\mathrm{k}T_{\mathrm{e}}/m_{\mathrm{e}}c^{2}$ Hence at the low accretion rates of interest ($m \simeq 10^{-4}$), a disk once heated to $T \approx T_{\mathrm{virial}} = (m_{\mathrm{p}}c^{2}/3k)(r_{\mathrm{g}}/r)$ will be unable to cool through bremsstrahlung and must remain pressure-supported with $h \approx r$

As the gas moves in, however, it will shear and amplify any seed magnetic field until $B^{2}/8\pi \simeq P_{\mathrm{gas}}$, and the fields begins to rise buoyantly out of the disk (moving perpendicular to the plane of a thin disk, towards the vortex funnel in a thick torus) We thus expect the ratio β to be self-limiting at $\beta \simeq 1$, although β may be $\ll 1$ in a corona if the latter is threaded by field lines anchored to interior (high-pressure) parts of the disk, as in the solar atmosphere The corona may also join onto a wind (M C B *et al* in preparation, and ref 34) This magnetic field provides the torus with a new cooling mechanism for $r < (m_{\mathrm{p}}/m_{\mathrm{e}})r_{\mathrm{g}}$, electrons at the virial temperature of the ions would be relativistic, and each would radiate an energy

$$\Delta E_{\mathrm{r}} \approx kT_{\mathrm{i}}\left(\frac{50r_{\mathrm{g}}}{r}\right)^{31/4} m_{-4}^{1/2}\alpha_{-2}^{-3/2}\beta^{-3/2}M_{8}^{-1/2} \qquad (3)$$

by optically thick synchrotron radiation as it spiralled in from r to $r/2$ (where $m_{-4} = 10^{4}\,m$ and $\alpha_{-2} = 10^{2}\alpha$) The actual cooling rate is considerably higher for

$$r < r_{\mathrm{comp}} \equiv \left(\frac{m_{\mathrm{p}}}{m_{\mathrm{e}}}\right)^{4/5}(m\alpha^{-1})^{2/5} = 65\,m_{-4}^{2/5}\,\alpha_{-2}^{-2/5} \qquad (4)$$

since then the dominant cooling is due to Compton scattering of the synchrotron photons (Fig 1) Thus if the electrons and ions are kept in energy equipartition, a thick torus will cool and deflate to a thin disk for $r \leqslant 50r_{\mathrm{g}}$

The torus will be 'collisionless' inside some large radius (typically ~2,000 r_{g}, but defined more precisely below), in the sense that through two-body collisions alone protons at temperature T_{p} give less than half their energy to electrons (with $T_{\mathrm{e}} < T_{\mathrm{p}}$) on the inflow time scale, if

$$m < \left(\frac{m_{\mathrm{p}}}{m_{\mathrm{e}}}\right)(\ln\Lambda)^{-1}\alpha^{2}\left(\frac{m_{\mathrm{p}}}{m_{\mathrm{e}}}\,\frac{r_{\mathrm{g}}}{r}\,\frac{T_{\mathrm{e}}}{T_{\mathrm{p}}}\right)^{3/2}$$

$$\approx 50\alpha^{2}\left(\left(\frac{2{,}000r_{\mathrm{g}}}{r}\right)\left(\frac{T_{\mathrm{e}}}{T_{\mathrm{p}}}\right)\right)^{3/2} \quad kT_{\mathrm{e}} < \tfrac{2}{3}m_{\mathrm{e}}c^{2} \qquad (5a)$$

$$m < \left(\frac{m_{\mathrm{p}}}{m_{\mathrm{e}}}\right)\left(\frac{\gamma_{\mathrm{re}}}{\ln\Lambda}\right)\alpha^{2} = 50\gamma_{\mathrm{re}}\alpha^{2} \quad kT_{\mathrm{e}} > \tfrac{2}{3}m_{\mathrm{e}}c^{2} \qquad (5b)$$

In these conditions, collective plasma phenomena will determine the particle distribution functions, the radiative efficiency, and thus the pressure and shape of the whole torus/disk In most of what follows we assume that collective processes are unable to transfer more than half the proton's kinetic energy to the electrons [which would in turn quickly radiate it compare with equation (3)] Given the complexity of the plasma physics and the uncertainties in accretion theory, it may be a long time before this assumption can be checked If the collective transfer can take place, the structure is similar to that already familiar from results at high accretion rates If it cannot, one consequence, as already realized in the context of accretion disks around stellar-mass black holes[35 36], is a 'two-temperature' flow

Two-temperature tori

Consider an accretion flow where equation (5) is satisfied for $r < r_{\mathrm{D}}$, and assume that the protons and electrons are then

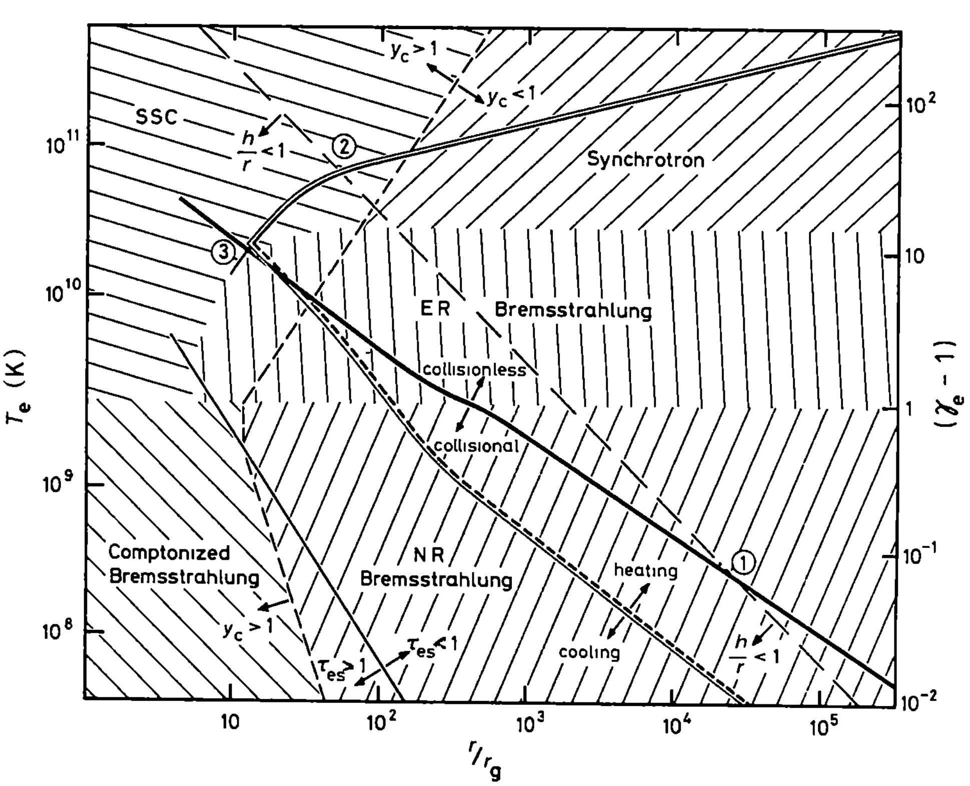

Fig. 1 The dominant local cooling mechanisms for a representative ($\alpha = 10^{-2}$, $\beta = 1$) low-accretion rate ($m \equiv M/M_{\mathrm{Edd}} = 10^{-4}$) flow about a central mass of $10^{8}M_{\odot}$, as a function of distance (measured in units of $r_{\mathrm{g}} \equiv GM/c^{2}$) from the central mass and electron temperature (which also parametrizes disk thickness, a scale of electron kinetic energy in units of $m_{\mathrm{e}}c^{2}$ is at right) We have assumed electron and ion temperature to be everywhere equal, although Coulomb collisions are insufficient to maintain equipartition for disk states above the heavy solid line In the C-shaped region to the left of the double lines the cooling rate exceeds the rate of viscous heating and the disk will collapse To the right of the double lines the rate of heating exceeds that of cooling and the disk will thicken (states above the $h/r = 1$ line are unphysical in the absence of external pressure forces) SSC denotes synchrotron self-Compton cooling ('the Compton catastrophe'), τ_{es} is the optical depth to Thomson scattering

$$y_{\mathrm{e}} = \begin{array}{ll} \tfrac{8}{3}(\gamma_{\mathrm{e}}-1)\tau_{\mathrm{es}}(\tau_{\mathrm{es}}+1) & \text{for } \gamma_{\mathrm{e}}-1 \ll 1 \\ \tfrac{16}{9}\gamma_{\mathrm{e}}^{2}\tau_{\mathrm{es}}(\tau_{\mathrm{es}}+1) & \text{for } \gamma_{\mathrm{e}}-1 > 1 \end{array}$$

is the Compton y-parameter Not included are induced Compton cooling, non-local Compton cooling/heating and losses to winds The disk is everywhere supported by gas pressure Radiation pressure is only important in the inner parts of cold, thin disks for $m > 10^{-3}$ If, for $r \leqslant 10^{7}r_{\mathrm{g}} \simeq 100\,M_{8}$ pc, the disk is heated to a temperature above that at which bremsstrahlung cooling becomes inefficient (double dashed line) it will thicken to a torus, $h \sim r$ For $r < r_{\mathrm{D}} = 2\times10^{4}r_{\mathrm{g}}$ (point 1), Coulomb collisions cannot maintain equipartition If plasma processes take over this job, the disk will begin to cool by SSC at $r \simeq 50r_{\mathrm{g}}$ (point 2) and will gradually thin to $(h/r) \sim \frac{1}{4}$ at $r = 10r_{\mathrm{g}}$, at which point (3) bremsstrahlung will rapidly cool it to a new equilibrium at $T \sim 10^{4}$ K and $(h/r) \sim 10^{-4}$ where it radiates as a black body (optically thick bremsstrahlung and line cooling just balance viscous heating) If, as assumed here, equipartition cannot be maintained, the electrons continue to cool (Fig 3) inside $r = r_{\mathrm{D}}$ (point 1) but the ions remain at the virial temperature The torus will thus remain thick, with the structure shown in Fig 2 indeed thermally decoupled from each other Equation (2) shows that, for $m_{-4} \simeq 1$, the thick ($h \simeq r$) torus is a self-consistent solution even for $r \gg r_R = 2{,}000 r_g$ (see Fig 1) At $r_D \gtrsim r_R$, electrons and ions will decouple, but as neither can cool, they may remain at the same temperature For $r < r_R$, the electrons become relativistic If the heating of both species is adiabatic, then $T_p \propto n^{2/3}$ while $T_e \propto n^{1/3}$, so the ions are preferentially heated Shock heating may likewise favour the ions, as isotropization of the bulk flow velocities will give to each species a thermal energy proportional to its mass Fermi acceleration processes will amplify any temperature difference once it exists Thus the electrons are granted little of the ions' energy, despite their ability to radiate it [equation (3)] The ions remain at the virial temperature, and the two-temperature torus remains thick even inside $r \simeq 50 r_g$ [equations (3) and (4)]

If the torus surrounds a spinning black hole, the Lense–Thirring effect can enforce axisymmetry with respect to the hole's spin axis[37] out to a radius $\sim \alpha^{-2/3}(J/J_{max})^{2/3} r_g$, where J is the hole's angular momentum and $J_{max} = M r_g c$ is the maximum value allowed by the Kerr metric We would expect the holes to have been spun up to $J \approx J_{max}$ during their previous quasar phase[38 39] There may be misalignment outside this radius if the gas is not supplied in the equatorial plane of the hole The isotherms within the torus can then be calculated in the same way as for radiation-supported tori[18 19,22] If the pressure support is due primarily to non-relativistic ions, then the effective specific heat ratio will be about 5/3 If α is independent of radius, then $n \propto r^{-3/2}$, and most of the mass of the torus resides at large radii If both these conditions are fulfilled, then the ions are roughly isentropic

The contours of Fig 2 have been computed by this procedure The results are subject to the same uncertainties as those for radiation-supported tori problems with self-consistency in viscosity (R D.B and M Jarozyński, in preparation), and the absence of a formalism for properly matching one of these inner solutions onto a flow field specified at large radii Magnetic fields will modify the simple structure shown However, essential features, such as the characteristic vortex funnel, which becomes parabolic in the limit of a flow with constant specific angular momentum l and is less collimated than parabolic for a flow with l increasing outwards, are unlikely to be changed (Flows for which l decreases outwards are argued to be unstable, note, however, that l must be constant along the surface if there is no poloidal circulation and we insist that the surfaces have zero energy-at-infinity) In this 'zone of non-stationarity', matter cannot have enough angular momentum to achieve near-equilibrium between centrifugal force, pressure and gravity A fluid flow in the funnel must either fall straight into the hole, or have enough enthalpy to leave the region rapidly Hydromagnetic effects[40] or flares (compare with previous remarks about buoyant fields) on the funnel walls will inject into it particles of positive energy-at-infinity The liberated power will escape along the two funnels, leading to a pair of inertially collimated jets carrying some fraction of $Mc^2 = 10^{42}\, m_{-4} M_8$ erg s^{-1} This may be enough to explain the low-luminosity double-jet radio sources

Electromagnetic extraction of the hole's rotational energy

If the central black hole is near-maximally rotating ($J \simeq J_{max}$), a much greater supply of free energy is available the rotational energy of the hole (up to 29% of Mc^2 for $J = J_{max}$) If an ordered electromagnetic field can be supported around the hole, then it can put particles (which may in fact be inside the horizon if the field threads the latter) systematically on negative energy orbits The negative energy swallowed by the hole appears as positive energy in the external fields and thus drives away from the hole a Poynting flux of luminosity[41–43]

$$L_{EM} \lesssim B_{pH}^2\, r_g^2 (J/J_{max})^2 c \qquad (6)$$

where B_{pH} is the poloidal field in the flux tube that intersects the hole s horizon If $J \simeq J_{max}$, then this power $\lesssim 10^{44} M_8 \alpha_{-2}^{-1} m_{-4} \beta_{pH}^{-1}$ erg s^{-1} (where β_{pH} = (maximum gas pressure in torus)/($B_{pH}^2/8\pi$)) can exceed by $\gtrsim \alpha^{-1}$ the rate of liberation of binding energy by the accreting matter The torus will be able to confine and initially collimate the extracted power, as the associated radiation (or ram) pressure will be less than the gas pressure in the torus if

$$Mc^2/4\alpha > L_{EM} \lesssim Mc^2/(20\alpha\beta_{pH}) \quad (J/J_{max})^2 \qquad (7)$$

Both these inequalities are nearly always satisfied since $\beta_{pH} \gtrsim 1$

To extract power predominantly from the hole, we must have $\beta_{pH} \simeq 1$ and $\alpha \ll 1$ Is this consistent with a physically attainable disk structure? One might naively suppose that the poloidal field could be generated by currents distributed through the torus, and thus be an extension of an ordered field structure within it But if this were the case, the internal fields would transport energy and angular momentum outwards so efficiently that $\alpha \simeq 1$ and L_{EM} would be $\lesssim Mc^2$ Furthermore, in the presence of a magnetosphere any current loop in keplerian rotation around a central mass loses energy from its outer light cylinder at a rate (~vacuum magnetic dipole power) $\simeq (J_{max}/J)^2$ times the rate at

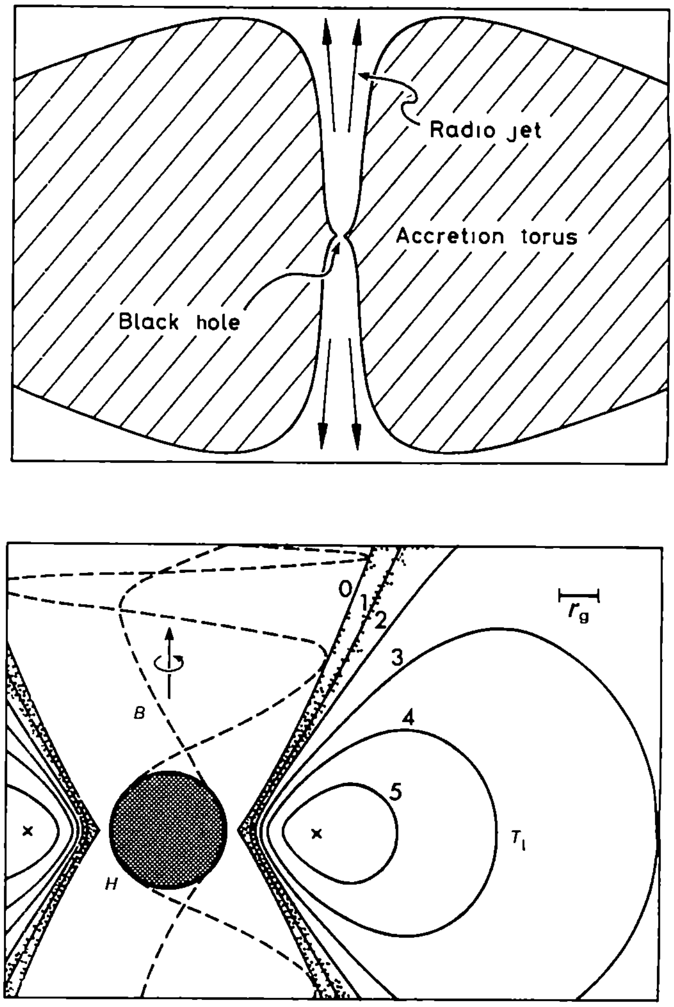

Fig. 2 An accretion torus supported by ion pressure surrounds a spinning black hole The torus defines a pair of funnels capable of collimating a relativistic hydromagnetic flow which ultimately forms the observed radio jets The enlargement shows the inner regions of the torus and displays contours of ion temperature in units of 10^{11} K (solid lines) These have been calculated assuming that the ions are an isentropic gas with constant specific angular momentum and that the hole (horizon H) has $J = 0\ 9\ J_{max}$ (see ref 19) The outer isotherm is also the surface of zero binding energy The dashed lines represent the magnetic field lines in the configuration discussed in the text A poloidal current flows in the funnel Large toroidal currents and the return poloidal currents flow in a thin surface layer (stippled)

which it could extract power were the central mass a black hole of angular momentum J If the current loop runs in an accretion disk, the missing power must be provided by the liberation of binding energy, which again implies $L_{EM} \lesssim Mc^2$ (compare with the thin-disk solution of Blandford and Znajek[42] in which $L_{EM} \simeq 0\ 3\ (J/J_{max})^2\ L_{disk}$)

To understand how a torus could avoid all this energy transport and loss, it is helpful to consider the time evolution of a perfectly conducting torus with a very weak ($\beta_p \gg 1$) magnetic field piercing it at large radii (It may also have internally closed field loops of arbitrary strength) This weak field is convected in with the flow, and by applying Faraday's law to a sufficiently large loop encircling the rotation axis, we find that the magnetic flux through the funnel increases as we carry field in, even though the field lines are causally disconnected from the matter in which they were frozen after the latter has crossed the horizon[43] If the torus behaves like a perfect conductor, it will exclude this increasing external flux by developing surface currents The field and surface currents will increase (perhaps shutting off the accretion altogether) until either some massive plasma-field interchange instability leads to an explosive energy release or, more likely, dissipation in the surface layer destroys piercing field as fast as it is convected in The structure of such a torus is rather different from that of the field-free torus the $\mathbf{J}_T \times \mathbf{B}_p$ force across the surface layer (funnel boundary) must be balanced by a gradient of gas pressure, so that at its base $P_{gas} \simeq B_{pH}^2/8\pi$ If we want $\beta_{pH} \simeq 1$, most of the drop of gas pressure must occur in the surface layer, the inner parts of the torus being at roughly constant pressure

We can imagine the following self-consistent solution for a torus with a jet (Fig 2) toroidal currents in the thin surface layer of the vortex funnel produce a poloidal field which is torqued by the hole, driving an outgoing Poynting flux This will soon become plasma-loaded, toroidal fields will begin to dominate, causing self-collimation[34 44 45] The return poloidal current must also flow in the thin surface layer, pulling material from it into the funnel, but leaving the bulk of the torus unaffected The only forces from the jet transmitted to the body of the torus are those due to the poloidal field (transmitted by the gas pressure in the subcutis), whose pressure drops as (area of funnel)$^{-2}$ and which thus has less effect on the structure of the torus the further out we go Simple solutions ignoring the jet can therefore correctly model the torus, while the jet may collimate itself on the paraboloidal field lines thus defined without exerting much modifying force

The above discussion shows how a torus supported by ion pressure, with a low accretion rate $\dot{M}$ can catalyse the extraction of a hole's spin energy at a rate $\gtrsim \dot{M}c^2$ Moreover, we show below that the luminosity from the torus itself may be $\ll \dot{M}c^2$ Thus if the meagre losses from the torus can be replaced by energy and angular momentum extracted from the hole, there need be no accretion only the inertia of the torus, and the currents in it are needed to confine the magnetic fields that tap the hole's energy

Losses and radiation from the torus

The total power dissipated in the surface layer of thickness s is $\sim (s/r_g) L_{EM} \ll L_{EM}$ Moreover, as only a very weak field need penetrate the torus, transport and losses from the outer light cylinder may also be negligible The radiation emitted by the body of an ion-supported torus will be primarily non-thermal, its magnitude depends sensitively on the efficiency of electron acceleration The torus will generally be optically thin to Thomson scattering, with a total optical depth along a line of sight in the equatorial plane, from the hole to infinity, of $\sim \dot{m}\alpha^{-1}$ Incoherent cyclotron and synchrotron radiation will be self-absorbed (The conditions envisaged resemble those of a so-called 'plasma turbulent reactor'[46], so that a power law spectrum may be set up) The torus will, however, be optically thin to γ radiation produced by relativistic electron bremsstrahlung, and to inverse Compton radiation at frequencies above 10^{13} Hz The relevant relaxation times that go into fixing the electron temperature are plotted in Fig 3, which shows that the electrons will be able to radiate efficiently from the inner part of the torus only if their temperatures exceed 10^{10} K At higher temperatures the power radiated increases very rapidly with temperature the optically thick synchrotron losses vary as T_e^7, and the dependence on T_e is steepened further because repeated Compton scattering of synchrotron photons up to the γ-ray band dominates when $\gamma_e^2 \tau_{es} > 1$ However, as long as equation (5) is satisfied, the electrons can radiate only the small fraction of the total energy which they can drain from the ions (or derive from adiabatic heating) and the ion-supported torus will not collapse For the parameter range of interest, the radiation will be in the far IR or the γ-ray region of the spectrum, according as $\dot{m} \lessgtr 10^{-5} \alpha_{-2}^{3/5} \beta^{-3/5} M_8^{-1/5}$ We cannot exclude the possibility that coherent radiation from fields ~ 100 G may be important But, although this might seem relevant to the phenomenon of low-frequency radio variability[47] it would be subject to electron synchrotron absorption and induced Compton scattering[48 49]

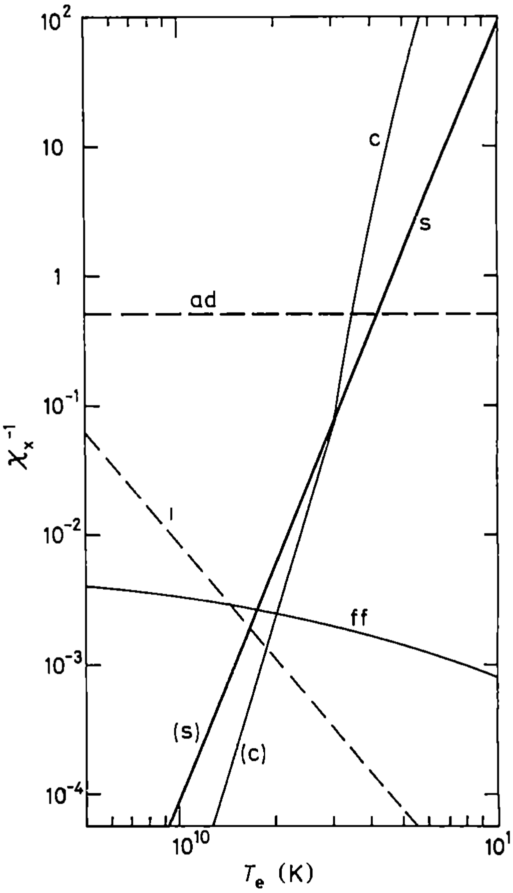

Fig 3 Dimensionless electron relaxation rates χ_x^{-1} as a function of the electron temperature T_e χ_x^{-1} is related to the heating or cooling rate per unit volume ε_x by

$$\chi_x^{-1} = \frac{\varepsilon_x}{3n^2kT_e\sigma_T c}$$

The lines are drawn for $\alpha = 10^{-2}$, $\beta = 8\pi nkT_i/B^2 = 1$, $\dot{m} \equiv \dot{M}/\dot{M}_{Edd} = 10^{-4}$, $r_* = r/r_g = 5$, and $M = 10^8 M_\odot$ The relaxation rates with appropriate scalings are compressional heating, $\chi_{ad}^{-1} \propto \alpha^2 \dot{m}^{-1}$, collisional heating by ions, $\chi_i^{-1} \propto r_*^{-1}$, optically thick synchrotron cooling, $\chi_s^{-1} \propto \alpha^{1/2}\beta^{-3/2} r_*^{-7/4} \dot{m}^{-1/2} M^{-1/2}$, optically thin Compton cooling, $\chi_c^{-1} \propto \alpha^{-2}\beta^{-1} r_*^{-3\ 25} \dot{m}^2$, and relativistic electron bremsstrahlung χ_{ff}^{-1} (no scaling) Self-absorption of the Compton radiation, double-Compton and pion cooling and pair production are unimportant for the range of densities and temperatures under consideration The virial temperature of the ions is 7×10^{11} K $(r_*/5)^{-1}$ (see also Fig 2), while in the absence of losses, compressional heating of electrons transrelativistic at $r_* \simeq 1{,}000$ would give $T_e \simeq 3 \times 10^{10}\ (r_*/5)^{-1/2}$ K

The γ-ray flux from the inner regions of the torus (which may include a redshifted positron annihilation line) would have only a small probability of being reabsorbed near the hole Nevertheless, the small number of interactions that will occur can produce sufficient electron–positron pairs within the funnel to complete the circuit and allow electric current to flow through the hole For example, to support an electromagnetic power of 10^{44} erg s^{-1} in the funnel, a current of 3×10^{17} A must flow, which requires a minimum pair creation rate of $\sim10^{36}$ s^{-1} This can be maintained by γ rays from the torus

If, as assumed above, the electrons and ions are indeed thermally decoupled when equation (5) is satisfied, then the inner part of the torus will radiate much less than $0\ 1\ Mc^2$, and this power is in the far IR or the γ-ray band But if, on the other hand, collective plasma effects couple the ions and electrons at all radii, then (see Fig 1) there will be a thin disk for $r \leqslant 50\ r_g$, radiating $\sim 0\ 1\ Mc^2$ with a spectrum peaking in the optical For $m_{-4} > 50\ \alpha_{-2}^2$, even Coulomb coupling of electrons and ions is efficient enough to cool the ions, and one would expect a thin disk radiating in the near UV When m is low, the predicted emission from galactic nuclei depends so drastically on whether or not the electrons and ions are coupled by plasma effects, that this issue can perhaps be settled observationally more readily than by the efforts of plasma theorists

The maximum power that can be self-consistently extracted from a black hole by a thick ion-supported torus, M being given, is achieved when α has the lowest value consistent with the electron–ion decoupling condition $m < 50\ \alpha^2$ Even if M is a free parameter, the maximum power than can be self-consistently extracted from a black hole by a thick torus supported by ion pressure is $\sim 10^{45}\ \alpha_{-2} M_8$ erg s^{-1} However, if strong magnetic fields are anchored in a dense radiation-pressure-supported torus[18–21], whose thermal luminosity is $\gtrsim L_{\rm Edd}$, there is no clearcut reason why the power extracted electromagnetically from the hole should not be orders of magnitude larger A model along these lines may be relevant to objects such as 3C273 where (in contrast to the radio galaxies) there is a nuclear thermal luminosity $\sim L_{\rm Edd}$, but where there is evidence also for a powerful relativistic jet

Astrophysical context

We have argued that, provided the viscosity parameter α is not too low and the electron–ion coupling is sufficiently weak, a two-temperature, ion-supported torus can be maintained around a massive black hole accreting gas at a very subcritical rate in a galactic nucleus The inner region of such a torus can collimate a pair of relativistic jets comprising electrons, positrons and electromagnetic fields If radio jets originate in the funnels of accretion tori, the latter are likely to be supported by ion pressure rather than radiation pressure in most observed cases The luminosity of the torus would then be far less than the kinetic energy flux in the jets (The scale of the observed jets is, of course, many orders of magnitude larger than the torus itself, so some further collimation process may also be operative)

If most of the power is extracted from a spinning black hole, a fuelling rate of $\sim10^{-3}\ M_\odot$ yr^{-1} suffices for most radio sources A 'baseline' value for M in galactic nuclei would be supplied by debris from stars which pass so close to the hole that they are tidally disrupted[4 32,33] This debris would have an angular momentum appropriate to an orbit at a few times r_g (for $M_8 \simeq 1$) but a specific binding energy of only $\sim10^{-5}\,c^2$ (ref 33) This debris would then form a torus extending out to $\sim10^5\ r_g$, a single disrupted star could then maintain $m \approx 10^{-4}$ for $\sim10^4$ yr

If the energy in radio source jets derives mainly from the spin of the central black hole, then the hole probably underwent a phase of rapid mass accretion at an earlier epoch One can speculate on a possible evolutionary sequence governed by accretion rate If $m > 10$, a radiation-supported torus can be formed. For $50\alpha^2 \leqslant m \leqslant 10$ the situation is less clear, but an ion-supported torus could possibly result, with most of the mass being contained within cool clouds or a thin disk

Disks with $m > 50\alpha^2$ will be strong sources of ionizing radiation, and should be associated with strong line emission from the nucleus Tori with $m < 50\alpha^2$ will be essentially invisible except as γ-ray sources Both may drive the strongest of extended radio sources Recent quasar observations have shown that the majority are radio-quiet, have small percentage polarization, and relatively low X-ray luminosity[50–52] Presumably these do not create large fluxes of relativistic particles, and are perhaps $\sim10^8\ M_\odot$ black holes surrounded by radiation-supported tori without dominant magnetic fields Seyfert galaxies may be similar, but with $\sim10^6\ M_\odot$ black holes The radio loud and (usually) X-ray luminous objects may then be associated with electromagnetically powered tori, the BL Lac and superluminal radio sources perhaps being viewed at small angles to the jet axis

Finally, the physics we have been discussing, with the exception of the detailed radiative properties of the torus, involves no intrinsic mass scale. Indeed, there may be an ion-supported torus around a $\leqslant10^6\ M_\odot$ hole in our galactic centre, and relativistic jets collimated by tori around stellar-mass black holes may exist within our Galaxy

Structural evolution of a crustal section in the western Himalaya

M. P. Coward*, M. Q. Jan†, D. Rex*, J. Tarney‡, M. Thirlwall* & B. F. Windley‡

Recent field work on the Kohistan complex in the Karakorum Range of North Pakistan has shown its stratigraphy to be repeated by several phases of tight to isoclinal folding. This reveals a close association between igneous activity and a late deformation and complicates the previously proposed island arc model.

AN exciting crustal section has recently been discovered in the Karakorum Range of North Pakistan[1,2] This was considered to be a complete section of an island arc (the Kohistan complex or sequence) thrust over rocks of the Indian plate and turned on end during Himalayan orogeny (for details of the regional setting, see ref 3) The arc was initially interpreted as a stratigraphic sequence from upper crustal sediments and volcanics in the north through tonalites and diorites to lower crustal granulites in the south. Our recent field work has shown a more complex structure, stratigraphy being repeated by several phases of tight to isoclinal folding. The Kohistan sequence forms a major tight syncline whose plunge varies over 90° and this folds a complete section through the crust, the lower crustal rocks having previously been isoclinally folded The Kohistan sequence was thrusted southwards over the gneisses of the Indian plate and the earlier arc structures were steepened to a near-vertical attitude Most of the tonalite–diorite suite was intruded during this deformation sequence, but some outlasted the deformation This close association between igneous activity and late deformation complicates a simple arc model

North–south traverse

Figures 1 and 2 show a simplified map and section of the Kohistan area adapted from refs 3, 4 and a new unpublished map by R A K Tahirkheli We consider here a north to south section from the Karakorum Ranges to the molasse deposits of the Indian plate In the Hunza valley in the north there is a chaotic arrangement of lithologies including limestones, sandstones, conglomerates, basic volcanics and ultrabasic rocks such as serpentinites, meta-harzburgites, talc-carbonate and talc-chlorite schists, all occurring as lenses several kilometres long separated by chloritoid slates These slates increase in grade rapidly northwards to garnet–staurolite mica schists intruded by the granodiorites of the Karakorum batholith The slates and schists contain a well developed schistosity folded around a large-scale, gently dipping synform (see Fig 2) This chaotic pile of lithologies resembles a large-scale tectonic mélange which is situated along the northern suture

To the south there are gabbros, basic volcanics, including spectacular sections of deformed pillow lavas, volcaniclastic sediments and greywackes folded into tight large-scale anticlines and synclines Further south these sediments and volcanics are invaded by tonalites, diorites and large pegmatite swarms, locally constituting 30% of the rock volume Between these intrusions there are screens of graded greywackes and pillow lavas from which younging directions can be obtained (see Fig 1) This sequence extends for ~70 km from the northern suture The dominant structures are large-scale, upright antiforms and synforms, whose hinges plunge steeply NNE parallel to mineral lineations down the dip direction of the cleavage The major structure shown on the map is a westward-facing, steeply plunging anticline at Gilgit and a complementary major syncline with a half wavelength of >50 km together with common smaller-scale parasitic folds These structures bring the major stratigraphy from north of Gilgit southwards to Jaglot, particularly repeating the spectacular pillow lavas seen in the north This same Jaglot syncline probably continues westwards to the central part of Kohistan where it contains the Eocene Kalam volcanics[5] and underlying sediments, in this region the syncline has a more horizontal plunge

On the south limb of the syncline one passes down into a vast stratiform cumulate complex containing chromite-layered dunites, troctolites, gabbros and predominant norites with spectacular phase graded units There are very spectacular and abundant graded units which have allowed numerous younging directions to be obtained In the Chilas area these layers are deformed into large-scale steeply plunging folds, parasitic on the Jaglot syncline However, there are changes in facing direction as shown by the cumulate grading indicating an earlier major isoclinal fold phase The central part of the Chilas complex is composed of a zone of ultramafic rock and this youngs to metanorite at the northern and southern margins The whole Chilas complex is interpreted as one isoclinal anticline refolded by Jaglot syncline age structures. The complex has suffered metamorphism of two pyroxene granulite facies, the minerals of which are aligned in the fabric of Jaglot syncline age

There are two important later stages of deformation which affect both the Chilas complex and the metasediments and igneous rocks to the north A phase of southward dipping, small-scale folds produces crenulation cleavage in the more schistose rocks, possibly related to the nearly recumbent fold in the Hunza valley Later deformation produced a major conjugate set of NW–SE dextral and NE–SW sinistral trending shear zones with dominantly strike-slip sense of displacement these vary from ductile to brittle, and from phyllonites of amphibolite–greenschist facies to pseudotachylites

To the south of the Chilas complex there is a complex sequence of metasediments, amphibolites, gabbros, deformed granites and pegmatites and post-tectonic granites Most rocks show two phases of deformation the dominant second phase deforms early fabrics and folds, and produces steeply-plunging folds parasitic on the Jaglot syncline as shown in Fig 2

At Patan there is the Jijal complex[6] of chromite-layered dunites and granulites, which we interpret as part of the Chilas complex metamorphosed to a high-pressure (garnet–clinopyroxene) granulite grade This interpretation requires a first-phase tight syncline between the Chilas and Jijal complexes The Jijal complex shows two phases of deformation similar to those described above, the first fabric of which is difficult to detect, being largely overgrown by granulite facies assemblages To the south the rocks become intensely sheared and metamorphosed to the amphibolite facies All these structures become more

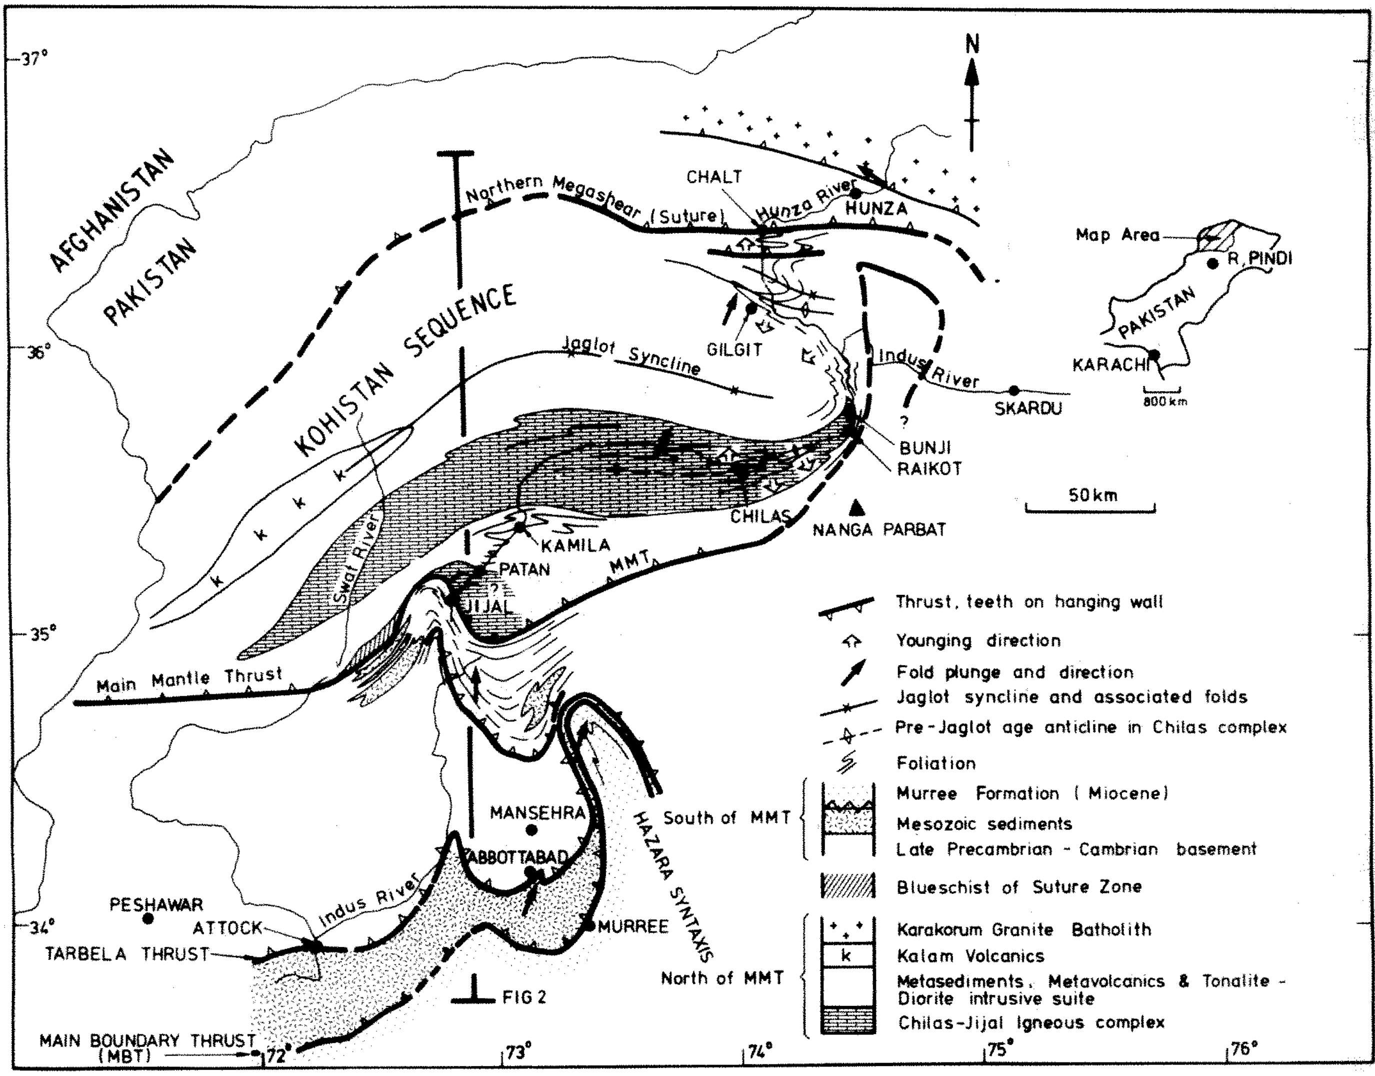

Fig. 1 Map of the Kohistan region showing the main structures (modified from refs 2 and 4).

gently dipping to the south, so that near Jijal the fabrics are flat-lying or dip only gently northwards. Along strike to the south-west there is a 10–15 km wide thrust wedge of blueschists[7] along the Main Mantle Thrust (MMT) (Fig. 1), though to the east, around the Nanga Parbat bulge (Fig. 1), no blueschists occur, the MMT is difficult to detect and the obvious faults and shears are late structures which post-date the folding.

At Jijal a major shear zone, the MMT[1,2], carries the Jijal complex and the Kohistan sequence southwards over quartzo-feldspathic gneisses of the Indian plate containing an intense fabric folded by recumbent, nearly isoclinal folds with hinges plunging to the NNE. Both sets of structures are folded around large-scale upright F_3 folds. The gneisses with intense deformation and isoclinal folds can be followed for 10–20 km south of the MMT and contain infolded synclines of Mesozoic cover rocks (marbles, graphite schists and conglomerate). Further south where deformation decreases, the unconformity can be seen between these sediments and the underlying basement gneiss. Where least deformed by Himalayan shearing, as at Mansehra, this basement appears as a homogeneous porphyritic

Fig. 2 Simplified tectonic cross-section of the region. For location and caption see Fig. 1. The dip and position of the major thrusts at depth is uncertain. Evidence for flat-lying thrusts beneath the Indian plate is given in ref. 13. Vertical scale = horizontal scale.

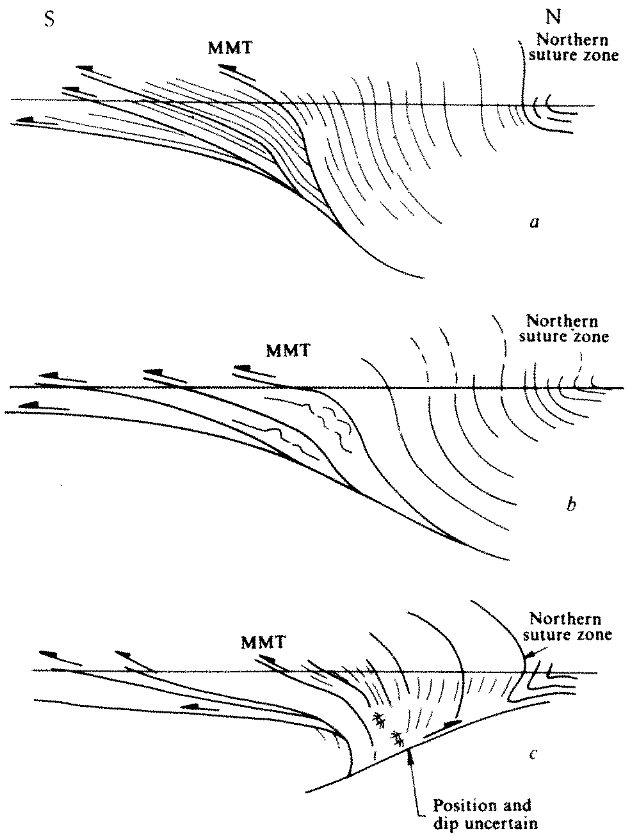

Fig. 3 Model section to show how Kohistan sequence achieved its steep dip: *a*, due to climb and fanning of thrusts to the south; *b*, due to folding above a decoupling horizon[9]; *c*, due to back thrusting. The structure of the Kohistan complex is simplified to show approximate dips of foliation and fold axial planes. Vertical scale = horizontal scale.

granite which has a Rb/Sr whole rock isochron age of 516± 16 Myr (ref. 8). This granite has a contact aureole against pelitic sediments of presumed late Precambrian age. These basement rocks are thrust southwards over Mesozoic sediments near Abbottabad and together with the Mesozoic sediments they are further thrust over mid-Oligocene to mid-Miocene red sandstones and shales (the Murree Formation). All these rocks are folded into a major steeply-plunging tight anticline (Fig. 1) which is a first phase structure in the Miocene and at least a third phase structure in the Mesozoic sediments and their gneissic basement. To the south there are even more thrusts in sediments ranging in age from Palaeocene to Cambrian, flooring in a blind thrust in the sediments above the basement.

Discussion

The MMT clearly separates crustal blocks of two different ages, origin and lithology[1,2]. The gneisses to the south form part of the late Precambrian–early Palaeozoic segment of the Indian plate, while to the north no old basement has been found, but rather deformed sediments and igneous rocks of Mesozoic–Cenozoic age. The Mesozoic–Cenozoic Kohistan sequence was considered to represent an island arc[1,2], but our studies show this to have a more complicated structural history and a compound origin.

The lower crust is made up of the basic–ultrabasic Chilas complex which is >300 km long and >8 km thick, and is thus one of the largest intrusions in the world. Above this there are mainly pillow lavas and greywackes intruded by gabbros, diorites and tonalites. The early isoclines are developed in the lower crustal rocks of the southern Kohistan sequence associated with granulite facies metamorphism. These structures are folded by one of the largest synclines known, which folds the whole upper crust of Kohistan. Its synclinal axis changes from near horizontal in the west to steeply NNE near the Indus River parallel to the Himalayan overthrust direction. This major syncline and related structures seem to be related to the MMT, though the eastern continuation of the MMT is difficult to trace around the Nanga Parbat syntaxis which has the form of a late fold with late faults along its western margin. In Kohistan the MMT marks a major suture bringing granulites against blueschists and amphibolites. The immediately underlying Indian plate contains a 10–20 km wide, gently dipping shear zone with Mesozoic cover tightly infolded into basement gneiss. To the south there are more discrete thrust planes, the floor thrust of which climbs southwards from basement to progressively higher levels of sediment. These structures propagated southwards: the earlier thrusts and folds in the north are refolded by structures developed in the south. The Kohistan sequence north of the MMT has been backfolded to become vertical to southerly dipping west of the Nanga Parbat syntaxis. The origin of this backfold is uncertain: one method of modelling would be to produce the above-described major thrusts in the form of an imbricate fan analogous to that in accretionary wedges[9] (see Fig. 3*a*). Alternatively, the more northern thrusts could be folded into a steep orientation above a low-level decoupling horizon analogous to that suggested for the Swiss Alps (Fig. 3*b*)[10]. In both these models the depth to the decoupling zone would be at least 100 km below the present erosion surface (Fig. 3*a*, *b*). In the Ladakh area, however, 200 km along the strike to the east of Kohistan, there are southward-dipping faults overthrusting to the north[11], and similar thrusts occur along the Indus suture in the central Himalaya[12]. Possibly the backfold is related to uplift on these faults (Fig. 3*c*).

Conclusion

One important conclusion from our study is that the predominant diorite–tonalite igneous activity in northern Kohistan is late to post-tectonic; some of it certainly postdates the Jaglot syncline and may postdate the backfolding. This conclusion is supported by a preliminary study of the Skardu area, east of the Nanga Parbat, where most granites, tonalites and gabbros postdate the intensely deformed metasediments and volcanics. This throws doubt on the contribution of this igneous activity to the development of the island arc. The problem of the origin of these diorites and tonalites may be solved by isotope and trace element geochemistry, at present underway at Cambridge, Leeds and Leicester.

The other exciting feature of the Kohistan area is the size of the structures involved. The Kohistan complex is now up to 150 km thick though this is largely the result of two phases of folding; little evidence has been found for thrust repetition as originally suggested by Bard *et al.*[2]. The Jaglot synform is one of the largest reported structures in the world and involves deformation of the whole crust with decoupling at considerable depth (>100 km) in the mantle. Similar decoupling depths are indicated by the different models to explain the backfolding (Fig. 3).

Cellular origin and role of mink cell focus-forming viruses in murine thymic lymphomas

Sisir K. Chattopadhyay[*†‖], **Miles W. Cloyd**[‡], **David L. Linemeyer**[§], **Marilyn R. Lander**[*†], **Elaine Rands**[*] & **Douglas R. Lowy**[*]

Embryo DNA of AKR mice contains several copies of intact mink cell focus-forming (MCF)-like env *gene sequences with a proviral structure. In spontaneous thymic tumours, these MCF-like* env *sequences have regularly recombined with a specific region of the 3′ end of ecotropic* env. *This specific recombination is probably a critical event in the pathogenesis of spontaneous AKR tumours.*

MURINE leukaemia viruses (MuLVs) are endogenous to laboratory mice[1-3]. The MuLVs of these mice have been divided into three related classes on the basis of their host range in tissue culture, which is determined by the viral envelope glycoprotein (gp70) encoded by the viral gene *env*[4]. These classes are: ecotropic, which infect only murine cells; xenotropic, which replicate primarily in heterologous cells; and mink cytopathic focus-forming (MCF) viruses, which grow in both murine and heterologous cells[5-8]. Biochemical studies of viral nucleic acids have suggested that MCF viruses are recombinants between ecotropic MuLV and endogenous *env* sequences related to xenotropic viruses[9,10].

Among laboratory mice, the AKR strain[11] has been intensively studied because of its high incidence of MuLV-associated spontaneous T-cell leukaemias, which originate in the thymus. Some steps leading to the development of this thymic disease have been determined, but many aspects of this complex process remain to be elucidated[12]. Each AKR mouse cell contains in its chromosomal DNA one or more complete copies of an ecotropic MuLV genome (proviral DNA)[13-16]. This viral genome is usually spontaneously activated shortly before birth, leading to high levels of circulating virus throughout the animal's life[17]. This ecotropic virus expression is apparently necessary but not sufficient for tumour development, which occurs only after the animal is at least 6 months old[18]. MCF viruses have been isolated primarily from preleukaemic thymuses and from tumour tissue[5,6], suggesting that MCF viruses may represent a more proximate cause of the tumour.

The origin and role of MCF viruses in tumorigenesis, which we have studied here, are still incompletely understood. The endogenous non-ecotropic viral sequences which presumably participate in the formation of MCF viruses have not been identified in normal cells, but it is known that AKR and other mice contain multiple copies[2,3] of sequences homologous to part of the complete AKR ecotropic viral genome. In addition, only certain MCF viruses are oncogenic[19]. It therefore appears that virological factors in addition to the expanded *in vitro* host range have a significant role in tumorigenesis.

In this study, we have used restriction endonucleases and a viral probe specific for MCF and xenotropic *env* sequences to map the viral sequences in high molecular weight DNA from AKR mouse embryos and from spontaneous and MCF virus-induced tumours. These maps have been compared with those recently developed for the DNAs of MCF viruses[20], where consistent differences were noted between DNAs of pathogenic and non-pathogenic MCF viruses. We have found: (1) AKR embryo DNA contains ~10 copies of apparently complete *env* sequences closely related to those found in MCF viral genomes; (2) these endogenous MCF-like *env* sequences resemble the *env* of the non-pathogenic MCF viruses more closely than they do those of pathogenic MCF viruses; (3) at least some copies of these *env* sequences have the structure of endogenous proviruses; (4) spontaneous AKR tumours are clonal in origin and contain recombinant viral DNA with the same structure as that found in pathogenic MCF viral DNAs. The results suggest that specific recombinational events between the endogenous MCF-like sequences and ecotropic viral sequences are a prerequisite for the establishment of AKR tumours.

Physical maps of ecotropic, xenotropic and MCF viral DNAs

Before analysing the AKR high molecular weight DNA, we will summarize the results of physical mapping studies of unintegrated DNAs of ecotropic, xenotropic and MCF viruses from AKR and other strains so that these maps can be compared with those generated here for endogenous non-ecotropic viral sequences in the high molecular weight DNA (Fig. 1)[20,21]. The viral DNAs, which are 8.8 kilobases (kb), contain three genes: *gag* (spanning 1.0–2.7 kb; map locations are given by their distance from the left (5′) end of the viral DNA), which specifies the virion core proteins, *pol* (2.7–5.8 kb), which encodes the reverse transcriptase, and *env* (5.8–8.2 kb), which codes for the virion envelope proteins gp70 and p15E (see Fig. 1) (refs 22–26 and C. Van Beveran and I. M. Verma, personal communication). The p15E sequences, which begin at ~7.5 kb, are located to the right of those which encode gp70 (refs 24–27 and C. Van Beveran and I. M. Verma, personal communication). The viral DNAs are flanked at each end by 0.6 kb of repeat sequences called the long terminal repeat (LTR).

As predicted from earlier studies of viral RNA oligonucleotides[28], each MCF viral DNA was unique, each was apparently composed of ecotropic and non-ecotropic sequences, and each contained non-ecotropic *env* sequences which shared restriction endonuclease sites with xenotropic *env* sequences (such as *Eco*RI at 6.9 and *Bcl*I at 7.0 kb, Fig. 1). However, some sites (such as *Bam*HI at 6.2 kb) were unique to MCF viruses, suggesting that the non-ecotropic sequences of MCF viruses might not be derived from proviruses of known xenotropic viruses. In addition, a consistent difference between the viral DNAs of non-pathogenic and pathogenic MCF viruses was that pathogenic MCF viral DNAs contained an *Xba*I site in p15E at 7.7 kb which was apparently derived from the ecotropic viral parent, while non-pathogenic MCF viruses did not have this site. Finally, in certain MCF viral DNAs, the span of the inferred segment of non-ecotropic sequences was much greater than only part of the gp70 coding region (Fig. 1). These results suggested

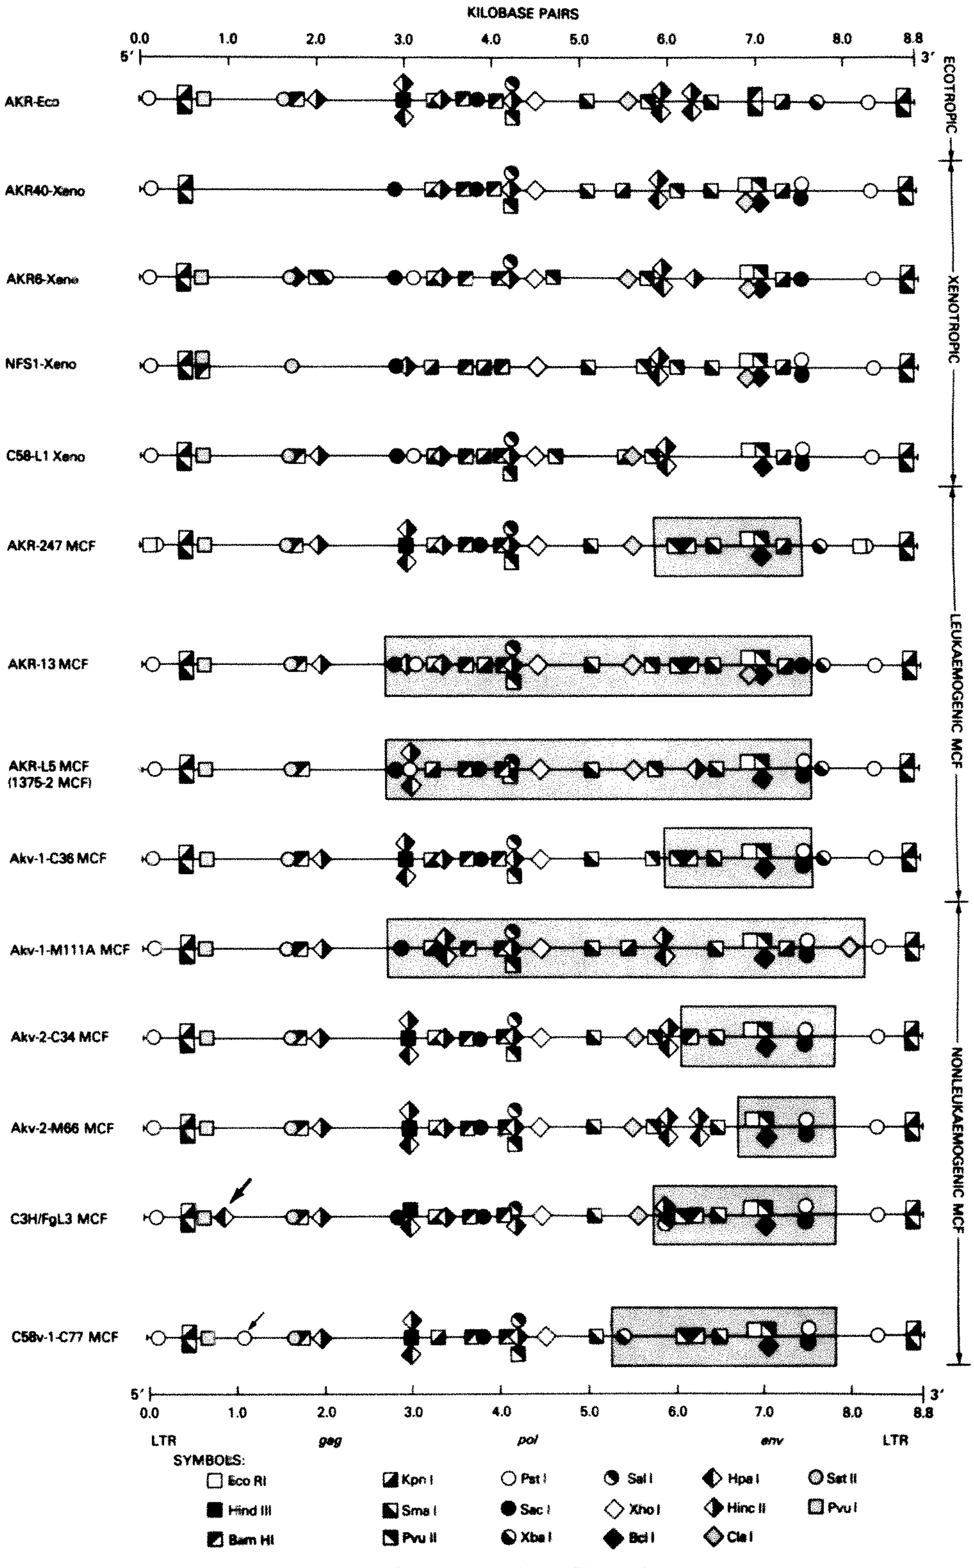

Fig. 1 Comparison of linear restriction endonuclease maps of representative ecotropic, xenotropic and MCF murine leukaemia viral DNAs. The viral DNAs are grouped according to the viral host range and within MCF viruses according to their disease-inducing capability. Each symbol corresponds to an enzyme as indicated in the figure. AKR-eco (ecotropic virus isolated from an AKR mouse) is virtually identical to ecotropic viruses of many inbred strains of mice (the strains and isolates analysed are: *Akv-1*, two isolates; *Akv-2*, two isolates; C58, three isolates; C3H/Fg, three isolates; PL, three isolates; F, one isolate; BALB/c, one isolate) and of *Mus musculus molossinus*[20,21]. Nomenclature and origin of various viruses have been described previously[20,21]. Each MCF DNA has been assumed to contain a continuous insert of non-ecotropic sequences, which may represent oversimplification in some instances. In general, the length of this insert (depicted by the wide bar) represents a minimum estimate, based on the presence of xenotropic or MCF-specific sites and/or the loss of sites common to ecotropic and xenotropic DNAs. The *Hpa*I site at 0.8 kb in C3H/FgL3 MCF and the *Pst*I site at 1.0 kb in C58v-1-C77 MCF (shown by arrows) are not found in ecotropic MuLVs, but have not been considered in the estimated segment of non-ecotropic sequences. These maps were derived from the unintegrated proviral DNAs as described in detail elsewhere[20,21,50]. Briefly, cells were infected with MuLV from chronically infected cells and DNA was extracted from them by the Hirt[51] procedure 18 h after infection. DNA from the Hirt supernatant was used as the starting material for restriction endonuclease digestion. Unintegrated proviral DNAs were digested with various enzymes, electrophoresed, transferred to nitrocellulose filters[52] and hybridized with ^{32}P-cDNA synthesized either from 70S viral RNA or by nick-translation of molecularly cloned viral DNAs. The cleavage products of each enzyme were ordered and oriented for each viral DNA by hybridization of digested DNAs with a 5' probe (the 4.6-kb *Sma*I fragment spanning 0.5–5.1 kb of AKR ecotropic MuLV DNA), a 3' probe (the 1.7-kb *Sma*I fragment spanning 7.0–8.7 kb of the ecotropic DNA) derived from molecular clone AKR MuLV 623 DNA[50] or a full xenotropic or MCF probe after single and/or double digestion of various Hirt DNAs with restriction endonucleases.

that the gp70 (and p15E) of at least some MCF viruses might be derived entirely from non-ecotropic sequences and that the *env* sequences which encode the expanded *in vitro* host range of MCF viruses might be found in high molecular weight DNA of normal cells.

Isolation of a DNA fragment specific for MCF and xenotropic *env*

To probe the high molecular weight DNA for the endogenous sequences which might give rise to the non-ecotropic portion of MCF viruses, we cloned in pBR322 a viral DNA *env* fragment which hybridized to MCF and xenotropic viral DNAs but not to ecotropic viral DNAs. This viral probe, designated BE, is composed of the 0.7 kb between a *Bam*HI and *Eco*RI site in *env* of the Friend spleen focus-forming virus (SFFV) DNA[29], a helper-dependent MuLV whose *env* is closely related to those of MCF viruses[30]. This region in SFFV corresponds exactly to the segment in some MCF viral DNAs between the *Bam*HI site at 6.2 kb and the *Eco*RI site at 6.9 kb (see diagram in Fig. 2). The BE fragment was characterized by radioactively labelling it and incubating it with Hirt supernatants containing ecotropic, xenotropic or MCF viral DNAs: the probe hybridized strongly to MCF DNAs and moderately to xenotropic DNAs, but not to ecotropic DNAs (Fig. 2). Similar results were obtained with the analogous *Bam*HI–*Eco*RI fragment derived from cloned MCF 247 DNA (data not shown).

Embryo DNA contains MCF-like *env* sequences

We then used the BE fragment to probe AKR embryo DNA for the presence of endogenous sequences from which the non-ecotropic *env* sequences of MCF viruses should have been derived (Fig. 3*b*, *c*). Hybridization of the BE probe to *Bam*HI-digested embryo DNA was used to estimate the number of copies of cross-reacting sequences in this DNA, as the BE probe should hybridize to cell–virus DNA junction fragments in high molecular weight DNA digested with this enzyme. *Bam*HI digestion (Fig. 3*b*) yielded $\sim$12–15 fragments, indicating that there are multiple copies in embryo DNA of sequences which cross-hybridize with the BE probe.

We had previously found that *env* of many non-pathogenic MCF viral DNAs had a *Bam*HI site at 6.2 kb, all had an *Eco*RI site at 6.9 kb and a *Bcl*I site at 7.0 kb, some had a *Kpn*I site at 7.3 kb and all had a *Pst*I site at 7.5 kb, a *Kpn*I site at 7.3 kb, a *Pst*I site at 7.5 kb and a *Kpn*I site at 8.7 kb (in the LTR) (see Figs 1, 3). Several copies having these sites were also present in the embryo DNA.

For example, *Eco*RI–*Bcl*I digestion (Fig. 3*b*) shortened each *Bcl*I fragment by 0.1 kb, which indicated that each fragment contained an *Eco*RI site 0.1 kb away from a *Bcl*I site, as was also the case in *env* of every xenotropic and MCF viral DNA. *Bam*HI–*Eco*RI digestion (Fig. 3*c*) gave a more simplified pattern than did *Bam*HI digestion; the intense 0.7-kb fragment corresponded to the *Bam*HI–*Eco*RI fragment spanning 6.2–6.9 kb in many MCF viral DNAs, suggesting the presence of several copies of this fragment in embryo DNA. Endogenous fragments which contained the *Kpn*I site at 7.3 kb should yield a 1.1-kb *Bam*HI–*Kpn*I fragment (6.2–7.3 kb), while those lacking this *Kpn*I site should yield a 2.5-kb *Bam*HI–*Kpn*I fragment (6.2–8.7 kb); these are the two prominent fragments of this double digestion (Fig. 3*c*). The 7.5-, 2.9- and 2.4-kb *Pst*I fragments were apparently all shortened by 0.6 kb when cleaved with *Eco*RI (Fig. 3*b*), which suggests that the right end of these *Pst*I fragments all terminate at 7.5 kb.

It was also important to determine if the *Bam*HI fragments contained an *Xba*I site corresponding to that found in p15E at 7.7 kb in pathogenic MCF viruses. Hybridization of the BE probe to *Bam*HI–*Xba*I-digested AKR embryo DNA (Fig. 3*c*) did not yield a 1.5-kb fragment which would correspond to the *Bam*HI–*Xba*I fragment found in pathogenic MCF viruses such as MCF247. The *Xba*I site at 7.7 kb noted in ecotropic viruses and in pathogenic MCF viruses was therefore not covalently linked to the 6.2-kb *Bam*HI site in the embryo DNA. Taken together, the results described above demonstrated that AKR embryo DNA contained multiple (we estimate $\sim$10) copies of apparently complete *env* sequences with the same restriction sites mapped in non-pathogenic MCF viral DNAs, and at least some of these *env* sequences were linked on their right to an LTR. It is probable that several of these copies can participate in the formation of MCF viruses, as their heterogeneity with respect to the *Bam*HI site at 6.2 kb is correlated with heterogeneity at this site in MCF viruses (Fig. 1).

Endogenous MCF-like *env* sequences are part of proviral DNAs

We have also found evidence that at least some of these MCF-related *env* sequences are part of proviral DNAs, as they are also linked on the left to LTR, *gag* and *pol* sequences. As seen in Fig. 2 and Fig. 3*b*, the BE probe hybridized to a prominent 7.5-kb *Pst*I fragment, which is the expected length of a proviral fragment spanning sequences from a *Pst*I site near the left end of the LTR to a *Pst*I site at 7.5 kb (both of these *Pst*I sites have been found in xenotropic and MCF viral DNAs, see Figs 1, 3). Most of the copies that make up this *Pst*I fragment do extend to 7.5 kb, because, as noted previously, *Eco*RI digestion apparently shortens this fragment by 0.6 kb. In addition, this 7.5-kb *Pst*I fragment hybridizes to probes specific for the 5′ end (5′ probe), middle portion (M probe) and LTR (L probe) of viral DNAs (Fig. 3*a*). (The 8.2-kb *Pst*I fragment which hybridized to each probe except the BE probe represents the endogenous ecotropic proviral DNA cleaved at the *Pst*I site in each LTR[15].) Several *pol*–*env* fragments which corresponded to fragments in MCF viral DNAs in Fig. 1 whose non-ecotropic sequences were inferred to include the *pol* region were also noted in embryo DNA. For example (Fig. 3*b*), the 5.3-kb *Kpn*I fragment corresponded to a fragment in L5 MCF (3.4–8.7 kb) and the 1.8-kb *Kpn*I fragment to a fragment in M111A MCF (5.5–7.3 kb).

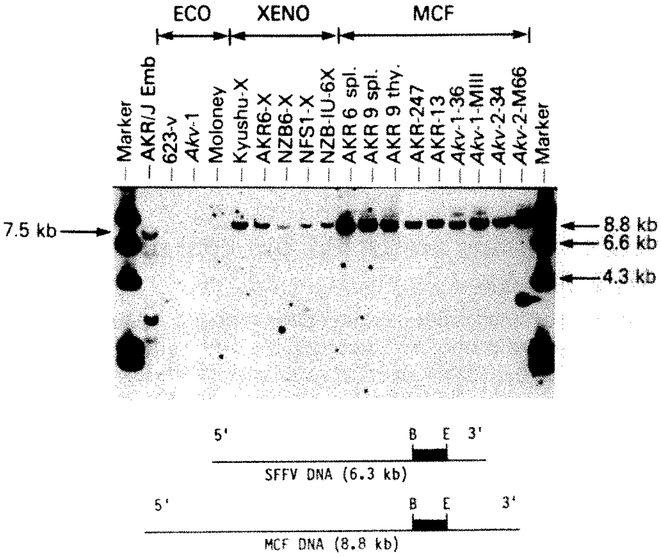

Fig. 2 Southern blot showing selective hybridization of the BE probe to MCF and xenotropic viral DNAs, but not to ecotropic viral DNAs. The BE probe, derived from a 0.7-kb *Bam*HI–*Eco*RI fragment of Friend SFFV DNA[29], was molecularly cloned (by D.L.L.) in pBR322 via the *Bam*HI and *Eco*RI sites. In the upper diagram, the location of the BE probe sequences in SFFV DNA is represented by the heavy line between B (= *Bam*HI) and E (= *Eco*RI). Also shown are the sequences in the BE probe which correspond to the 6.2–6.9-kb region in MCF viruses in *env*, as described in the text. Unintegrated ecotropic (eco), xenotropic (xeno) and MCF viral DNAs were isolated by the Hirt procedure 16–18 h after infection of permissive cells as described in Fig. 1 legend. Hirt supernatant DNAs (5–7 μg each for ecotropic viruses, 15–20 μg of each for xenotropic and MCF viruses) were electrophoresed in horizontal 0.7% agarose gels (35 V, 16 h), transferred to nitrocellulose filters and hybridized with ^{32}P nick-translated 0.7-kb BE probe. The amount of Hirt DNA added for each virus gave an 8.8-kb band of similar intensity when hybridized to its homologous probe (data not shown). *Pst*I-digested high molecular weight AKR/J embryo DNA was electrophoresed in the lane marked AKR/J Emb. 623-v indicates the 623 ecotropic MuLV isolated from NIH3T3 cells transfected with AKR MuLV 623 DNA. The origin of the other viruses has been described previously. Marker was *Hin*dIII-digested ^{32}P-labelled λ DNA. The numbers beside the panels indicate the length of fragments in kb.

The above results therefore indicate that at least some of the endogenous sequences which hybridize to the BE probe are organized as proviral DNAs, as already shown for mouse ecotropic[15,16] and avian leukosis[31] viral genomes in embryo DNA. We have also found multiple copies of similar MCF-like sequences in other mouse strains, including BALB/c and NIH Swiss, and have molecularly cloned from high molecular weight DNA of BALB/c and NIH cells *Eco*RI fragments which hybridize strongly to the BE probe: each clone contains cell sequences linked to 6.9 kb of proviral DNA truncated at the (6.9 kb) *Eco*RI site (unpublished data).

Tryptic analysis of viral gp70s has suggested that this protein in MCF viruses is part ecotropic and part xenotropic, which has led to the hypothesis that the MCF gp70 is invariably a hybrid gene product[32]. However, the finding that the endogenous MCF-like *env* sequences closely resemble those in MCF viruses supports the alternative hypothesis[20,33] that the MCF phenotype assayed in culture may be encoded completely by the endogenous non-ecotropic *env* sequences. The development of MCF-specific gp70 assays[30,34–36] is also consistent with this hypothesis. Further, the MCF gp70 tryptic peptides which resemble ecotropic peptides, which have been localized to the amino terminus of this protein[37], are encoded in the BE probe, and the *env* sequences in the truncated BALB/c and NIH Swiss clones mentioned above resemble the *env* of MCF247 in that they contain the same *Pvu*II, *Bam*HI, *Sma*I and *Eco*RI sites between 6.1 and 6.9 kb (unpublished data). These data suggest that ecotropic-like gp70 peptides of the MCF viruses may be derived from the endogenous MCF-like *env* sequences. However, a direct answer must await biological studies of these endogenous sequences after they have been molecularly cloned intact.

AKR tumours are clonal and contain new MCF DNAs

Having characterized the endogenous sequences which hybridized to the BE probe, we examined the viral sequences in high molecular weight DNA from 19 spontaneous AKR tumours and from 11 tumours induced (accelerated) in AKR mice with MCF247 virus. Other studies with unfractionated probes have found new viral DNA fragments in tumour DNA[38-40]. The DNAs from MCF virus-induced tumours were used principally as controls for the spontaneous tumours, as it is known that the inoculated MCF virus can be recovered intact from these tumours[38].

The tumour DNAs were digested with *Bcl*I-*Xba*I and hybridized to three viral probes: the 5′ probe, to detect new MuLV sequences of any tropism; an ecotropic specific probe (the E probe shown below Fig. 3*a*) to detect viral DNAs with ecotropic gp70 sequences; and the BE probe, to detect viral DNAs with MCF gp70 sequences. As all three probes are composed of sequences located to the left of 7.0 kb, while the only *Bcl*I and *Xba*I sites in AKR MCF or ecotropic viral DNAs were located to the right of 7.0 kb, this digestion should reveal new left-hand cell–virus junction fragments with each probe.

Representative results are presented in Fig. 4. When thymic tumour DNA digested with *Xba*I/*Bcl*I was hybridized with the 5′ probe, novel fragments were detected in all MCF virus-induced tumours (Fig. 4*a*, tumours I 01 and I 02) and in eight of the spontaneous tumours. In Fig. 4*a*, one spontaneous tumour contained a novel fragment (S 02, arrow), while the other spontaneous tumour did not (S 01). Others[39,40] have also found new viral fragments in only some spontaneous AKR tumours, probably because of the high background of multiple endogenous fragments. The tumours induced with MCF247 virus contained several new copies of viral DNA, as denoted by haziness and new distinct bands of 7–9 kb. By contrast, the spontaneous tumours usually contained only a single novel fragment. For each MCF-induced tumour DNA, most of the new viral fragments hybridized to the BE probe (Fig. 4*b*), but other fragments hybridized to the ecotropic probe (Fig. 4*d*), indicating that the tumours were infected with both MCF and ecotropic viruses. By contrast, the new fragment detected with the 5′ probe in spontaneous tumours also hybridized with the BE probe (Fig. 4*b*, tumour S 02, arrow), but no new ecotropic fragments were detected in spontaneous tumours (Fig. 4*d*), despite the small numbers of endogenous ecotropic fragments. These results suggest that ecotropic viruses as such do not usually infect the cells before they become a tumour. (Since submission of this article, Yoshimura and Breda[41] have reported similar observations.) Thymic lymphocytes have been reported to be resistant to infection by ecotropic virus, and our failure to find additional ecotropic viral genomes in the spontaneous tumours is consistent with this observation[42,43].

We also determined that the AKR tumours were, as previously suggested[38,39], probably of clonal origin, as has already been demonstrated for avian leukosis virus-induced bursal tumours in chickens[44,45]. Each new fragment in the DNA of a given thymoma was found to be characteristic of all tumour tissue from a given animal, whether the tumour arose spontaneously or was induced by MCF247 (Fig. 4*c*, arrow). Note also that uninvolved intestinal tissue from leukaemic animals did not contain these new fragments. As the metastatic tumours contained the same new viral fragments as the primary

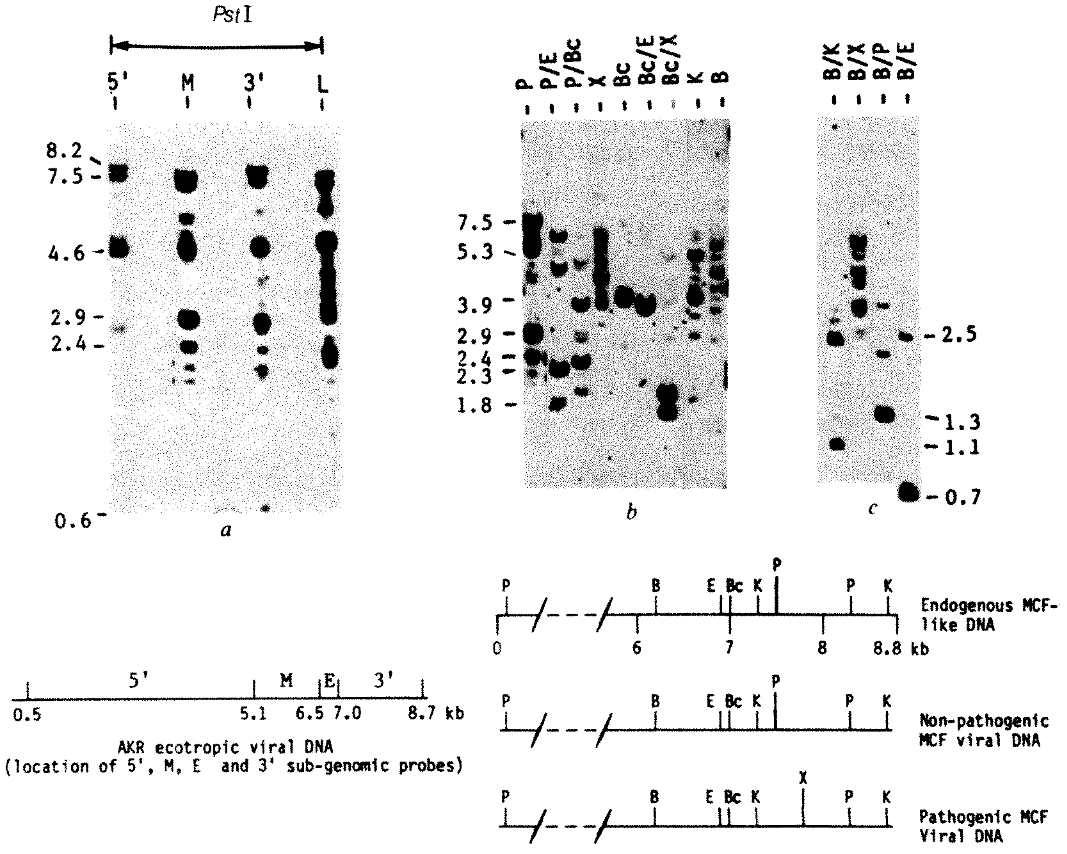

Fig. 3 Blot analysis of nonecotropic sequences of AKR/J embryo DNA. AKR/J embryo DNA was digested with various enzymes as indicated, electrophoresed in 0.5% agarose gels (35 V, 24 h), UV irradiated for 10 min, transferred to nitrocellulose filters and hybridized with various viral probes as described below. Fragment lengths are given in kb. In *a*, each lane contained *Pst*I-digested embryo DNA. The lanes labelled 5′, M and 3′ were hybridized to probes derived from cloned *Sma*I fragments of AKR ecotropic viral DNA as shown in the diagram below *a*. The 5′ probe spans 0.5–5.1 kb, the M probe spans 5.1–6.5 kb and the 3′ probe spans 7.0–8.7 kb. The 3′ includes 0.5 kb of LTR and will therefore hybridize to LTR sequences at the 5′ end of the viral DNAs in addition to hybridizing to sequences at the 3′ end of viral DNAs. The lane in *a* labelled L was hybridized to a probe composed of the LTR sequences of Harvey murine sarcoma viral DNA (provided by E. H. Chang, NCI); this probe also hybridizes to the LTRs of the viruses isolated from AKR mice. In *b* and *c*, the embryo DNA was hybridized to the BE probe, described in Fig. 2 legend. In these two panels and in the diagram below them, K = *Kpn*I, P = *Pst*I, B = *Bam*HI, X = *Xba*I, E = *Eco*RI, Bc = *Bcl*I. The deduced restriction endonuclease map of the non-ecotropic viral sequences in the embryo DNA has been shown in the map labelled 'endogenous MCF-like viral DNA'. These sequences have been compared with those found in non-pathogenic and pathogenic MCF viral DNAs. Viral sequences located rightward from the *Bam*HI site at 6.2 kb have been emphasized here. However, at least some of these endogenous MCF-like DNAs are organized as proviral DNAs (LTR, *gag*, *pol*, *env*, LTR), as noted in the text.

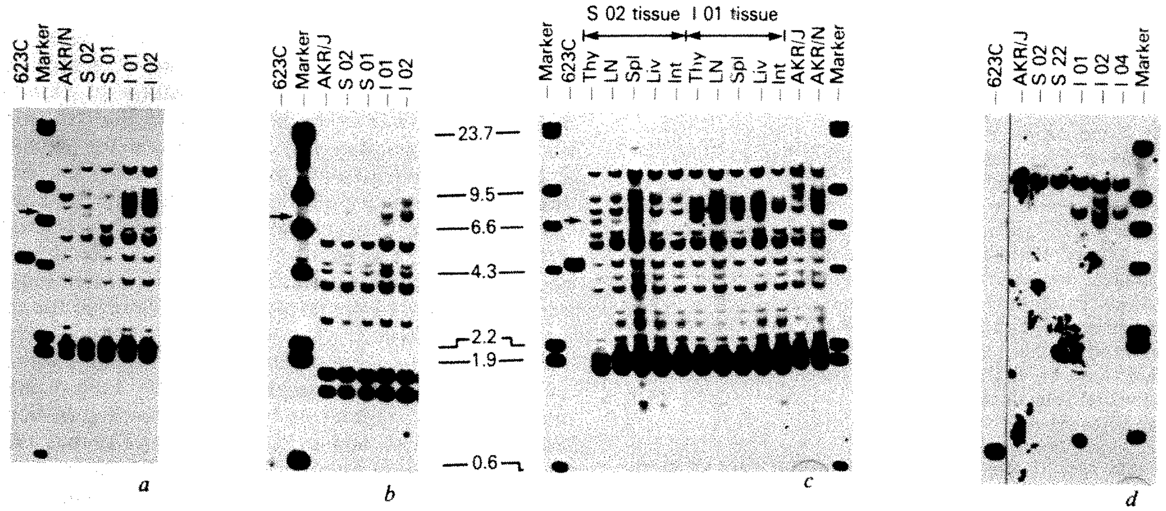

Fig. 4 AKR tumours are clonal in origin, contain new MCF viral DNA, but not new ecotropic viral DNA. *a* Shows that new viral DNA fragments are detected in some spontaneous tumours and all MCF virus-induced tumours; *b* shows that in spontaneous tumours the new fragments hybridize with the BE probe; *c* shows the clonal nature of the tumours; *d* shows that spontaneous tumours do not contain new ecotropic viral DNAs, but that MCF virus-induced tumours do. High molecular weight DNAs isolated from various spontaneous tumours (S) or MCF-induced tumours (I) were digested with *Bcl*I–*Xba*I, electrophoresed in 0.5% agarose gel (35 V, 24 h), UV irradiated for 10 min, transferred to nitrocellulose filters and hybridized with ^{32}P nick-translated viral probes: the 5′ probe (described in Fig. 3 legend) in *a* and *c*, the BE probe (described in Fig. 2 legend) in *b*, or an ecotropic-specific probe spanning 6.6–7.0 kb in AKR ecotropic viral DNA (labelled E in the diagram below Fig. 3*a*) in *d*. *Hin*dIII-digested ^{32}P-labelled λ DNA was used as marker and the number indicates length of the DNA in kb. In *a*, *b* and *d*, DNAs from thymic tumours were used. AKR/J and AKR/N indicates DNAs from embryos of these strains respectively. In *c*, Thy = thymus, LN = lymph nodes, Spl = spleen, Liv = liver, Int = intestine. Thymus, lymph nodes, spleen and liver contained tumours, while intestine did not. In each panel, the lane marked 623C represents *Sma*I-digested clone 623 AKR ecotropic viral DNA as a specificity control. In *d*, the AKR/J embryo DNA contains one more ecotropic fragment than does the DNA from the spontaneous tumours. This additional copy is present only in some AKR/J embryos (M. Martin, personal communication).

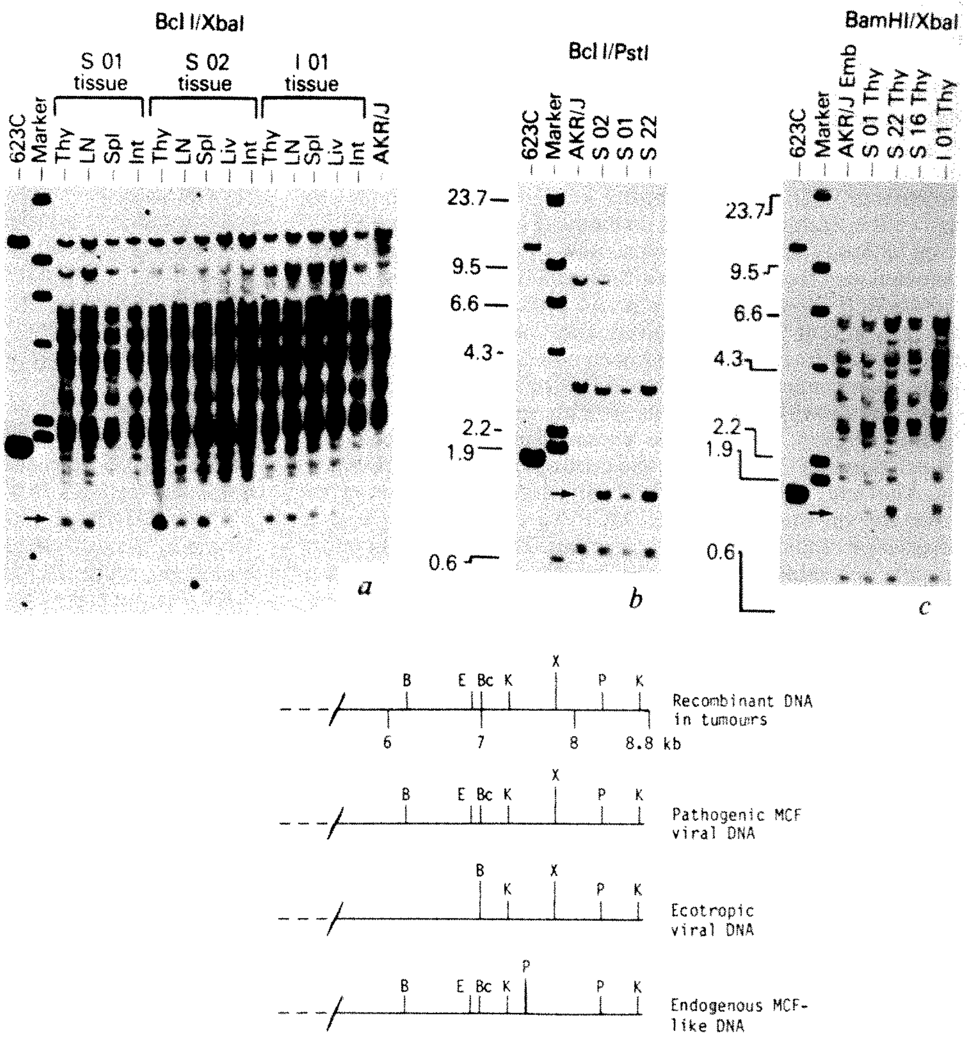

Fig. 5 Blot analysis of tumour DNAs showing that they contain recombinant viral sequences. S = spontaneous; I = induced; Thy = thymus; Spl = spleen; LN = lymph node; Liv = liver; Int = intestine. Thymic tissue was used for tumours in *b*. In each panel, the lane marked 623C contains *Sma*I-digested clone 623 viral DNA as a specificity control. High molecular weight DNAs were digested with various combinations of restriction endonucleases as indicated at the top of each panel, electrophoresed in 0.5% agarose gel (35 V, 24 h), UV irradiated, transferred to nitrocellulose filters and hybridized with a ^{32}P-labelled nick-translated 3′ probe (described in Fig. 3). In the diagram, the restriction enzyme sites of the recombinant viral *env*–LTR are shown on the map labelled 'recombinant DNA in tumours' (the presence of the *Kpn*I sites has not been determined experimentally).

Table 1 MCF virus in AKR thymus

	Infectious centres per 10^7 cells
AKR247 MCF-induced thymomas (19)	10,000–85,000
AKR spontaneous thymomas (7)	Trace, 1,000
Pre-leukaemic AKR (<6 months old) (9)	0*

Mink lung cells (CCL64) were plated at 2×10^5 cells per 60-mm dish in Dulbecco's modified minimal essential medium with 10% fetal calf serum. The following day, serial dilutions of thymus or spleen cells were plated as infectious centres onto the mink cultures in medium containing 16 μg ml^{-1} polybrene. The medium was changed 24 h later and the cultures were scored for characteristic MCF cytopathic foci (mink CPE) after confluence (days 5–7). The numbers in parentheses indicate the number of individual animals tested.

* Thymus and spleen.

thymoma, these results suggest that the tumours are of clonal origin.

Recombinant nature of new MCF DNA in AKR tumours

We also analysed the DNA of spontaneous tumours for recombinant viral DNA sequences, again using the cell DNA of MCF virus-induced tumours as positive controls for specific DNA fragments. In these studies, we hybridized the restriction endonuclease-digested tumour DNAs to the 3′-viral probe shown below Fig. 3*a*; this probe recognizes viral sequences to the right of 7.0 kb and includes the *Xba*I site at 7.7 kb which had been found in the DNA of pathogenic MCF viruses but had not been detected in the non-ecotropic sequences of AKR embryo DNA mapped with the BE probe in Fig. 3.

As noted earlier, all MCF viruses contained a *Bcl*I site at 7.0 kb, as did the endogenous non-ecotropic sequences in embryo DNA. Using the 3′ probe, the lack of linkage in AKR embryo DNA of the *Bcl*I site to an *Xba*I site corresponding to 7.7 kb was confirmed, as embryo DNA digested with *Bcl*I–*Xba*I did not contain the 0.7-kb *Bcl*I–*Xba*I internal viral fragment (Fig. 5*a*, arrow) found in the pathogenic MCF viruses and easily detected in the cell DNA of MCF virus-induced tumours (Fig. 5*a*, tumour I 01). However, the 0.7-kb *Bcl*I–*Xba*I fragment was detected in each spontaneous thymoma (Fig. 5*a*, S 01 and S 02), even in those tumours in which no new viral fragment had been detected with the other probes (tumour S 01). The recombinant 0.7-kb *Bcl*I–*Xba*I fragment was also present in all metastases, but was absent from uninvolved intestinal tissue. This same recombinant fragment has also been noted in thymomas arising in mice congeneic for *Akv-1* or *Akv-2* (ref. 40) and in C58 mice (data not shown). Such results strongly suggest that a recombinational event between the endogenous non-ecotropic *env* (which donated the *Bcl*I site) and ecotropic *env* (which donated the *Xba*I site) generated a hybrid *env* which corresponds to the structure of the pathogenic MCF viruses. The invariable association of this fragment with tumour DNA suggests that this specific recombination may be an important aspect of the oncological process in AKR tumours. (After this article was submitted, we learned that Quint *et al.*[46] and W. Herr and W. Gilbert (personal communication) had independently made similar observations in AKR tumours.)

In attempts to define further the region of recombination, we took advantage of the previously noted finding that many of the endogenous sequences which hybridized with the BE probe contained a *Pst*I site at 7.5 kb, while this site was not present in AKR ecotropic MuLV. If the recombination took place to the left of this *Pst*I site, then *Bcl*I (at 7.0 kb)–*Pst*I (at 8.2 kb), digestion should yield a 1.2-kb fragment; this was the case for all five spontaneous tumours studied (Fig. 5*b*, arrow). This result indicates either that recombination occurred between MCF sequences located to the right of 7.0 kb and ecotropic sequences located to the left of 7.5 kb, or that the recombination involved an unusual non-ecotropic *env* which lacked the *Pst*I site at 7.5 kb.

We also determined that the non-ecotropic sequences extended leftward at least to the *Bam*HI site at 6.2 kb, which had been noted in many endogenous non-ecotropic fragments mapped in embryo DNA. Hybridization of *Bam*HI–*Xba*I-digested tumour DNA to the 3′ probe or the BE probe, which should reveal a novel 1.5-kb fragment if the *Bam*HI site at 6.2 kb were now linked to the *Xba*I site at 7.7 kb, showed that this fragment was present in most (S 01 and S 22) but not all (S 16) spontaneous tumours (Fig. 5*c*, arrow; only 3′ probe results are shown). These results suggested that the non-ecotropic sequences extended leftward at least to 6.2 kb in most of these recombinant DNA fragments, as was also true for the pathogenic MCF viruses.

The mechanism by which the viral recombination has occurred is unknown although it probably follows infection of non-target cells by ecotropic virus. Relatively good homology to the left of 6.2 kb and to the right of 7.3 kb has been noted between ecotropic, xenotropic and MCF viruses, and the non-ecotropic sequences of MCF viruses usually include at least this 1-kb DNA segment[20,47]. It therefore seems reasonable to speculate that the non-ecotropic *env* of MCF virus genomes has been generated by homologous recombination through a double-crossover mechanism.

MCF virus production in tumours

As noted above, tumours induced experimentally by inoculation with MCF virus contained several new MCF viral DNA fragments, whereas the DNA of spontaneous tumours contained few new viral DNA fragments. We therefore sought to determine whether these biochemical differences would be reflected biologically in the frequency of virus-positive cells in MCF virus-induced tumours versus spontaneous tumours. By infectious centre assay (Table 1), no more than 0.01% of the thymoma cells from spontaneous tumours were releasing infectious virus whereas a much higher proportion of the cells from tumours induced by experimental inoculation with an MCF virus released MCF virus. These results therefore correlate with the biochemical data.

The mechanism underlying the low MCF virus production in spontaneous tumours remains to be elucidated. One attractive hypothesis is that the MCF viral sequences in the spontaneous AKR tumour cells is defective for replication. This mechanism has recently been noted in avian leukosis virus-induced bursal tumours[44,45]. Alternatively, the virus may be unable to be expressed efficiently in tumour cells. However, the release of MCF virus from a significant proportion of the cells in tumours induced experimentally by MCF247 does not support this conjecture.

Significance of recombinant viral sequences

The presence in spontaneous tumours of recombinant *env* sequences with a structure similar to that found in pathogenic MCF viral DNAs, combined with the lack of new ecotropic viral DNAs in the tumours, suggests that MCF viruses with recombinant *env* represent a more immediate inducer of spontaneous AKR lymphomas. The consistent association of the tumours with sequences present in pathogenic MCF viruses (and their absence from non-tumour tissue) suggests that this specific rearrangement of endogenous sequences is an important step in the development of the spontaneous tumours, perhaps by altering the differentiation state or the proliferative capacity of the target cell directly[48] or by promoter insertion[49]. The non-pathogenic nature of MCF viruses that have apparently acquired the endogenous MCF-like *env* without also retaining the ecotropic virus-derived sequences around the *Xba*I site at 7.7 kb suggests that activation of those endogenous non-ecotropic sequences is not by itself sufficient for tumour induction. Rather, pathogenicity occurs only after certain specific recombinational events between ecotropic virus and the endogenous MCF-like viral sequences. We presume that the non-ecotropic sequences facilitate adsorption and penetration of the virus into the target tissue. The function of the ecotropic sequences around the *Xba*I site is not known. However, they may also be important for infection of the target tissue, as pathogenic MCF viruses replicate better in the thymus than do the non-pathogenic viruses we have studied[19].

We thank Drs Alan Rein and Michael Potter for a critical reading of the manuscript, Dr Wallace Rowe for tumour tissues from *Akv* congeneic mice, and Mrs Lorraine Shaughnessy and Mr Harry Schaefer for preparation of the manuscript. This research was supported in part by a contract from the National Cancer Institute to Meloy Laboratories.

The highly polymorphic region near the human insulin gene is composed of simple tandemly repeating sequences

Graeme I. Bell, Mark J. Selby & William J. Rutter

Department of Biochemistry and Biophysics, University of California, San Francisco, California 94143, USA

The sequence of the highly polymorphic region near the human insulin gene, which begins 363 base pairs before the start of transcription and extends upstream, indicated that it is generated by variation in the number and arrangement of members of a family of tandemly repeating nucleotides whose structure is related to ACAGGGGTGTGGGG. Another 15-base pair sequence, repeated twice near the human gene, is located ~325 base pairs on either side of the polymorphic region. One member is in the transcriptional control region.

THE human insulin gene region of two human chromosome 11 homologues has been isolated and characterized[1–5]. The organization and structure of the 1,430-base pair (bp) segment encoding the insulin mRNA precursor and ~40 kilobases (kb) of the flanking sequence on different chromosomes are similar, but restriction mapping studies of 150 individuals (ref. 6 and G.I.B. and J. Karam, unpublished results) indicated that a highly polymorphic region is located ~500 bp before the point where transcription of insulin mRNA begins[6]. Sixty-three per cent of non-diabetic caucasian individuals examined are heterozygous at this site, and there are two major and one minor class of alleles[6]. However, as there is heterogeneity within each class, there are many different alleles at this locus. Preliminary data also indicate that there may be racial differences in the frequency of alleles, that this polymorphism is inherited in a mendelian fashion in a four-generation pedigree and that the organization of the polymorphic region in DNA prepared from an insulin-secreting adenoma and white blood cells of the same individual is identical (G.I.B., unpublished). However, the molecular events which produce either this highly polymorphic region or one with similar properties that has been described at an unidentified locus[7], have not been determined.

Restriction mapping studies of the insulin gene region suggested that the restriction fragment length polymorphism is generated by the insertion–deletion of DNA sequences, so that fragments of different size are generated when DNA from a heterozygous individual is digested with selected restriction endonucleases. The insertions in this region are primarily of two size classes: 0–600 bp and 1,600–2,200 bp; restriction fragments possessing insertions of 600–1,600 bp are rarely observed. We have sequenced the corresponding polymorphic regions of two chromosomes to determine the basis for this length polymorphism. The sequence comparison indicated that the polymorphism is generated by variation in the redundancy of

Fig. 1 Sequence of the 5'-flanking region and first coding region (exon) of the human insulin gene. The sequence of the insulin gene region of allele 1 (recombinant λHi1[1,2,5]) was determined by the procedure of Maxam and Gilbert[26], including the modified G·A reaction described by Cooke *et al.*[27]. The TATAAA sequence (Hogness box) is underlined and the putative 5' end of the mRNA (capping site) indicated by an asterisk. The individual oligonucleotide units in the tandemly repeating array are separated. As described in the text, there are several ways to divide this region into oligonucleotide units. The sequence presented here is part of a 4,992-bp DNA segment which also includes the sequence of the insulin gene and 3'-flanking sequence. This complete sequence, with a list of all restriction sites, is available on request. The sequence includes three changes from that previously published[1] which corrects one clerical and two sequencing errors, but still does not completely agree with that determined by Ullrich *et al.*[5]. The sequences across the *Bam*HI and *Pst*I sites at positions 185 and 817, respectively, were not determined.

a family of G + C-rich oligonucleotides. This family of sequences is only tandemly repeated in this region of the human genome, and as the arrangement of members of this family differs in these two homologous chromosomal regions, this region also shows DNA sequence polymorphism. The highly variable structure of this region contrasts with adjacent regions which are characterized by conservation of size and nucleotide sequence.

Molecular basis for length polymorphism

Restriction mapping studies established that the highly polymorphic region was in a section of the 5'-flanking region of the gene between *Bgl*I and *Pvu*II sites located ~1,300 and 259 bp, respectively, before the insulin mRNA coding region[2,6]. The sequence between and flanking these restriction sites was determined for two allelic DNA segments. The 2,227-bp sequence in this region for allele 1, recombinant λHiI (refs 1, 2) (β (ref. 5)), is shown in Fig. 1. This is a portion of a 4,992-bp segment of known sequence which includes 2,185 bp of 5'-flanking sequence, 1,430 bp encoding insulin mRNA precursor and 1,367 bp of the 3' flanking region.

As we previously noted[1], the insulin gene has a high G+C content (64.8%) and this is maintained in the 5'-flanking region (67.8% G+C). Another unusual feature of the 5'-flanking region occurs in the region 363–846 bp (nucleotides 1,825–1,340, respectively, Fig. 1) before the putative capping site in that it consists of 34 tandem repeats of a family of G+C-rich 14–15-bp oligonucleotides. Other oligonucleotides, ⩾10 bp, are also repeated, both direct and inverted (rc), in this region (Table 1). The most interesting is the 15-bp sequence AGGGGAGATGGGCTC (at nucleotides 976 and 2,135 (Fig. 1)) which is directly repeated 350 and 312 bp, 5' and 3' respectively, on either side of the region of tandemly repeating oligonucleotides. This sequence is not present elsewhere in the 4,992-bp segment. The 15-bp repeated oligonucleotide at nucleotide 2,135 is located between the two putative transcription control sequences[8,9]: the TATAAA sequence (Hogness box), nucleotides 2,156–2,161 (Fig. 1), and the −75 to −90 region (remote control sequence), nucleotides 2,110–2,118. These two 15-bp sequences are 1,159 bp apart in this allele. Examination of the 2,185 bp of 5'-flanking sequence and 1,367 bp of 3'-flanking sequence for additional control sequences, TATA (Hogness box) and AATAAA (polyadenylation signal), showed that the only ones observed were those of the insulin gene. Thus, this sequence does not indicate the position of any adjacent genes nor the presence of any other insulin-like sequences. Moreover, we have not observed by hybridization any insulin-like sequences within 20 kb of the insulin gene. As we previously indicated[1], the sequence including the putative 5' end of insulin mRNA CAGCCCT (nucleotides, 2,185–2,191, Fig. 1) (the A is the residue which is capped), is tandemly repeated upstream at nucleotides 2,178–2,184 (Fig. 1). This sequence is also present within intervening sequence 1, coding region 3 and the region encoding the mature 3' end of the mRNA (CAG$\overset{*}{\mathrm{C}}$CCT) (the asterisk indicates the residue which is polyadenylated). Such repetition of the sequence in the regions encoding the 5' and 3' ends of the mature mRNA is thus far unique to the human insulin gene.

The 1,274-bp sequence in the 5'-flanking region of allele 2, recombinant λHi2 (refs 1, 2) (α (ref. 5)), was determined from a *Pst*I site corresponding to the *Pst*I site at nucleotide 817 of allele 1 (Fig. 1) to the *Pvu*II site at nucleotide 1,927. The sequences of the two alleles were identical at nucleotides 815–1,394 and 1,764–1,930, diverging in the region of the family of tandemly repeating G + C-rich oligonucleotides. There were 45 repeats in the region flanking allele 2. These 11 additional repeating units (158 bp) account for the size difference previously observed by restriction endonuclease mapping and DNA heteroduplex analysis of the two alleles[2]. Thus, variation in the redundancy of the oligonucleotide sequence is responsible for the differences in the length of homologous restriction fragments.

Organization and sequences of the repeating oligonucleotide family

Ten different oligonucleotide sequences have been observed among the 79 repeats analysed (Table 2). The frequency of each member of the family and the organization of the array were different within the two allelic chromosomal DNA segments (Table 2), the most frequent oligonucleotide (46.8%) being the 14-bp ACAGGGGTGTGGGG. (As there is no unit number of repetitions, the sequence description is somewhat arbitrary (Fig. 1).) This 14-bp sequence is also the consensus sequence for members of this family and changes have been observed at 8/14 positions, the most variable portion being that between

GGGGT and GGGG. Both nucleotide substitutions and single nucleotide insertions are observed: G → CC, G → C, GT → CCC. And in addition the boundaries of this region, 5'CTGGGG,ACAG3', are found in the 14-bp sequence.

Although the arrangement of the various oligonucleotide sequences within the polymorphic regions is different (Fig. 2*b*), the composition and order of the three units at the 5' boundary and the four units of the 3' boundary of this region are identical. Moreover, the variant sequence ACAGGGTCCTGGGG (in Table 2) is found only once in both arrays in this conserved 5' boundary region. These data suggest that the molecular processes which generate the divergence within this family operate on the central regions of the array.

Length variation of polymorphic forms

We have previously shown that the polymorphism exists in two major forms[6]. Approximately 75% of all the insulin gene regions analysed have a short polymorphic region (0–600 bp) and ~25% possess a longer polymorphic region (1,600–2,200 bp). Polymorphic regions of intermediate size are rarely observed (6/300 chromosomes examined). The two allelic DNA segments which we have sequenced are of the more frequent shorter form. As the length heterogeneity in this class is essentially due to variation in the number of oligonucleotide repeats, our previous data[6] can be reinterpreted. The shorter polymorphic region is composed of alleles with 26–63 repeating oligonucleotide units, with an average of 38 repeats.

We have examined the nature of the longer polymorphic form by hybridizing an *in vitro* labelled 879-bp *Pvu*II fragment of the flanking region of allele 2 (λHi2, the allelic DNA segment corresponding to the region at nucleotides 1,206–1,927, Fig. 1) to a *Sac*I digest of DNA of nine individuals, four of whom possessed both a short and a long polymorphic region (individuals 019, 025, 035 and 038, Fig. 2). This 879-bp *Pvu*II fragment included 45 repeating units of 641 bp, as well as 134 bp on the 5' end and 105 bp on the 3' end. We reasoned that if the length variation in the larger polymorphic region was due to this same repeating oligonucleotide, we should observe more intense hybridization to DNA fragments containing the longer polymorphic region.

There was more intense hybridization to the larger fragment in four individuals: 019, 025, 035 and 038 (Fig. 2). In contrast, a DNA fragment specific for the insulin gene, which included a 59-bp 5'-flanking sequence, 1,430-bp structurel region and 118-bp 3'-flanking sequence, hybridized with equal intensity to both DNA fragments (data not shown and Fig. 2C in ref. 6). Thus, this differential autoradiographic signal is not due to differential transfer or selective loss of DNA from the filter but is due at least in part to variation in the redundancy of this family of oligonucleotides. However, without cloning and sequencing the longer polymorphic allele or the rare intermediate form, we cannot exclude the possibility that another sequence in the ~100 bp on either side of the repeating oligonucleotides has not been selectively amplified. There are no other tandemly repeated sequences flanking the polymorphic region, so if additional sequence amplification occurred, it is of a non-repeated sequence. However, as we have defined the boundaries of the region of length variation for all forms, *Bgl*I and *Pvu*II sites at nucleotides 1,025 and 1,927 (Fig. 1), respectively[2,6], and more recently between *Pvu*II sites at 1,206 and 1,927 (unpublished)), we believe that the variation in the redundancy of this family of G+C-rich oligonucleotides accounts for all length variation. Thus, the longer polymorphic regions contain 141–209 repeats, with an average of 163. The rare intermediate forms possess ~80 repeats and the short form possesses ~40 repeats. The significance of the arithmetic progression in the number of repeats is unknown.

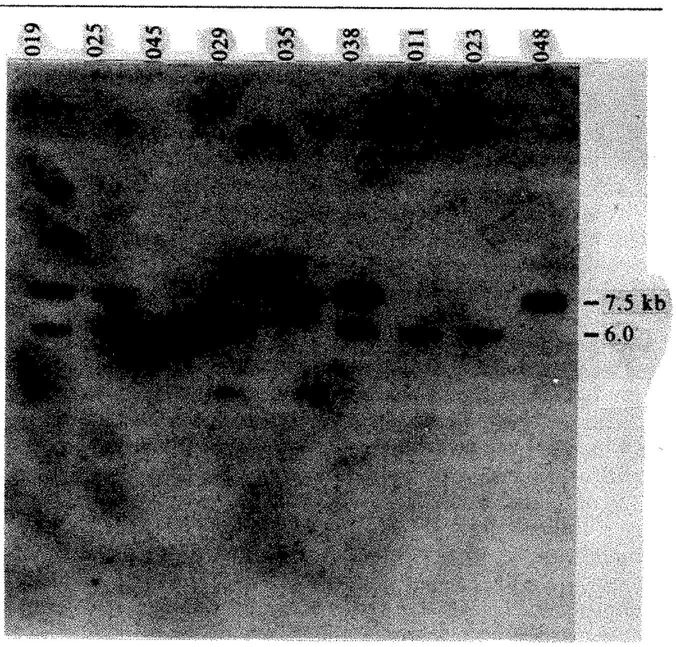

Fig. 2 Hybridization of a DNA fragment containing the region of tandemly repeating oligonucleotides to *Sac*I digests of human DNA. DNA was prepared from white blood cells, digested with *Sac*I, the fragments were separated by electrophoresis in a 1% agarose gel, transferred to nitrocellulose filters and hybridized as described previously[6]. Individuals are indicated by number above the autoradiogram and sizes of hybridizing fragments on the right.

Presence of the polymorphic region in the genome

We have been unable to detect additional regions of hybridization of the 879-bp *Pvu*II fragment to digests of genomic DNA (Fig. 2) or the ~45 kb of DNA sequence around and including the insulin gene (data now shown). Thus, the sequences within the 879-bp *Pvu*II fragment are restricted to the region flanking the 5' end of the insulin gene or at least they are not tandemly repeated elsewhere in the genome. This confirms our previous results[2]. The redundant oligonucleotide region is therefore a single copy sequence.

Comparison with the rat insulin I gene

We have examined the 5'-flanking region of the rat insulin I gene for a similar polymorphic region and have determined the sequence of this region of the gene from a *Pvu*II site 414 bp from the 5' end to the beginning of the mRNA coding region (Fig. 3). There were no tandemly repeating sequences. If such sequences exist they must be more than 414 bp from the 5' end of the coding region.

A comparison of the extended 5′-flanking sequences of the human and rat I insulin genes (Fig. 3) indicated that the homology is more extensive than suggested by the heteroduplex analysis[2]. In fact, interrupted regions of nucleotide sequence homology extend for ~365 bp from the structural portion of the gene, the homology apparently ending at or near the boundary of the polymorphic region of the human gene without being re-established on its other side. This nucleotide sequence conservation suggests that DNA sequences besides the TATAAA (Hogness box) sequence at −25 to −30 and the remote control sequence at −75 to −90 are involved in the regulation of insulin gene expression.

The regions of homology might represent points of interaction between the DNA and other regulatory molecules. Wu and Gilbert[10] have also suggested that additional sequences in the 5′-flanking region of the insulin gene may be involved in the regulation of insulin gene expression. They observed that a region of the rat insulin II gene, 250–300 bp upstream from the start of transcription, exhibits tissue-specific DNase sensitivity. Lomedico *et al.*[11] also observed that the homology between the rat insulin I and II genes included ~500 bp in the 5′-flanking region.

Discussion

The human insulin gene and its flanking regions exhibit conserved and highly variable sequences. Comparison of 2,357-bp segments from two chromosomes showed only four substitutions (4/2,357, 0.17%; this paper and ref. 5), all within the 1,430-bp portion encoding the mRNA precursor. The 5′-flanking region contains a section of extensive length and sequence heterogeneity which is generated by variation in the number and arrangement of members of a family of G + C-rich oligonucleotides whose consensus sequence is ACAGGGGTGTGGGG. This polymorphic region, although internally repetitious, is a single-copy structure. A comparison of the size of this region in individuals indicates that it can vary from 26 repeat units (364 bp) to 209 units (2,926 bp). The latter generates a DNA segment twice the size of the structural region (1,430 bp) of the human insulin gene. Moreover, the sequence polymorphism suggests that those alleles which cannot be distinguished by size may be distinguished by sequence.

Fig. 3 Sequence of the 5′ flanking region of the rat insulin gene and homology with the corresponding region of the human insulin gene. The rat I and human insulin gene sequences are indicated. The sequence of coding region 1 is also included. The putative 5′ end of the mRNA is A-414 in the rat I sequence and A-2186 in the human sequence. The isolation and characterization of the rat insulin I gene has been described[28]. The sequence was determined by the procedure of Maxam and Gilbert[10] as described in Fig. 1 legend. The human sequence is from Figure 1. Asterisks indicate homologous nucleotides. Gaps have been used to maximize homology.

Table 2 Organization of the oligonucleotide repeats in two allelic polymorphic regions

Upper panel, sequences of different oligonucleotides and the number of times (and percentage of all repeats) they occur in the two allelic DNA segments. Lower panel, arrangement of oligonucleotides in the polymorphic region. Each oligonucleotide sequence was assigned a letter as indicated in the upper panel.

The insulin polymorphic region can be distinguished from other regions of tandemly repeating oligonucleotides. Its unique chromosomal location and single copy nature distinguish it from the hexanucleotide sequences repeated at the ends of the fragmented, macronuclear DNA molecules of some protozoa[12,13], while its smaller size, greater internal redundancy and sequence simplicity distinguish it from the repeated sequences found at the *ori*-region of SV40 that have been implicated in the regulation of replication and perhaps transcription[14,15]. The insulin polymorphic region is similar to a region in the *Xenopus* 5S rRNA gene nontranscribed spacer which is also polymorphic and possess 2–12 copies of a 15-bp oligonucleotide[16] as well as to simple tandem repetitive sequences in the recombinational switch regions of immunoglobulin heavy chain genes[17]. The highly repetitive satellite DNAs present in eukaryotes are often composed of shorter repeated units (oligonucleotides)[18,19]. However, the insulin polymorphic region is only found at one site in the human genome, in contrast to those in the rRNA genes and satellite DNAs, which are present at many locations.

The sequence simplicity of the polymorphic region suggests that it could be involved in some recombinational process. However, the persistence of the bimodal distribution of insertion sizes[6] suggests that random crossing over within this array does not occur frequently because such exchanges would be expected to produce a unimodal distribution[20]. The insulin polymorphic region is more complex than the repeating T · G dinucleotide region in intervening sequence 2 of the human fetal γ-globin genes which has been implicated in gene conversion[21]. A similar region of repeating C · T dinucleotides has been observed in the sea urchin histone H2A and H1 spacer and it has been proposed that this region is involved in the maintenance of homogeneity of the histone gene repeating unit[22]. The sequence data on the regions flanking the insulin polymorphic region provide no evidence for gene conversion. There are 0/525 nucleotide differences on the 5′ side of the polymorphic region and 4/1,832 on the 3′ side (this paper and ref. 5).

The function of this polymorphic region is unknown. It could be intergenic or spacer DNA. Its location, within 363 bp or 2 nucleosomes from the coding region of the gene, adjacent to the putative transcription control region, suggests that the polymorphic region could have a role in the regulation of human insulin gene expression. However, this region does not seem to affect the transcription of the gene in cell-free extracts prepared from HeLa cells (G.I.B. and O. Laub, unpublished). If similar regions of tandemly repeating sequences have a general role in the regulation of insulin expression, they might be found flanking insulin genes of other species. Our sequence analysis of the rat insulin I gene indicated that it does not possess an homologous region in the same position, and that if present it is more than 50 bp upstream from the corresponding position of the human gene. However, this does not preclude a role for this region, as there are two non-allelic insulin genes in rats and only one in humans and most other organisms[23]. Thus, some elements of regulation of gene expression could be different.

The role of the additional, non-tandemly repeated sequences in the flanking region of the human gene is also unknown. The 15-bp sequence (Table 1) which is directly repeated ~325 bp on either side of the polymorphic region is particularly interesting as one member is located in the control region of the gene. It could be involved in the function of the polymorphic region or define some aspect of expression of the insulin gene. Though far and variably distant in the DNA sequence, these two sites could be contiguous in chromatin. Physical joining of these sites in chromatin could affect insulin gene transcription by regulating access of the RNA polymerase to the control regions.

The analysis of length variation in the 5′-flanking region of the human insulin gene indicated that 63% of the individuals examined were heterozygous at this site[6]. As this region also possesses DNA sequence polymorphism, the extent of heterozygosity was underestimated and it may be possible to distinguish the two parental alleles in most individuals by analysing this region for both length and sequence differences. This polymorphic region is a useful molecular marker for the insulin gene on the short arm of chromosome 11 (refs 4, 24) and may serve as marker for loci up to $10–20 \times 10^6$ bp distant[25].

We thank Dr D. N. Standring for useful discussions and Ms L. Spector and S. Bock for assistance in the preparation of this manuscript. This research was supported by an Elliott P. Joslin Research and Development Award of the American Diabetes Association, Inc., to G.I.B., and NIH grants to W.J.R.

Lysis gene expression of RNA phage MS2 depends on a frameshift during translation of the overlapping coat protein gene

Translation of the lysis cistron of MS2 RNA requires a frameshift of ribosomes reading the upstream coat protein mRNA. The out-of-phase fraction of ribosomes terminates at either one of two nonsense codons just preceding the lysis cistron. Termination is followed by initiation at the start codon of the lysis protein message.

THE group I single-stranded RNA bacteriophages (including MS2, f2, R17 and M12) contain the information for at least four proteins[1–5], the order of which is illustrated in Fig. 1. The figure shows that the newly characterized L gene, whose product is involved in lysis of the host, overlaps the coat and synthetase gene in the +1 reading frame. The complete primary sequence of MS2 RNA has been published previously[6].

The timing and efficiency of phage gene expression in the infected cell has been extensively reviewed for the three longer known genes[7]. As for the lysis gene, why has it evolved in its present position, where there is overlap with two other genes? In particular, in what way does this position relate to the level and time of expression? The L protein is made in small amounts and its appearance in the infected cell coincides with that of the coat protein[5]. A relationship between coat and L protein synthesis is suggested by the observation that phage coat ambers do not lyse their (non-permissive) host[8].

The availability of cloned MS2 DNA[9] allowed us to examine how the expression of the L gene is regulated. We used the recombinant DNA approach, which has several advantages over studies using normal phage infection: it allows the site-selected introduction of almost any kind of mutation and the expression of a single gene can be examined.

Our results indicate that the lysis cistron does not possess an independent entry site for ribosomes. Instead its translation depends on the readout of the coat gene. Ribosomes that experience a frameshift when reading the coat gene preceding the lysis cistron, terminate protein synthesis a few codons before

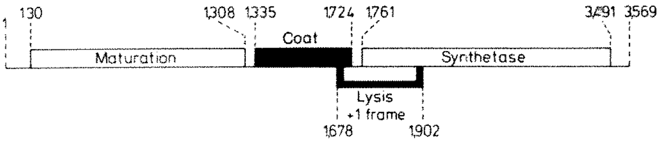

Fig. 1 Genetic map of the RNA phage MS2. Nucleotide numbers are taken from ref. 6. The reading frame of the lysis gene is +1 with respect to the coat and synthetase frame.

this gene due to the presence of two out-of-phase stop codons. Termination of protein synthesis at these positions elicits synthesis of the lysis protein.

Expression of the lysis gene in wild-type MS2 DNA subgenomic regions

In this study, selected regions of the MS2 genome were inserted into plasmid pPLa831, just downstream of the λ leftward promoter pL. The plasmid has been described in detail elsewhere[10]. The promoter pL is closed at 28 °C by a thermosensitive repressor encoded by the host chromosome. At 42 °C the repressor is unstable and the promoter is turned on.

The stringency of temperature control over the promoter in pPLa831-derived plasmids is demonstrated in Fig. 2. (Here, *Escherichia coli* strain M5219 (ref. 10) was transformed with pMS2 (Table 1) and labelled with radioactive amino acids.) At 28 °C, no MS2 coat protein is detected (Fig. 2, lanes 1 and 2), but at 42 °C the coat protein of the phage becomes the major product synthesized (lanes 3–7). Similarly, the presence of the almost complete MS2 DNA genome (nucleotides 103–3,569) in pPLa831 did not interfere with the growth of the transformed cells as long as transcription from pL was blocked by keeping the culture at 28 °C. However, if this particular clone (pMS23) was shifted to 42 °C, complete lysis was observed (Fig. 3*a* and Table 1). Apparently the L gene is expressed in the experimental conditions used. Evidence that cell lysis can indeed be ascribed to the presence of the L gene is provided by a clone containing pMS20. This plasmid carries a 58 nucleotide-long deletion in the L gene (Table 1). As shown in Fig. 3*a*, the deletion abolishes cell lysis, in agreement with the proposed genetic map.

To determine a possible contribution of the other gene products to cell lysis we deleted large parts of the maturation protein gene and the synthetase gene to obtain plasmid pMS16. Cells harbouring this plasmid still lyse on induction of the pL promoter (Fig. 3*a*). Thus neither the maturation (A) protein nor the synthetase appears necessary for cell lysis. The ability of plasmids to lyse the host cell is maintained up to a point where the whole A protein is removed (pMS17; Table 1).

L gene expression requires overlap of coat and L genes

When the MS2 DNA information in pMS17 was trimmed away further to give pMS1 (Table 1), there was no cell lysis at 42 °C (Fig. 3*b*). There are several possible explanations for this and we have considered the two that are more likely. (1) L protein synthesis is under translational polar control of the coat gene. In this case, ribosomes reading the coat message must open up the initiation region of the L cistron to allow independent initiation by another ribosome. The start region of the L cistron is thus thought to be inaccessible to ribosomes in the unperturbed mRNA. In ribosome binding experiments, this region of MS2 RNA has been found to be unprotected against RNase digestion[4,11]. (2) Absence of cell lysis in pMS1 clones could indicate that the coat protein itself is in some way required for cell lysis to occur—involvement of the coat protein has been suggested previously[8].

To test alternative (2), we modified pMS1 by inserting the MS2 DNA region specifying the coat protein behind the L gene, thus uncoupling the gene overlap. Clones carrying this new plasmid (pMS1.9) did not lyse on induction, although the presence of the MS2 coat protein was evident from protein gel analysis of the type shown in Fig. 2. This suggests that L protein synthesis depends on the native gene arrangement and supports a polar control mechanism. Further evidence for the involvement of translational polar control was provided by pMS25. Here we deleted the initiation region of the coat gene and the ability of this plasmid to induce cell lysis was lost (Table 1; and Fig. 3*b*). As before, lysis is not restored when the information for the coat protein is supplied behind the L gene (pMS25.9). Note that in pMS25 the 5′ context of the L gene is kept intact for over 300 nucleotides. This virtually excludes the possibility that the lack of mRNA translation is due to the deletion of translational start signals (in the conventional sense).

Efficiency of coat protein synthesis correlated with onset of cell lysis

During this study we obtained independent evidence that the translation of coat and L protein mRNA sequences is coupled; clones producing large amounts of coat protein also lysed quickly. In contrast, clones synthesizing small amounts of coat protein showed delayed lysis. Variations in coat gene expression can be obtained by varying the length of the MS2 DNA region proximal to the coat gene. For example, after induction of pMS2, coat protein comprised 30% of the newly synthesized proteins after 30 min, as opposed to <5% for pMS17. Cell lysis (as measured by the decrease in turbidity) began after 30 min for pMS2 and only after 75 min for pMS17. The data for several clones are summarized in Table 2. A positive correlation between the rate of MS2 coat protein synthesis and the onset of cell lysis is apparent. Such a relationship is consistent with a polar translational control mechanism.

Fine regulation of polar control

During phage infection, polar control of synthetase translation is observed in coat protein mutants that have a nonsense codon in the position of the sixth amino acid. The control is relieved when the stop codon is found further downstream at amino acid residue 50, 54 or 70 (ref. 12). Based on these data and the MS2 RNA secondary structure model, a molecular basis for this polarity has been proposed[13], the main feature of which is the base-pairing between the synthetase initiation region and a coat cistron coding sequence (see Fig. 4). Ribosomes passing this region are thought to expose the synthetase ribosomal binding site to allow independent initiation of protein synthesis. A similar situation may exist at the start of the L gene. Assuming the validity of the 'coat–lysis polarity control' one would expect that the L gene becomes readable once ribosomes pass over

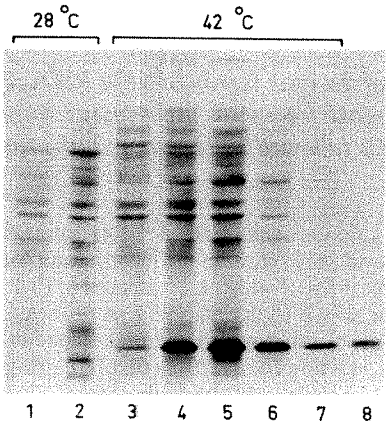

Fig. 2 Expression of MS2 DNA in cells transformed with pMS2. Cultures were grown to 0.2 A_{650}, then labelled with ^{14}C-amino acids for the time intervals indicated below. Proteins were analysed on polyacrylamide gels containing 0.1% SDS. Lanes 1, 2: pattern after labelling at 28 °C for 5–25 and 95–115 min, respectively. Lanes 3–7: labelling at 42 °C for 5–10, 5–25, 35–55, 65–85 and 95–115 min, respectively. Lane 8: *in vitro*-labelled MS2 coat protein.

Table 1 Host cell lysis by pPLa831-derived plasmids after induction at 42 °C

Plasmid no.	MS2 DNA inserted in pPLa831	Cell lysis after induction at 42°C	Schematic representation of MS2 genes present
pMS1	1,628-2,057	-	pMS1.9	1,628-2,057. 1,221-1,736	-	pMS2	103-2,057	+	pMS9	1,221-1,736	-	pMS12	1,221-2,057	+	pMS16	869-2,057	+	pMS17	1,305-2,057	+	pMS18	869-3,569	+	pMS20	869-2,057 (∇ 1,764-1,822)	-	pMS23	103-3,569	+	pMS25	869-2,057 (∇ 1,013-1,365)	-	pMS25.9	869-2,057 (∇ 1,013-1,365). 1,221-1,736	-		MS2 DNA inserted in pPLa932		
pMS32.00	1,221-2,057 1,628 1,629	+	
pMS32.04	1,221-2,057 (G.AAT.TAA.TTC.)	-	
pMS32.259	1,221-2,057 (∇ 1,369-1,628) GTC.GAA.ATT.C 1,369 1,629	+	
All nucleotide numbers refer to the primary structure of MS2 RNA (Fig. 1; ref. 6). MS2 DNA was inserted in pPLa831 according to standard procedures using either the *Eco*RI site, the *Bam*HI site or both. When the MS2 DNA region of interest did not contain a suitable site, *Eco*RI or *Bam*HI restriction site linker sequences were attached. MS2 DNA sites used were: *Eco*RI (103) (nucleotide number), *Pvu*II (869), *Sal*I (1,013), *Hae*III (1,221), *Xba*I (1,305), *Sal*I (1,366), *Eco*RI (1,628), *Hae*III (1,736), *Bam*HI (2,057). pPLa932 is identical to pPLa831 except that the *Eco*RI site was removed by cutting with *Eco*RI, filling in the single-stranded regions with DNA polymerase I (large fragment) and re-sealing with T4 DNA ligase. Thus, pMS32.00 is equivalent to pMS12 except for the *Eco*RI site in the vector. pMS32.04 was constructed by opening up the *Eco*RI site of pMS32.00 at position 1,628. The resulting sticky ends were filled with DNA polymerase I (large fragment) and the plasmid re-sealed with T4 DNA ligase. The new sequence around 1,628 is shown. The coat reading frame is indicated by dots. The construction of pMS32.259 is described in the text. The distance between the *Sal*I and *Eco*RI positions is 263 nucleotides. As 4 nucleotides are recovered by the action of the polymerase, the final deletion is 259 nucleotides. The reading frame is indicated by broken lines.

nucleotides 1,563–1,570. To test this, we introduced a UAA stop signal in the coat gene beyond this region, that is, at position 1,632. Surprisingly, cells harbouring this new plasmid, pMS32.04, did not lyse the host cell (Fig. 3*c*). The expression of the inserted MS2 DNA was apparent from the synthesis of a protein having the size of the expected coat protein ochre fragment (Fig. 6). The absence of lysis in clone pMS32.04 indicated that for L cistron translation to occur, ribosomes have to move beyond position 1,632 of the MS2 RNA sequence. To achieve this we again modified pMS32.00. The unique *Sal*I and *Eco*RI restriction sites, at positions 1,366 and 1,628 respectively, were used to delete this region of 263 nucleotides. The resulting staggered ends were filled in with DNA polymerase I (large fragment) and the plasmid re-sealed (pMS32.259). A consequence of the deletion was a shift to the +1 reading frame at the junction site. The +1 reading frame allows ribosomes that start at the coat cistron to proceed up to position 1,672, where they encounter an ochre stop codon, three nucleotides before the L cistron start (Fig. 4). Clones containing this plasmid (pMS32.259) lysed quickly on induction. Their growth curve was almost identical to that of pMS32.00 (not shown). From this we make two important conclusions. First, intact coat protein is not required *per se* for the synthesis or activity of the L protein. Second, ribosomes shifting their reading frame to +1 during coat cistron translation, so as to arrive at the ochre stop codon at nucleotide 1,672, trigger synthesis of the L protein.

Reading frameshifts in coat cistron promote synthesis of lysis protein

Results from clone pMS32.259 suggest that synthesis of the lysis protein from wild-type RNA may depend on a ribosomal frameshift to the +1 mode at the appropriate region. To explore this further, we constructed a collection of coat gene deletion mutants that potentially contain all three reading frames. Experimentally, pMS32.00 was opened at its unique *Eco*RI site and the linearized DNA treated with exonuclease *Bal*31 for 15, 30, 60 and 90 s, respectively. The reaction mixtures were pooled, the DNA ligated and used for transformation. Of 250 recombinants obtained, 60 were selected for further restriction analysis and lytic properties. The growth curves obtained were of three general types: quick lysis, delayed lysis and no lysis.

Nine clones, with the general nomenclature pMS32.*N*, where *N* is the number if nucleotides deleted, were selected for sequence analysis of the modified region (Table 3). Clones pMS32.16 and pMS32.28 change the coat reading frame to +1 at the junction. These clones lyse quickly, as does pMS32.259 (Fig. 5). There are three more clones in which the coat reading frame is forced to +1 by the deletion. In two of these, pMS32.55 and pMS32.85, the onset of lysis was delayed with respect to the previous +1 frameshift mutants (Fig. 5), which may be related to deletions in the Shine–Dalgarno sequence, AGGU, around position 1,664 (Table 3). The last +1 frameshift clone is pMS32.88, which lacks the nonsense codon at position 1,672 together with the first 12 codons of the L gene, thus the absence of lysis was not unexpected. The coat protein ochre fragments or fusion peptides coded for by the respective plasmids can be detected in minicells (for examples see Fig. 6). In two clones, pMS32.17 and pMS32.50, the deletion leads to a −1 shift in the reading frame. In pMS32.17 this shift caused ribosomes to terminate at ochre stop codon 1,652. Evidently, termination at this position also allowed translation of the L gene mRNA, albeit with a lower frequency as judged by the delayed lysis of this clone (Fig. 5). Clone pMS32.50 did not lyse but in this case the −1 frame stop codon at position 1,652 had been deleted. It seems, therefore, that the frameshift itself was not signalling lysis protein expression but rather its inevitable consequence, chain termination.

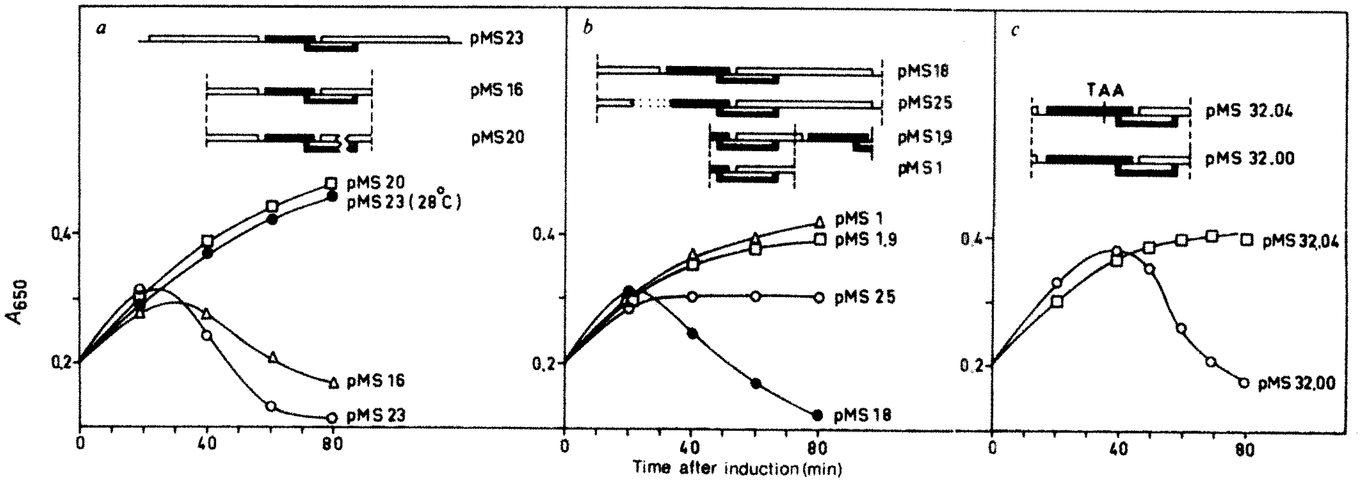

Fig. 3 Lytic properties of clones containing various regions of MS2 DNA inserted in pPLa831 or pPLa932 (see Table 1). Cells were grown at 28 °C to an A_{650} of 0.2. Growth was then continued at 42 °C (except where indicated). MS2 DNA regions present are shown schematically at the top.

Deletions in coat gene that do not change the reading frame

Two clones, pMS32.27 and pMS32.3, have deletions that do not change the reading frame. These two plasmids have lost the property to lyse their host (Fig. 5), which supports the view that expression of the L gene requires a ribosomal frameshift.

Obviously the absence of lysis in 0 frame coat mutants poses a problem as the wild-type sequence is read by definition in the zero frame. It seems, therefore, that the deletion decreases the chances that a phase shift occurs. The frameshift in wild-type MS2 RNA could arise in two ways: (1) interference of coat protein, bound to the start of the synthetase, with the movement of the reading ribosome. Although this involves an unknown mechanism it is formally correct, as the absence of wild-type coat protein distinguishes the 0 frame deletion mutants from the wild type. However, there is one argument that weakens this possibility. We have constructed a 0 frame mutant that carries a deletion of 18 nucleotides at the 5′ end of the coat gene (∇1,365–1,384), which is still able to lyse its host. (2) Frameshift is induced by a specific RNA structure present in or around the deleted region at position 1,628. An interesting sequence CAAUUUUC, present around position 1,620, or its immediate neighbourhood, was found to induce a +1 frameshift in yeast mitochondria[14]. However, the limited number of deletion mutants analysed does not allow a strong conclusion to be made concerning the significance of the 8-base homology. With regard to this, note that a +1 frameshift was observed *in vivo* between nucleotides 1,675 and 1,724, which does not include this particular nucleotide sequence[5].

Translation of overlapping messages

As initiation of protein synthesis is slow compared with elongation, the independent translation of overlapping messages presents a general problem. Frequent readout of the upstream messenger (coat cistron) seems bound to interfere with independent initiation at the downstream message (L gene). At first glance one would therefore expect a regulatory mechanism

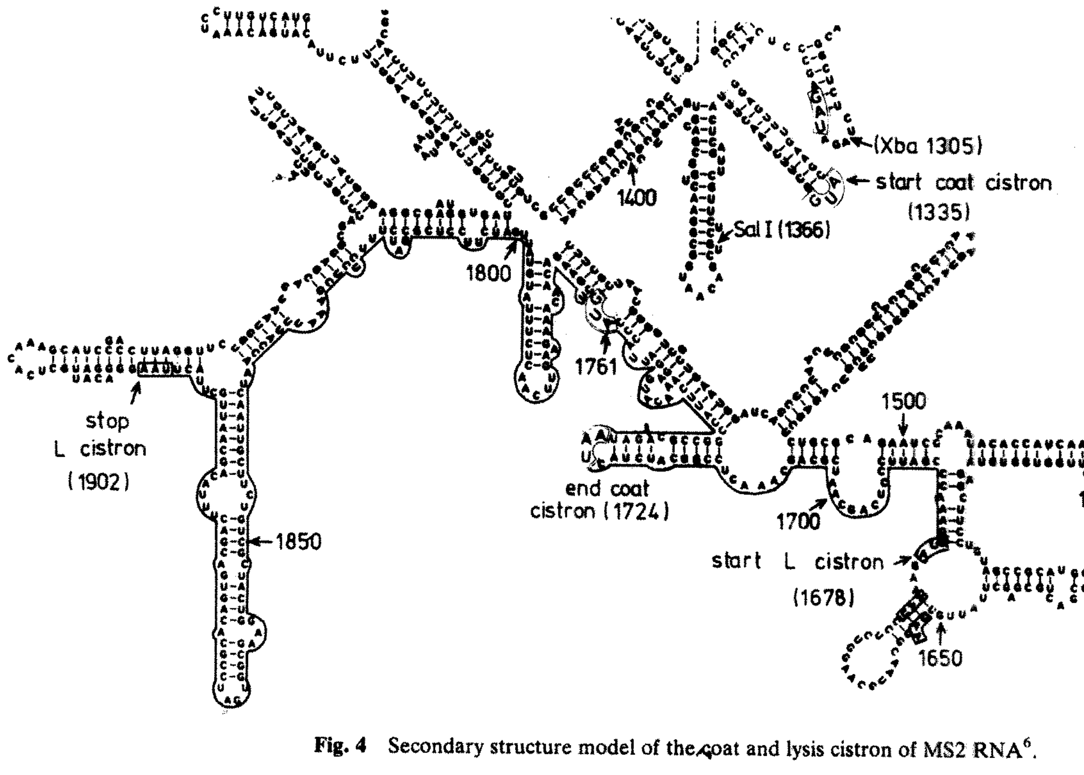

Fig. 4 Secondary structure model of the coat and lysis cistron of MS2 RNA[6].

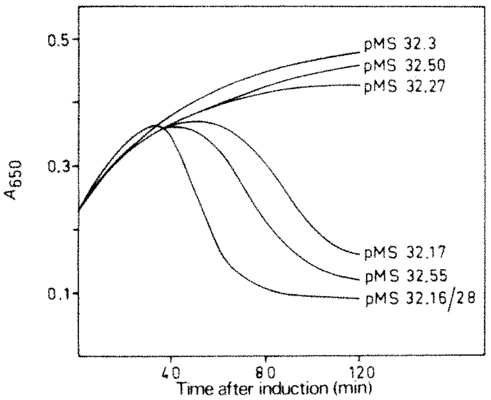

Fig. 5 Effect on cell lysis of reading frameshifts in the coat protein cistron. The MS2 DNA present in the plasmids is shown in Table 3. Growth of the cultures was as described in Fig. 3 legend.

that promotes expression of the downstream gene by interfering with the translational start at the upstream message to clear the template of ribosomes. However, such a solution seems impossible or inappropriate in this case. Instead, phage MS2 has solved the expression of the overlapping genes in an extraordinary way. The clones of the pMS32.*N* series lead us to conclude that translation of the L cistron relies on the fraction of the ribosomes that arrives out of frame at the beginning of this gene. The positions of two ochre codons, respectively in the +1 and −1 frame, just before the L cistron, elicits peptide chain termination, which in turn allows the reinitiation at the start of the L message, a region otherwise inaccessible to ribosomes. It is unlikely that ribosomes leave the RNA at this point as this would again create the problem of independent initiation.

The phenomenon of reinitiation has been recognized for some time in the *lac*I, *lac*Z and the bacteriophage T4 rIIB RNA. It may occur after a polypeptide chain is prematurely terminated at the site of a nonsense mutation[15-18]. Although several translational restarts have been analysed at the nucleotide level, it is not fully understood which features transform a sequence into a potential reinitiation site[19,20]. The presence of a Shine–Dalgarno region seems dispensable for a translational restart[20]. This agrees with the ability of our clones pMS32.55 and pMS32.85, which lack all or part of this region, to express the L gene, although expression is less efficient than when the Shine–Dalgarno sequence is still present (pMS32.16 and pMS32.28).

It is interesting to note that the phage may be able to adjust the level of L gene expression by varying the distance between the AUG start codon and the preceding stop codon. This distance is 47, 23 and 3 nucleotides in pMS32.04, the −1 and the +1 frameshift mutants, respectively. The +1 frameshift mutant lyses quickly, the −1 slowly and pMS32.04 not at all. Although these represent only three cases, we suggest that the shorter the distance between termination and initiation codons, the higher the probability for reinitiation. The present data do not tell us if both or one particular phase shift operates *in vivo*. A recent analysis[21] using *in vitro* translation of MS2 RNA seems to argue for a −1 phase shift in the region of interest. The occurrence of a frameshift polypeptide (peptide 9) terminating at position 1,652 has been reported elsewhere[21].

Table 2 Relationship between rate of MS2 coat protein synthesis and onset of cell lysis in four recombinants

Plasmid no.	MS2 coat protein present 30 min after induction at 42 °C (% of newly synthesized total protein)	Onset of lysis (min)
pMS2	30	30
pMS16	13	35
pMS12	6	40
pMS17	3	75

The relative amount of newly synthesized MS2 coat protein is calculated from protein separation on polyacrylamide gels (see Fig. 2). The coat protein is the major band in most clones and is identified by co-migration with *in vitro*-labelled MS2 coat protein extracted from the phage.

Translational fidelity and expression of the lysis gene

The frameshift model presented here predicts that ribosomes which exhibit extreme fidelity in translation will not (or only barely) synthesize the L protein. This point is implicit in the recent observation of De Mars Cody and Conway[22], that on infection of a particular streptomycin-resistant strain with wild-type f2 phage, virus particles accumulate inside the cell but no lysis follows. Ribosomes from streptomycin-resistant bacteria have a decreased error frequency, both with respect to mis-sense and frameshift[23].

Analogy with ΦX174 and G4?

Whether this model can be applied to other overlapping genes is uncertain. However, note a peculiar similarity between the overlap region in MS2 and that at genes A and B in the DNA

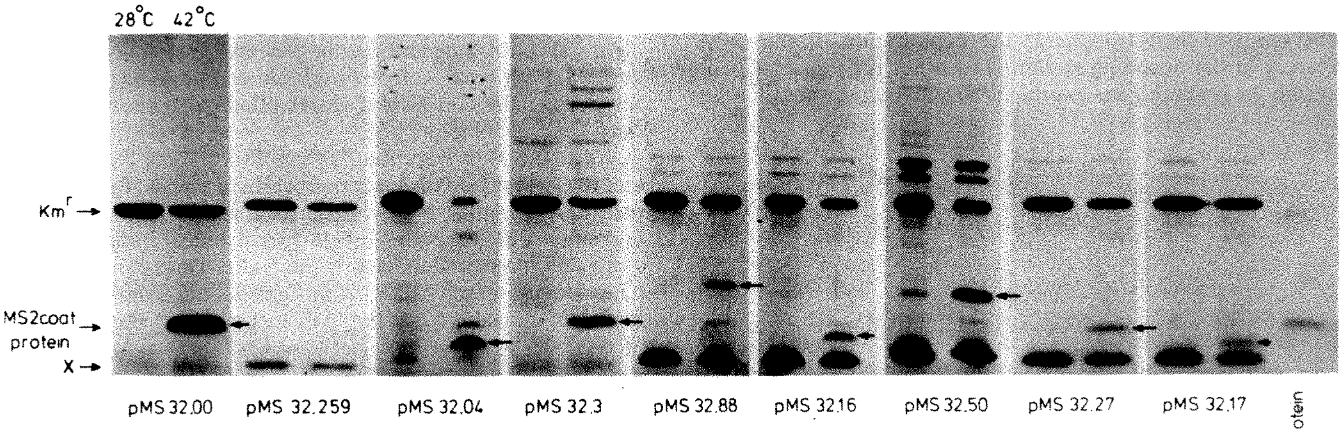

Fig. 6 Proteins synthesized in minicells carrying the indicated plasmids. For each plasmid the protein pattern before (left lane) and after (right lane) induction of the pL promoter is shown. The DNA sequence of pMS32.04, pMS32.16 and pMS32.17 predicts the formation of coat protein nonsense fragments of slightly different sizes. pMS32.50 and pMS32.88 give elongated proteins which, according to the DNA sequence, arise from fusion between the N-terminal region of the coat protein and a C-terminal part derived from a −1 frame (pMS32.50) or from the lysis protein (pMS32.88). Band X derives from a (stable) host mRNA. pMS32.3 and pMS32.27 are expected to yield MS2 coat protein lacking 1 and 9 amino acids, respectively. The protein formed in pMS32.3 cross-reacted with antiserum against MS2 coat protein. The lysis protein is not visible in any of the gels—this is possibly due to the very low level of synthesis of the protein. Translation from the start of the synthetase cistron produced a small amount of fusion protein running at the position of the coat protein (see for example pMS32.88). Arrows facing left indicate the MS2 coat protein or nonsense fragments, and the fusion proteins derived from it.

pMS32.3 was constructed by opening the unique *Eco*RI site of pMS32.00 at position 1,628. The linearized DNA was treated with T4 DNA polymerase and re-sealed with T4 DNA ligase. The other plasmids were constructed by treatment of pMS32.00 with the enzyme *Bal*31 as described in the text. All sequences were determined by the procedure described elsewhere[25]. 0, +1 and −1 in the deleted sequence refer to the change in reading frame at the junction. Stop codons are boxed. In pMS32.*N*, *N* indicates the number of nucleotides deleted. The position of the deleted nucleotides is shown.

phages ΦX174 and G4 (Fig. 7). Strikingly, the nucleotide indicated by an arrow in the out-of-phase ochre codon of ΦX174 is the third base of a codon specifying alanine, thus any other base would do. The corresponding U in G4 specifies asparagine, thus a C here would not change the meaning of the codon. Statistically, the chance of finding a U in the marked position in both phages is thus 1 in 8, if the only purpose is to specify the particular amino acids. This suggests that the U is there to introduce a stop codon.

Why gene overlap?

The design adopted by the phage to control and express the L gene has two aspects. One is the exploitation of the noise inherent in the decoding system. The other is the use of gene overlap. In general, gene overlap is considered as a solution for storing as much information as possible in a limited amount of RNA or DNA. It seems that another aspect of the overlap may be equally important: it allows and enforces the extreme coupling of expression of two genes that may be difficult or impossible to realize were the genes separated. For example, the chosen design guarantees that there will not be lysis of the host unless enough coat protein has been made, that is, until the infection has proven successful[24]. The use of the phase shift siphons off a very small fraction of the ribosomes destined for L protein synthesis. This, together with the position(s) of the nonsense codon(s), sets the balance between the amount of coat and L proteins needed.

The exploitation of reading frame errors represents a novel means of controlling and coupling the expression of overlapping genes. If such errors can be programmed into the base sequence this permits the synthesis of a large number of different proteins from a single template.

We thank Ben Berkhout, Johan Twilt, Kees Ravensbergen and Koos Van der Plas for construction of clones, Rein Dijkema for introducing us to the Maxam–Gilbert sequence technique and Hanny Bakker-Steeneveld for technical assistance. This work was sponsored in part by the Netherlands Foundation for Chemical Research (SON) with financial aid from the Netherlands Organization for the Advancement of Pure Research (ZWO).

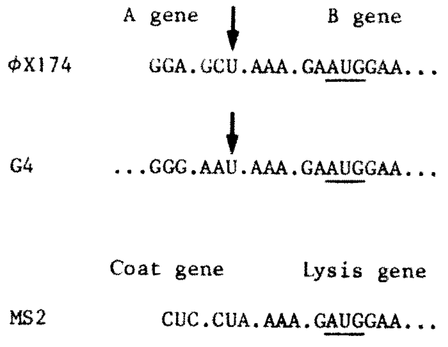

Fig. 7 Nucleotide sequences at the A/B gene overlap of phage ΦX174 and G4. The marked U is nucleotide 5,058 of ΦX174 (ref. 26) and 1,270 of the G4 sequence (ref. 27). Dots indicate the reading frame of the A gene. The coat–lysis overlap of MS2 is given for comparison.

Particle acceleration at planetary bow shock waves

M. M. Hoppe & C. T. Russell

Institute of Geophysics and Planetary Physics, University of California, Los Angeles, California 90024, USA

We can extend our understanding of collisionless shocks by comparing their behaviour in a variety of plasma conditions at several different planets. One property of such shocks is the occurrence of upstream magnetohydrodynamic waves associated with particle beams accelerated at these shocks, and flowing back towards the Sun[1]. We report here observations of one of these classes of wave at Mercury, Venus, Earth and Jupiter. First, we show that the empirical relationship between the interplanetary field strength and the frequency of the waves in the observer's rest frame, derived originally from ground-based pulsation studies, and later, *in situ*, is approximately true at all the planets. Second, the observed frequencies are consistent with resonance with beams of ions of essentially the same energy at each of the planets. This observation is consistent with Sonnerup's[2] geometrical model of ion reflection at collisionless shocks. The universality of this ion acceleration mechanism in the Solar System suggests that like acceleration occurs in similar astrophysical systems outside our Solar System and thus may provide a source of acceleration for cosmic rays.

One characteristic feature of the solar wind interaction with the planets is the creation of an upstream bow shock, formed when the supersonic solar wind encounters the planetary atmosphere or magnetic field. Such shocks have been seen at all the planets so far probed by interplanetary spacecraft, and their general character is similar in many ways to that of Earth's bow shock. However, certain facets of shock structure *per se*, such as the associated plasma wave spectra[3] and the magnetic field overshoot[4], do vary between planets. These changes are generally consistent with the evolution of solar wind parameters with heliocentric distance.

We present a complementary comparative study of planetary foreshocks, those regions upstream of, but magnetically connected to, the bow shocks. The varieties of reflected particles and associated waves characteristic of this region at the Earth have been studied in some detail[5]. We focus here on the large-amplitude ($\Delta B/B \sim 1$), low-frequency ($\sim$0.03 Hz) waves and the associated backstreaming ion populations. We now briefly review results of the terrestrial work which are pertinent to the current study and compare them with studies of the upstream regions of Mercury, Venus and Jupiter.

We use primarily magnetic field data because the plasma analysers onboard extraterrestrial missions tend to be configured to measure the solar wind and are not in general appropriate instruments for characterizing the lower-density reflected particles. We focus on the large-amplitude low-frequency waves which have been documented in the upstream regions of Mercury, Venus, Earth and Jupiter, and studied in depth at the Earth[6,7]. It seems likely that these waves are generated through cyclotron resonance with beams of reflected ions[8], although theory does not yet reproduce all the features of the observations[9]. These waves have been of interest for some time, partially because of their role in the foreshock structure, but also because of their apparent connection with geomagnetic pulsations of the same frequency.

The relationships between upstream conditions and pulsation character have been investigated on the hypothesis that the upstream waves may be the ultimate source of at least some classes of pulsations. A linear relationship between pulsation frequency and the magnitude of interplanetary magnetic field has been found[10,11]. Russell and Hoppe[12] recently verified that the same relationship that holds for ground data also holds for the upstream waves. We have found that this same relationship is maintained to a remarkable degree over the orders of magnitude differences in wave frequency and field strength observed during the various planetary encounters. This is shown in Fig. 1 where the frequencies of the upstream waves observed at the different planets are plotted as a function of the associated magnetic field strengths. Data for Mercury represent Fairfield and Behannon's[13] estimate of 5–10 s periods for the 'low-frequency' waves encountered by Mariner 10 on its outbound pass. The Venus data were obtained from the Pioneer Venus magnetometer. The Earth data are from ref. 12 and the two points from Jupiter represent intervals of upstream wave activity, one observed by Pioneer 10 (ref. 14), the other by Voyager 2. The straight line is the empirical relationship between wave frequency and field magnitude found at Earth[12]. Points for all the planets clearly fall along the same linear trend.

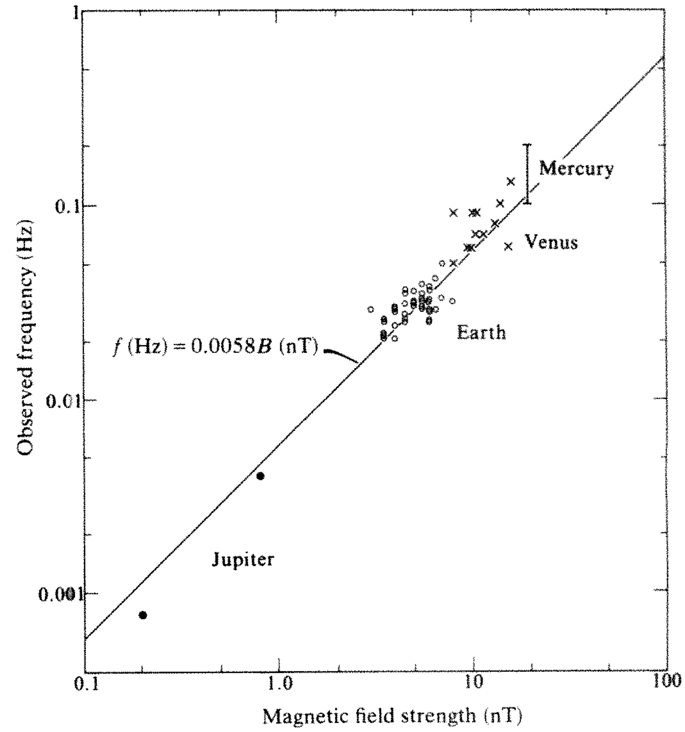

Fig. 1 Upstream wave frequency as observed in the spacecraft frame (f_{obs}) of reference as a function of ambient magnetic field strength.

0028-0836/82/010041—02$01.00

Table 1 Observed and rest-frame frequencies and resonant velocities

Planet	f' (Hz)	f_0/f_{ci}	v_r/v_{sw}
Mercury	0.1–0.2	0.09–0.17	1.2–2.2
Venus	0.06–0.13	0.064, 0.074	1.7, 1.9
Earth	0.02–0.04	0.03–0.08	2.5±0.3
Jupiter	0.0008(P)	0.06	2.3
	0.003(V)	0.02	2.1

Plasma data for Mercury from ref. 21, for Venus from Barnes (personal communication), for Earth from the Los Alamos ISEE team (personal communication) and for the Voyager Jupiter encounter (V) from the MIT plasma group (personal communication). Typical terrestrial values were scaled to provide estimates for the Pioneer Jupiter encounter (P).

This relationship can be understood as a combined effect of ion resonance and Doppler shifting, assuming that the waves are in each case low-frequency magnetosonic waves similar to those observed at the Earth. The terrestrial waves, which are a characteristic feature of the foreshock region, have long been thought to result from instability of ion beams reflected back along the IMF by the bow shock[8,15], although resonance with relativistic electrons has also been recently suggested as a source of the jovian waves[14]. The terrestrial waves are, however, very closely linked with upstream ion distributions[16] and spacecraft studies[17] have demonstrated that their properties are generally consistent with an ion beam generation mechanism. Specifically, it was shown that the terrestrial upstream waves are indeed magnetosonic waves with rest frame frequencies (f_0) of the order of 0.1 the local proton cyclotron frequency (f_{ci}). Because of Doppler shift effects this identification required the use of two point measurements, which for the terrestrial case were provided by the dual ISEE 1 and 2 spacecraft. One cannot ordinarily determine a wave's rest frame frequency using data from a single satellite. This is because even given the observed frequency (f'), solar wind velocity ($\mathbf{v}_{sw}$) and wave propagation direction $\hat{\mathbf{k}}$, there remain two unknowns, the rest frame frequency (f_0) and wavelength (λ) in the Doppler shift equation:

$$f' = f_0 + \frac{\mathbf{v}_{sw} \cdot \hat{\mathbf{k}}}{\lambda} \tag{1}$$

The number of unknowns can be reduced if we assume that the upstream waves at the extraterrestrial planets have rest frame frequencies of the same order as the terrestrial waves, $f_0 \leqslant 0.1 f_{ci}$. Waves in these low-frequency ranges have phase velocities very close to the Alfvén speed, $v_A = B^2/(4\pi n)^{1/2}$, where B is the magnetic field strength and n is the plasma density. Using this fact allows us to substitute $f_0 v_A = \lambda$ for λ equation (1). We can solve for f_0 in terms of the measured parameters f', v_{sw}, k, B and n:

$$f_0 = f' \Big/ \left(1 + \frac{\mathbf{v}_{sw} \cdot \hat{\mathbf{k}}}{B/(4\pi n)^{1/2}}\right) \tag{2}$$

Rest frame frequencies were estimated using this approach for all observations for which solar wind data were available, and wave propagation directions were determined through minimum variance analysis when possible. The 180° ambiguity which results in minimum variance analysis may be resolved by assuming the waves at Mercury, Venus and Jupiter are attempting to propagate upstream, as has been demonstrated to be the case at Earth. The angle between $\mathbf{v}_{sw}$ and $\hat{\mathbf{k}}$ was determined by minimum variance analysis of the Mercury, Earth and Voyager Jupiter data, was estimated from the average field orientation for Pioneer 10, and was assumed to have the same average value (35°) at Venus. Table 1 summarizes rest frame frequencies estimated in this way, normalized to the local proton cyclotron frequency. Estimated rest frame frequencies are of the same order at each planet, averaging about $0.07 f_{ci}$.

Having found results consistent with the hypothesis that the waves are in each case low-frequency magnetosonic waves, we can estimate the proton beam velocities required to generate waves of the observed frequencies. This was done by substituting calculated rest frame frequencies into the formula for the resonant velocity (v_r) of protons interacting with a magnetosonic mode wave[18]:

$$\frac{v_r}{V_A} = \frac{(1 + f_0/f_{ci})^{3/2}}{f_0/f_{ci}} \tag{3}$$

Calculated resonant velocities normalized by the ambient solar wind speeds are also presented in Table 1. Note that the resonant velocity given is the velocity parallel to the magnetic field relative to the component of the solar wind velocity along the field whereas most measurements are of total energy of the particles in the shock frame of reference. The beam energies are remarkably similar in all four cases, suggesting that essentially the same mechanism operates at each bow shock.

The consistency of the relationship between the observed wave frequencies and the magnetic field strength at the various planets derives from this equivalence of the source beam energies. In fact, taking a value of 2 for v_r/v_{sw}, solving for f_0 using equation (3) and substituting this value of f_0 into equation (2) using a nominal $\cos\theta_{kx} = -0.8$ yields the relationship f' (Hz) = 0.006 B (nT), which is in excellent agreement with the empirically determined relationship. Furthermore, the similarity of the inferred beam energies argues that the magnitude of bow shock acceleration must be relatively constant despite differences in shock size and structure. This similarity is consistent with Sonnerup's description of bow shock acceleration through particle displacement along the interplanetary electric field during the reflection process. In this description, which appears to predict accurately reflected beam energies at Earth[19], shock structure and strength have no influence and the amount of ion energization is determined strictly by geometrical effects. On the other hand, it is intriguing to see the smallest energies associated with the small relatively weak bow shock of Venus[20]. In any case, whatever the particle acceleration mechanism, the analysis presented here suggests that ion acceleration is a characteristic feature of planetary bow shocks and furthermore that reflected particle energies are of the same order regardless of shock scale size or structure.

Mariner 10 magnetic field data for Mercury and Voyager magnetic field data for Jupiter were obtained from NSSDC. This work was supported by NASA through contracts NAS 5-25772 and NGL 5-007-190.

Organic and inorganic interpretations of the martian UV–IR reflectance spectrum

Kevin D. Pang*, Sandy F. S. Chun†, Joseph M. Ajello*, Zhao Nansheng‡, & Liang Minji§

* Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109, USA
† School of Medicine, University of California, San Francisco, California 94143, USA
‡ Beijing Planetarium, China
§ Beijing Glass Institute, China

Although some data from the Viking Lander biology experiments can be interpreted as indicative of biological activity, the existence of organisms in the martian soil samples is considered unlikely because of the non-detection of organic compounds in the sample[1]. Viking gas chromatography–mass spectrometer analysis detected no organic molecules above a concentration of parts per 10^9 (ref. 2). We consider here why no organic molecules were detected at the landing sites, whether the sterility of the two sites is representative of the entire planet and if there are locations on Mars more conducive to the formation and preservation of organics. We first simulate the destruction of organic compounds in Mars-like laboratory conditions, and then examine whether the destructive mechanism would operate planetwide; and second re-examine UV and IR reflectance spectra of Mars for any evidence of organic molecules, and in doing so set an upper limit on the organic carbon content of average martian soil. The results reveal that the average martian soil is organic-poor and makes an unfavourable habitat for life forms based on carbon chemistry. There is no reason to believe that organic molecules are preferentially preserved anywhere on the planet.

Recent observations of the outer Solar System by ground-based and spacecraft UV–IR spectroscopy show an abundance of organic compounds, existing as atmospheric gases and imbedded in carbonaceous chondrites. Because of its proximity to the outer Solar System, Mars should have received a large infall of carbonaceous meteorites[3,4]. The fact that Viking found no organics at the landing sites means that a very efficient process must be operating on Mars to destroy the organic molecules.

Chun *et al.*[3,4] proposed a mechanism for the destruction of organics on Mars: UV-stimulated catalytic oxidation. The degradation process from complex organic ultimately into inorganic compounds is:

$$\begin{array}{c}\text{Complex}\\ \text{organic}\\ \text{compounds}\\ O_2\end{array} \xrightarrow[\text{TiO}_2]{h\nu} \begin{array}{c}\text{Simple}\\ \text{organic}\\ \text{compounds}\\ O_2\end{array} \xrightarrow[\text{TiO}_2]{h\nu} \begin{array}{c}\text{Inorganic}\\ \text{compounds}\end{array}$$

In a controlled laboratory experiment, powders of Murchison meteorite (C2), rich in organics, and TiO_2 were degassed in Pyrex flasks. The flasks were filled with oxygen at approximately martian surface partial pressure, 0.1 torr. These flasks were then irradiated with UV-visible light. Hard UV light that may cause photolysis was first filtered out. The flasks were rotated on a turning wheel to keep the powder constantly agitated, and inhomogeneities in the radiation field averaged out. The flasks were examined for changes in gaseous composition using a mass spectrometer. Samples of the powder were pyrolysed and analysed with a mass spectrometer. According to our proposed mechanism, an evolution of CO_2 in the flasks, and/or a change in distribution of masses from high to low molecular weights in the solids would mean that UV-stimulated catalytic oxidation of organic compounds has taken place.

After irradiation for 4 days a copious supply of CO_2 was observed in flasks where all three ingredients, O_2, TiO_2 and carbonaceous chondrite, were present. The evolution of CO_2 was accompanied by a decrease in O_2 abundance. In flasks where all ingredients, except TiO_2 were present a small but detectable reaction took place. In flasks where all ingredients except O_2 were present, or where the carbonaceous chondrite was replaced by basalt, there was no evolution of CO_2. Also no reaction was observed in flasks with all ingredients present but kept in the dark.

We interpret the results of the controlled experiment to mean that organic compounds in the carbonaceous chondrite are photocatalytically oxidized. Activation energy, provided by energetic photons, is required for the reaction to take place. A catalyst, TiO_2, speeds up the reaction, but is not essential.

Mass spectra of pyrolysed solid samples were difficult to interpret due to the vast number of peaks present. Attempts to identify and trace the breakdown of high-molecular-weight compounds, such as undecane (abundant in C2), into low-molecular-weight compounds, such as acetone (a product generally observed from photocatalytic oxidation of alkanes), were not successful due to obscuration by fragments from the breakdown of many other organic compounds. Instead of trying to trace the breakdown of a mixture of organic compounds present in the carbonaceous chondrite, we decided to trace the breakdown of one compound at a time. An example is the breakdown of naphthalene, an aromatic compound. The naphthalene sample was prepared and irradiated along with O_2 and TiO_2 as its carbonaceous chondrite counterpart. The evolution of CO_2 was again observed, accompanied by the appearance of

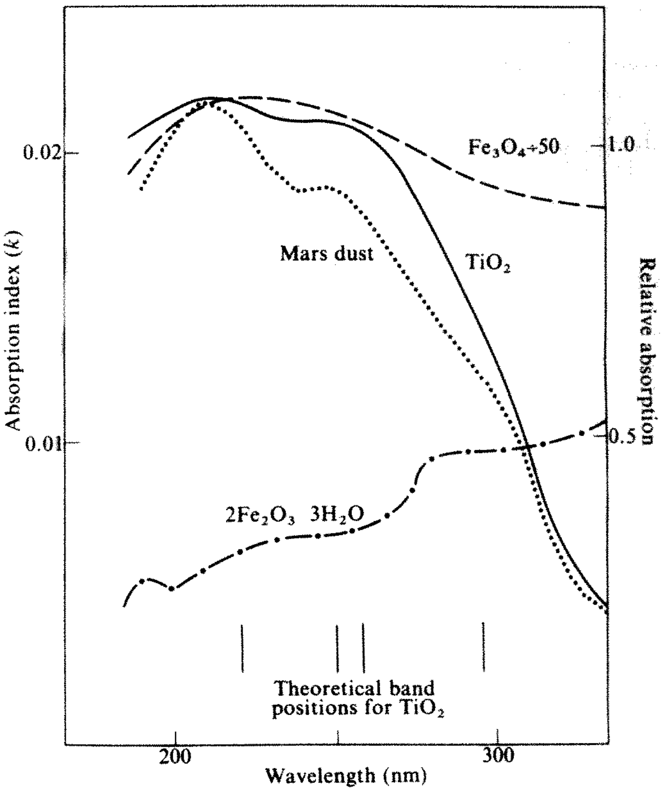

Fig. 1 Dotted curve indicates the absorption index *k* of martian dust (ref. 13). Solid curve is the relative absorption of anatase (an allotrope of TiO_2), normalized to the peak of Mars dust (measured by Zhao and Liang at the Beijing Glass Institute). Molecular orbital calculations for TiO_2 predict bands at the wavelengths indicated by tick marks (ref. 21). Data for magnetite (dashed curve) and limonite (dot-dashed curve) are from refs 23 and 24, respectively.

0028-0836/82/010043—04$01.00

simple organic compounds such as methane. We conclude that the naphthalene has broken down into simpler compounds.

Recently Sancier and Wise[5] found that photocatalytic oxidation is responsible for the degradation of organic compounds in terrestrial sand dunes. The catalyst for the sunlight-assisted reaction can be ordinary sand particles.

Whereas all conditions required for the photocatalytic oxidation of organic compounds: O_2 (ref. 6), sand (the dunes in Viking Lander pictures are evidence), and UV irradiation (as indicated by the darkening of UV-sensitive chips mounted on the Viking Landers, ref. 7) are present at the Viking landing sites, we conclude that the proposed mechanism operates at least at these two locations. To extrapolate this finding to the rest of the planet we need to examine conditions elsewhere to see if the requirements for photocatalytic oxidation are also satisfied.

The polar regions of Mars have been suggested as the most favourable sites for preservation of organics but there is no basis for this speculation. First, Mariner 9 UV spectrometer observations showed that solar radiation of wavelengths as short as 200 nm easily penetrates the martian atmosphere down to the polar cap[8]. Second, sand grains exist in great abundance in the polar regions on Mars—in dunes and laminated between condensates[9]. Third, ozone is found in the martian polar atmosphere, although not in a concentration to attenuate the solar UV significantly[10]. The presence of O_3 requires that O_2 be there also. Therefore, all conditions necessary for the photocatalytic oxidation of organics—UV radiation, oxygen, and sand—are present in the polar regions of Mars, and the destruction of any organic molecules on the polar caps seems almost certain.

Theoretical atmospheric modelling by Hunten[11] showed that the formation of oxidants is planetwide on Mars. Atmospheric radiative transfer calculations by Kuhn and Atreya[12] found that all latitudes on Mars receive lethal annual dosage of solar UV radiation. Sand dunes are common on Mars[9]. Therefore, all conditions required for photocatalytic oxidation of organics seem to be satisfied, and we conclude that there is no basis for optimism for finding organic molecules anywhere on Mars. Organics could be buried undergound, but the fact that Viking found none under a rock does not support this conjecture.

In addition to the above comparative analysis we can use spectral remote sensing data of Mars to extend the Viking findings. UV and IR spectroscopy are very sensitive techniques in quantitative organic analysis. Therefore, UV and IR reflectance spectra of Mars, when properly interpreted with the aid of laboratory 'ground truth' measurements, can yield the surface chemical composition of areas not examined *in situ*.

Most molecules have spectral signatures in the small range of UV wavelengths 120–320 nm. Unfortunately UV observations of the martian surface are usually hampered by Rayleigh scattering (at $\lambda \leqslant 320$ nm) and absorption (at $\lambda \leqslant 180$ nm) due to carbon dioxide molecules in the martian atmosphere[10,13]. However, during dust storms surface material is raised and suspended as dust in the atmosphere. The 1971 global dust storm was particularly favourable for remotely sensing the physical properties of Mars dust particles, and the UV spectrometer on the Mars-orbiting Mariner 9 spacecraft observed the dust clouds as resolutions and phase angles not possible from the Earth. By modelling the observed phase function (intensity as a function of the scattering angle) of the dust particles with theoretical scattering calculations their complex refractive index ($n - ik$) can be determined. The wavelength dependence of the absorption index k of martian dust is shown in Fig. 1. The absorption increases with decreasing wavelength down to ~210 nm, but decreases at still shorter wavelengths. A structural shoulder in the absorption spectrum occurs near 250 nm. A third feature is also present at ~300 nm. Both the absolute value of k and its variation in the UV are consistent with k values in the visible/IR, determined by Viking Lander spectrophotometric observations of martian aerosols[14]. UV observations of the dust-shrouded Mars by the Orbiting Astronomical Observatory (OAO 2) are also consistent with the Mariner 9 measurements[15].

Abadi and Wickramasinghe[16] have suggested that the absorption feature at 210 nm may be a signature of highly complex organic or pre-biotic molecules in martian dust clouds. Their conclusion is based on similarities between the 210 nm martian dust band and bands in the absorption curves of organic materials, including an extract of the Murchison meteorite[17,18]. Although there is a superficial resemblance between the martian dust absorption spectrum and the data in refs 17 and 18, comparisons reveal important differences in both band strength and position. Searching through more than 2,000 UV absorption spectra of organic compounds[19] we could not find any that closely resemble the dotted curve in Fig. 1. A combination of organic compounds or a sample that we did not examine may have had the required spectral characteristics. However, the following inorganic interpretation is more reasonable because of its simplicity, and because it accounts for all the UV features observed in martian dust.

The suggestion that the UV absorption bands in martian dust are due to electronic transitions in titanium dioxide[13] has been experimentally verified at the Beijing Glass Institute. Titanium oxide was vacuum evaporated onto a fused quartz substrate, and then oxidized by heat treatment[20]. X-ray diffraction study revealed the crystalline structure of the TiO_2 to be in the anatase form. The optical density of the sample was measured with a spectrophotometer at a resolution of $\Delta\lambda/\lambda = 0.001$. The solid curve in Fig. 1 shows the relative absorptivity of the anatase sample, normalized to the peak of martian dust absorption. Molecular orbital calculations predict absorption bands at 220, 250, 258, and 296 nm due to metal–ligand transitions in TiO_2 (tick marks in Fig. 1)[21]. We should also consider whether other electronic transitions (Fe^{2+}, Fe^{3+}) that have been suggested to explain the visible/near IR absoprtion features of Mars[22] may also account for the UV absorption features. Absorption spectra of Fe_3O_4 and $2Fe_2O_3 \cdot 3H_2O$ are also shown in Fig. 1. The ferric and ferrous transitions do not fit the Mars dust data as well as TiO_2. In any case, TiO_2 is expected to dominate the UV spectrum of Mars surface material despite its lower abundance, because its band strength is far stronger than that of the iron oxides below about 320 nm (refs 23–25). Our conclusion is

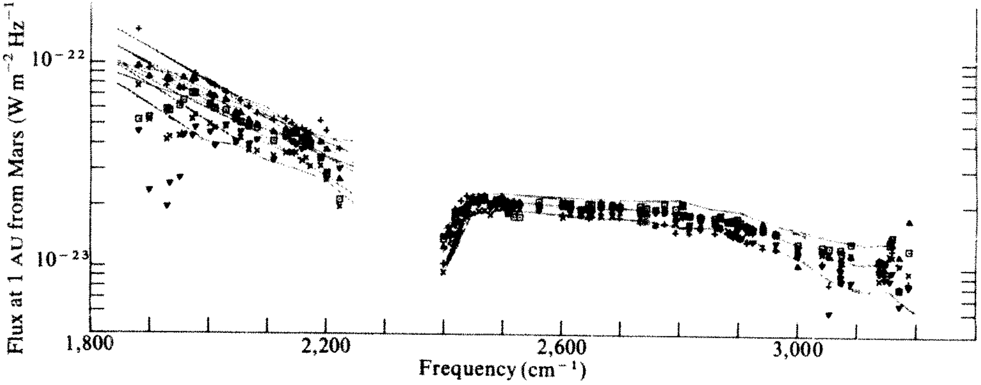

Fig. 2 Observed IR flux of Mars compared with inverse wavelength. Different symbols refer to different observing runs. Different curves were generated by a temperature–albedo model. Reproduced from refs 27, 28, with permission of Reidel, Boston.

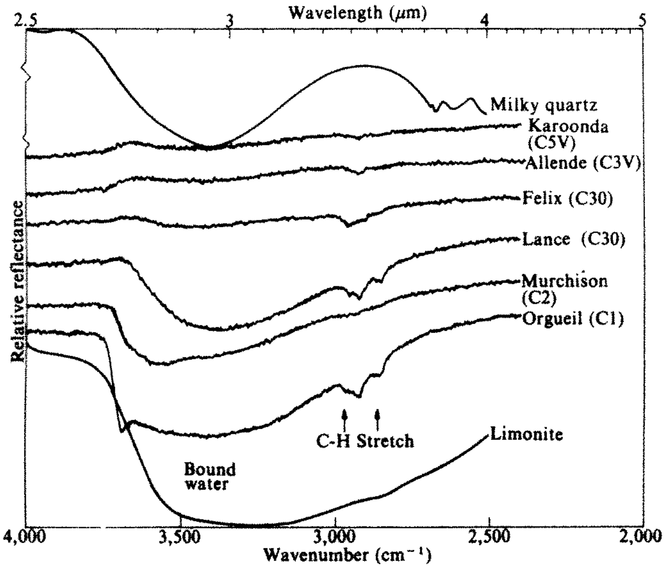

Fig. 3 Relative reflectance of powders (particle sizes between 0 and 74 μm) of quartz, limonite, and carbonaceous chondrites. Petrographical classification in parentheses. Reflectance (relative to MgO) at λ 2.5 μm are: Murchison 7%, Orgueil 9%, Allende 11%, Karoonda 14%, Felix 15%, Lance 17%, limonite 34%, and quartz 82% (see ref. 46). Reflectance measurements of carbonaceous chondrites made by Salisbury are published in part in ref. 39. Quartz and limonite spectra are given in ref. 40.

consistent with the detection of titanium by Viking Lander inorganic analysis[26].

In addition to the UV analysis we may reinterpret IR reflectance spectra of Mars to derive useful upper limits on the organic carbon content of martian soil. Extensive IR spectroscopic studies of Mars have been carried out with sophisticated groundbased, airborne, and spacecraft instrumentation. The martian IR spectrum shows the signatures of atmospheric carbon dioxide, carbon monoxide, water vapour, and oxygen; and of silicates, solid CO_2, bound and frozen water on the surface[22,27–32]. Stringent upper limits have been placed on undetected atmospheric constituents, for example, parts per 10^8 for methane[33–36]. The wavelength interval 3.3–3.6 μm has been especially well scrutinized because nearly all organic compounds containing C and H have absorption bands here due to excitation of the C–H stretching vibration[37,38]. As all gases known to be present in the martian atmosphere[6] are transparent in this spectral region, any absorption feature found superimposed on the wing of the 3-μm water of hydration band may be assigned to organic constituents in Mars surface material. Despite intensive search the C–H absorption bands have never been found on Mars. Figure 2 shows high resolution spectra of Mars taken by Beer[27]. Absorption features due atmospheric CO_2 and water bound in surface material (3,300 cm^{-1} or 3 μm) are clear. However, the C–H bands (2,800–3,000 cm^{-1} or 3.3–3.6 μm) are absent. Observed flux variations in this spectral interval can be adequately accounted for by a simple temperature–albedo model.

Laboratory measurements are useful for quantitative reinterpretations of IR reflectance spectra of Mars. Figure 3 shows laboratory reflectance spectra of quartz, limonite, and representative carbonaceous meteorites[39,40]. The methyl and methylene (symmetric and anti-symmetric) vibration bands are clearly resolved as a doublet on the long wavelength wing of the water of hydration band in the spectra of the carbonaceous chondrites. The strength of the C–H bands correlates with the organic carbon content of the meteorite, for example, Orgueil, 2.5%; Lance and Felix 0.4%; and Allende, 0.2%. The C–H bands are detectable in even in Karoonda, with an organic carbon content of only 0.08%. The 3.3–3.6 μm features are not present in quartz and limonite, representing terrestrial minerals and rocks with organic carbon contents of 0.02–0.06% (ref. 41, 42). Organic carbon content has been estimated to be about 80% of total carbon content by Nagy. The remaining 20% carbon is in carbonates which do not have the C–H bond. Total organic carbon contents of terrestrial rocks are estimated from vaporization-pyrolysis measurements of representative rocks, scaled to that of the Allende meteorite[43]. We conclude that the absence of the fundamental C–H stretching absorption features in the martian reflectance spectra indicates that the organic carbon content of its average surface material is at or below parts per 10^4. The upper limit for organic carbon content pertains to a value averaged over the whole martian planet, as when Mars is observed by low spatial resolution Earth-based IR spectroscopy, or to a value averaged over the field of view (FOV) of spacecraft IR spectrometers, which have best resolution of the order of 100 km. The organic carbon content of an area smaller than the resolution limit might exceed that averaged over the FOV, although Viking GC-MS results make this proposition seem unlikely. Field observations in the dry valleys of Antarctica have shown that soil samples with organic carbon contents <0.1% are generally sterile[44,45]. This implies that Mars in general and areas examined by IR spectroscopy in particular have soil deficient in organic matter, and are unfavourable habitats for life forms based on carbon chemistry.

An inorganic interpretation of Mars' UV reflectance spectrum is, therefore, more plausible than an organic interpretation. The IR reflectance spectrum places a stringent upper limit on the organic carbon content of average martian soil, virtually ruling out biological activities. Laboratory simulation and site comparisons give no reason to believe that organic molecules are preferentially preserved anywhere on Mars. Taken together, the evidence suggests that the sterility of the Viking landing sites is representative of the entire planet.

We thank Drs William H. Pickering and Ta-Jin Kuo for initiating this collaborative effort, and Drs Jack W. Salisbury, Eddie N. Wells, Larry A. Lebofsky, and James L. Gooding for helpful comments. K.D.P. performed part of the research during his tenure as a National Academy of Sciences Senior Resident Research Associate. S.F.S.C.'s participation was made possible through funding from the 1977 Newcomb Cleveland Award, given by the American Association for the Advancement of Science. This research was performed in the People's Republic of China and at JPL. The work carried out at JPL, California Institute of Technology, was sponsored by NASA. The Murchison meteorite specimen used in our research was provided by the Smithsonian Institution.

Chorus-related electrostatic bursts in the Earth's outer magnetosphere

L. A. Reinleitner, D. A. Gurnett & D. L. Gallagher

Department of Physics and Astronomy, University of Iowa,
Iowa City, Iowa 52242, USA

We report here recent studies of wideband plasma wave data from the ISEE 1 and ISEE 2 spacecraft which reveal that whistler-mode chorus emissions in the Earth's outer magnetosphere are often accompanied by high-frequency bursts of electrostatic noise. The chorus features that correlate to the electrostatic bursts have a hook-like frequency–time variation in the frequency range 200–400 Hz, and the associated electrostatic bursts have a frequency range of ~4–8 kHz. In some cases these electrostatic bursts have a harmonic frequency structure with a frequency spacing corresponding to the chorus frequency. This harmonic structure apparently results from the fact that the burst intensity is modulated at the chorus frequency.

Selected wideband spectrograms[1] obtained from ISEE 1 of the chorus-related electrostatic bursts are shown in Figs 1–3. Figure 1 indicates some of the general features of the bursts. In this case, the bursts appear to be strongly correlated to discrete hook-like features in the chorus band[2]. In addition to this example, many cases of the electrostatic bursts are observed in conjunction with intense chorus bands without hooks. In such cases the electrostatic bursts are usually merged together in a nearly continuous band similar to the extended burst in Fig. 1 from about 1738:40 to 1738:50 UT. A comprehensive survey of the locations where the bursts (with or without hooks) are observed has not yet been performed. However, all cases observed have been in the outer magnetosphere near the dayside magnetopause boundary from 7.0 to 17.5 magnetic local time (MLT), about 9–12 R_E and within ~30° of the magnetic equator.

The frequent occurrences of the electrostatic bursts, whether accompanied by hooks in the chorus band or not, as well as the rather limited physical region of occurrence, strongly indicate that the bursts are not caused by instrumental effects. To check that the bursts are not due to some cross-modulation effect in the instrument electronics, wideband data from the IMP 6 spacecraft have been examined. (The plasma wave instrumentation on IMP 6 is detailed in refs 3 and 4.) Although IMP 6 was not in the correct wideband mode to observe both frequencies of interest as often as ISEE 1, intense chorus accompanied by electrostatic bursts have, nevertheless, been found in several passes through the outer magnetosphere on the dayside region.

The electrostatic bursts have several characteristics. The bursts typically occur in a frequency band extending from near the electron plasma frequency f_p as determined by the lower edge of the continuum radiation[4], down to approximately half f_p, as in Fig. 1. In the examples shown, the frequency range of the burst does not extend up into the continuum radiation, although bursts extending up into the plasma frequency have been found. In all cases, the bursts occur at frequencies above the electron gyrofrequency ($f_g \sim 1.2$ kHz in Fig. 1).

The bursts have been described as electrostatic because no wave magnetic field can be detected in association with them. Typically the broadband electric field strength of the bursts are about 50 μV m^{-1}. Because the wave magnetic field remains at the instrument noise level in all cases, a limit can be placed on the electric-to- magnetic field ratio of about $E/cB \geqslant 0.25$ (which corresponds to an index of refraction $n \leqslant 4$). Because no electromagnetic plasma wave mode is known to exist with $E/cB \geqslant 0.25$ in the frequency range $f_g < f_{burst} < f_p$, the bursts are almost certainly electrostatic. The typical field strengths of the chorus emissions associated with the electrostatic bursts are about 300 μV m^{-1} and 40×10^{-12} T.

The electrostatic bursts occasionally have narrowband harmonic structure of the type shown in Fig. 2. The harmonic structure should not be confused with the vertical striations due to the rapid time dependence of the bursts. The harmonic structure is only evident when the chorus emission has a narrow bandwidth, such as when the hook-shaped features occur. The frequency spacing of the harmonic structure corresponds exactly with the instantaneous emission frequency of the chorus burst.

When chorus hooks are found to be correlated with the electrostatic bursts, the onset of the electrostatic burst usually coincides with the minimum frequency of the hook. This relationship can be seen most clearly in the first and last hook in the upper panels of Fig. 3. Note that the electrostatic burst usually continues for a time after the hook has disappeared or merged back into the chorus band.

Comparative studies using both ISEE 1 and ISEE 2, were possible because both spacecraft were in nearly identical orbits with a separation of only hundreds of kilometres. Although virtually identical chorus hooks were found in the electric field wideband data, the electrostatic bursts, while correlated, were not identical at the two spacecraft which indicates that the structure of the electrostatic bursts varies significantly on spatial scales of only hundreds of kilometres. To estimate the wavelength of the electrostatic noise, the electric field strength has been compared on ISEE 1 and 2, which have electric antenna lengths of 215 m and 30 m tip-to-tip. For bursts which had similar characteristics at the two spacecraft, the electric field

The slight interference from 1738:45 to 1739:17 UT (also in Fig. 3) is from the ISEE electron density experiment. $R = 11.04 R_E$; magnetic lat. = 21.1°; MLT = 11.6 h.

0028–0836/82/010046—03$01.00

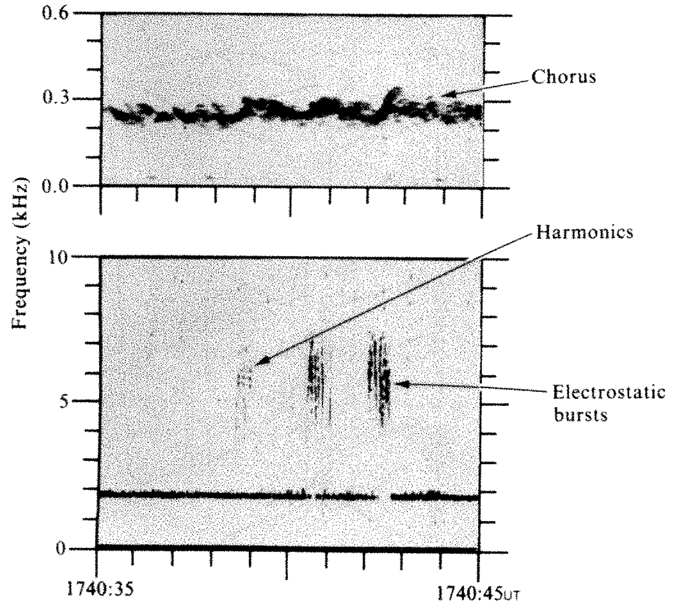

Fig. 2 Wideband plasma wave data showing narrowband harmonic structure for 5 November 1977. $R = 11.01\ R_E$; magnetic lat. = 21.1°; MLT = 11.7 h.

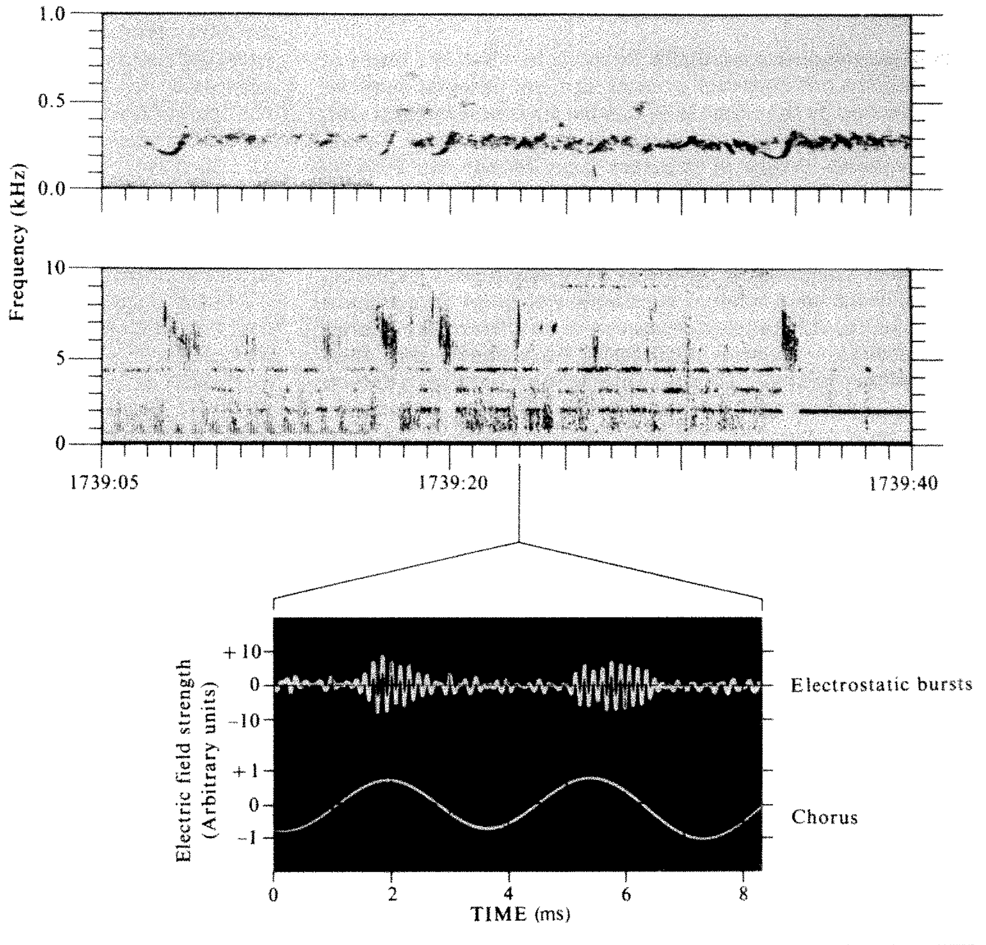
strengths were in good agreement, thereby indicating that the wavelength of the bursts must be longer than both of the antennas, implying a wavelength for the electrostatic bursts of $\lambda_{\text{burst}} > 215$ m.

Comparisons of the waveforms of the chorus and the electrostatic bursts reveal several interesting features. The lower panel of Fig. 3 shows the electric field versus time for both the chorus and the electrostatic burst. The lower signal is that of the chorus while the upper high frequency signal is the associated electrostatic burst. Both signals have been run through bandpass filters to eliminate signals not in the frequency band of interest. Note that the time duration of these waveform data is only 8 ms. The waveform therefore comprises only a small portion of the electrostatic burst from which it was taken. As can be seen, the electrostatic noise is actually composed of many shorter bursts of a high frequency signal which is modulated at the chorus frequency. Thus, the harmonics evident in Fig. 2 are a modulation effect caused by the periodic pulsing of the electrostatic noise at the frequency of the chorus emission. In the cases where the harmonics do not occur, the chorus does not occur as a single frequency but rather as a band of frequencies, which tends to blend harmonics into a broad continuous spectrum.

The correlation between the envelope of the bursts and the chorus waveform is often not as good as the example shown; however, the basic modulation effect in which the intensity of the high frequency emission maximizes at a given phase of the chorus waveform is usually evident. Also, despite the apparently abrupt initial turn-on of the bursts in the usual wideband data, waveform data show a gradual increase in the amplitude of the high frequency bursts, as well as a gradual decrease toward the end of each burst. For the case shown in the lower panel of Fig. 3, the frequency of the electrostatic emission is 6.7 kHz (±0.5 kHz) which is near but below the plasma frequency of 8.5 kHz (±0.5 kHz) as determined by the lower cutoff of the continuum radiation.

The strong correlation between the envelope of the electrostatic bursts and the chorus waveform suggests some strong physical interaction between these two wave modes. We currently believe that the chorus is phase bunching electrons at the phase velocity of the whistler mode and that these resonant electrons are triggering an electrostatic instability through a two-stream (or bump-on-tail) type mechanism[5]. We are not certain of the exact identification of the electrostatic mode involved but the best candiate seems to be a Langmuir wave or related beam mode, because the emission occurs very close to the local electron plasma frequency. The shift in the frequency of the electrostatic emission below the plasma frequency could

Fig. 3 The lower panel shows the oscilloscope waveform pattern taken from the very short burst indicated in the upper panels of wideband data for 5 November 1977. The low frequency signal in the bottom of the lower panel is the chorus waveform, while the high frequency signal bursts at the top of the lower panel are the electrostatic bursts. The phase of the chorus waveform may differ from that shown by a constant (instrumental) phase factor. $R = 11.04\ R_E$; magnetic lat. = 21.1°; MLT = 11.6 h.



be due to either a Doppler shift or an intrinsic effect related to the two-stream interaction.

We also believe that the correlated whistler and electron plasma oscillation bursts detected in the solar wind by Kennel *et al.*,[6] are probably essentially identical to the chorus related electrostatic bursts described here. Most differences are attributable to differing plasma parameters in the two different regions of interest. The hypothesized interaction between these two wave modes is seen as a better alternative than the secondary impulsive electron heating mechanism proposed by Kennel *et al.*[6].

We thank Dr Alain Roux for valuable suggestions on theory, and Dr Roger R. Anderson for help with analysis of the data. This research was supported by NASA through grant NGL-16-001-043 from NASA Headquarters and contract NAS5-20093 with Goddard Space Flight Center, and the Office of Naval Research.

Coordination model for the defect structure of hyperstoichiometric UO$_{2+x}$ and U$_4$O$_9$

G. C. Allen, P. A. Tempest & J. W. Tyler

Central Electricity Generating Board, Berkeley Nuclear Laboratories, Berkeley, Gloucestershire GL13 9PB, UK

Non-stoichiometric compounds or solids in which the ratios of the amounts of elements present are not integral may be characterized by the formula MX$_x$ where x is non-integral and, in many crystalline compounds, may vary over quite a wide range without change of structure type. Ideally the thermodynamic stability and physical properties of such compounds should be related to the same atomic and electronic model but the ways in which various simple structures adapt to departures from ideal composition have not been adequately explored. Models based on a random distribution of point defects have proved successful but selected area electron diffraction and ultra high resolution electron microscopy have shown that their distribution is not simple. Interaction between defects produces microscopic sub-structures or clusters introducing specific local properties. Although our knowledge of the principal morphological features of sub-structures has advanced, their precise interatomic arrangements are generally unknown. Here we derive a model for non-stoichiometric oxides of uranium.

Some oxides of the lanthanide or actinide elements have fluorite-type structures and a propensity towards deviation from simple stoichiometry. Oxygen can be transferred easily between the MO$_x$ lattice and the ambient gas phase. UO$_2$ is no exception and its stoichiometric form is not easy to obtain. Although some oxidation occurs even at very low temperatures, homogeneous oxidation products are not formed in this way. At room temperature, surface oxidation processes are responsible for the non-stoichiometric nature of UO$_2$ in dry air and further oxidation is controlled by diffusion of oxygen either in the dioxide lattice or through a diphasic surface layer. Only above ~300 °C does the oxidation become so rapid that uniform accessibility of oxygen to the entire sample becomes a factor. In many defect oxides with the fluorite structure non-stoichiometry occurs through untenanted anion sites, the cation sublattice remaining essentially intact. The formation of UO$_{2+x}$ and U$_4$O$_9$, however, occurs by the incorporation of additional oxygen atoms at interstitial sites in the fluorite structure of UO$_2$ rather than the creation of uranium vacancies, and the occupation number of cations again remains the same as in the stoichiometric compound.

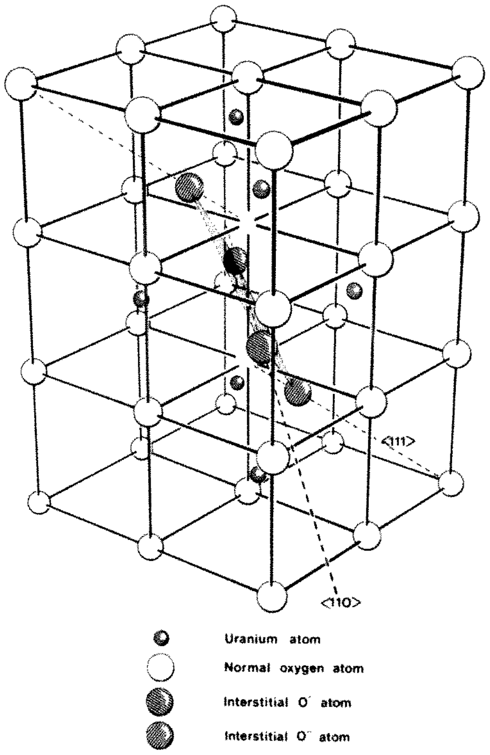

Fig. 1 The oxygen sublattice showing a 2 : 2 : 2 cluster.

The interstitial sites have been identified by Willis[1,2]. These are of two types which are displaced from the cubic-coordinated sites by about 1 Å in the ⟨110⟩ and ⟨111⟩ directions. This aggregate or 'cluster' depicted in Fig. 1 has the 2 : 2 : 2 configuration which contains two oxygen interstitial atoms along ⟨110⟩ identified as 0′, two oxygen interstitial atoms along ⟨111⟩ identified as 0″, and two vacancies in the oxygen sublattice. The formation of these clusters contrasts with the structural defects present in other anion-excess fluorite-related superlattices in which the basic oxygen cube of the fluorite structure changes to a square antiprism[3].

Martin[4] suggested that ordering of defects in fluorite lattices could occur to form chains of coordination defects. For MO$_{2-x}$ phases Martin's recognition of this phenomenon was based on assemblies of vacancy point defects. However, a detailed analysis of the X-ray photoelectron spectrum of UO$_{2+x}$ suggested a defect grouping based on a unique coordination of Willis type clusters in which an individual oxygen atom has a total negative charge less than in the isolated oxygen ion[5]. Thus ordering similar to that suggested by Martin could occur in UO$_{2+x}$ based on oxygen interstitials. Our model for the structure of UO$_{2+x}$ including U$_4$O$_9$, incorporates a chain-like coordination of oxygen defect clusters.

In Fig. 1 the 2 : 2 : 2 cluster bridges two uranium atoms which then become 9-fold rather than 8-fold coordinate. Using neutron diffraction data[6] for this UO$_9$ coordination polyhedron the internuclear separations are; 6(U–O) at 2.37 Å, 2(U–O′) at 2.22 Å, and 1(U–O″) at 2.29 Å emphasizing the higher degree of covalency in the uranium-cluster bonds. These calculations require that the U–U distance be fixed although in practice, this is unlikely. Single crystal X-ray diffraction studies of defect fluorite-type structures reveal consistent lengthening of U–U and shortening of O–O distances around a vacant oxygen site[7] and similar polarization effects would be expected in the vicinity of a cluster. This would shorten the U–U interatomic distance

0028–0836/82/010048—02$01.00

across the cluster and create preferred interstitial oxygen sites along the opposite edge of the oxygen cube containing the original defect grouping. Thus in addition to the tendency for clusters to order under coulombic forces to develop a superstructure, on geometrical grounds we can postulate the formation of a 2:2:2 cluster chain along $\langle 110\rangle$. A $\langle 110\rangle$ chain in the oxygen sublattice is shown in Fig. 2 and its relationship to the conventional UO_2 unit cell is given in Fig. 3.

Within the chain each uranium atom now has the coordination number 10. Most models for the anion excess phase invoke doubly charged intersitials (O_i^{2-}) compensated by singly charged holes (h^+) present as U^{5+} cations[2]. At first sight bond length data seem to support this view. The average U–O separation in most metal uranate (VI) structures is 2.07–2.10 Å but in the eight coordinate $CaUO_4$ structure this distance is 2.21 Å (ref. 8) which approaches the values derived above. Data from measurements of the X-ray photoelectron spectra in the U4f region may also be interpreted in terms of a uranium atom in crystallographically inequivalent sites where it apparently resides in 4+ and 6+ ionic configurations[9,10] so that although ESR measurements on uranates favour the presence of U^{5+} in U^{6+} lattices[11] this may not be the case in the fluorite structure of UO_2.

The length and frequency of chains determines the overall nature of the structure. For low values of x in UO_{2+x} a random distribution of clusters is envisaged. As x increases the probability of oxygen interstitials being influenced by clusters already formed increases. Gradually as x approaches 0.25 cluster chains develop and become ordered. Continuous chains are only allowed in every alternate uranium sublattice layer parallel to $\langle 001\rangle$ because of O″ interference in the oxygen sublattice. At a distance of closest approach of $2\sqrt{2}a_0$ (where a_0 is the lattice parameter of the parent UO_2 fluorite lattice) in the $\langle 110\rangle$ direction only 32 clusters can be accommodated by a unit cell of edge $4a_0$ which yields the composition of U_4O_9 exactly, and is consistent with the superlattice observed by Willis[6]. A chain spacing of $\frac{3}{2}\sqrt{2}a_0$ parallel to $\langle 110\rangle$ yields U_3O_7 but is not consistent with the U_4O_9 superlattice. Any increase in oxygen content above $UO_{2.33}$ would involve severe distortion of the parent fluorite lattice as additional oxygen atoms would have to be accommodated by oxgyen cubes already distorted by O′ or O″ interstitials. Not surprisingly the next characterized oxide phase U_3O_8 has a completely different structure. The increased electrostatic force between uranium atoms separated by a 2:2:2 cluster produces a lattice shrinkage along the unique [110] chain axis. Conversely O′ interstitials along $[1\bar{1}0]$ produce a lattice expansion. Hence in U_4O_9 the presence of one or several preferentially oriented chains will distort the superlattice from cubic symmetry. Indeed distortion from the cubic to rhombohedral structure in the superlattice of U_4O_9 has been observed[12].

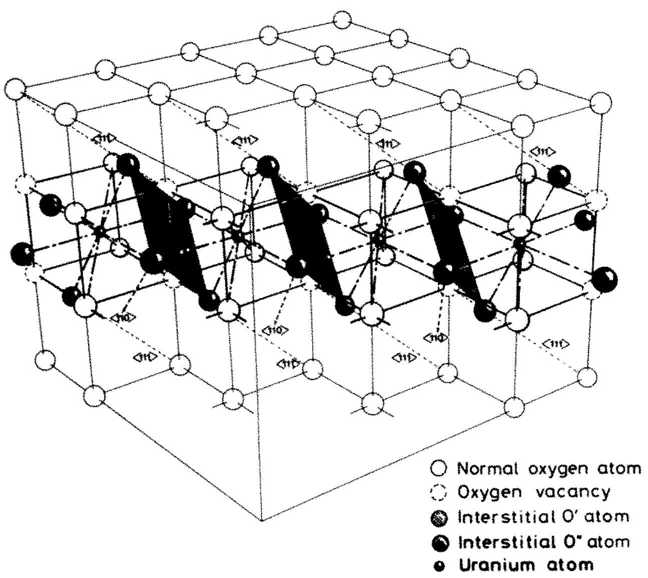

Fig. 2 A chain of 2:2:2 clusters in the oxygen sublattice.

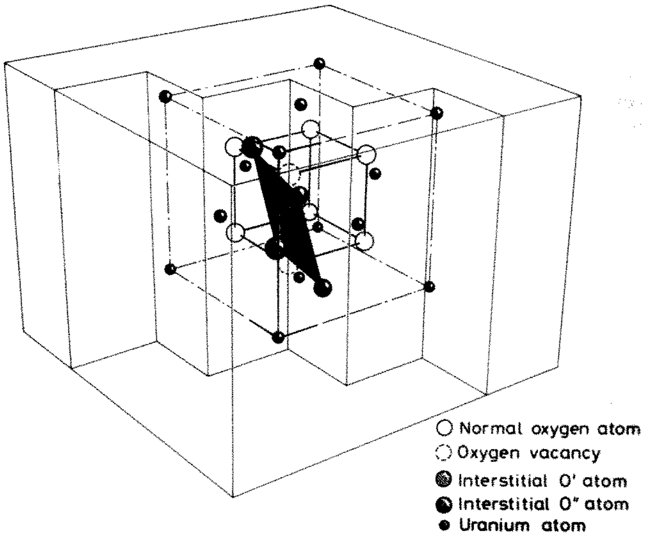

Fig. 3 The relationship between a 2:2:2 cluster and the normal fluorite unit cell.

Although the U_3O_7 composition could be accommodated by the above model no complete experimental determination of its crystal structure exists. Lattice dimensions have been reported in terms of a face-centred tetragonal cell derived from the UO_2 structure but the tetragonal phase may be metastable.

Austenitic stainless steels have become important high-temperature structural and containment alloys in applications ranging from industrial processes to energy generation and conversion. The AISI Type-300 series of iron–base austenitic stainless steels, in particular, is widely used as a barrier or primary containment material for both nuclear and fossil fuels operation at temperatures as high as 700 and 1,000 °C, respectively. Thus any observed deleterious effect of chemical environment on the alloy mechanical properties such as the 'hot' embrittlement of austenitic stainless steel by liquid zinc[1,2] is very

0028-0836/82/010049—03$01.00

important and, indeed, Old[3] has mentioned that fission products such as caesium, cadmium and tellurium might embrittle the austenitic stainless steel cladding of fast reactor fuel pins in certain conditions. The few investigations of the high temperature mechanical behaviour of iron–base austenitic stainless steels in chemical environments intended to simulate in-reactor conditions have not positively identified any particularly severe chemomechanical degradation, such as that accompanying stress corrosion cracking or liquid metal embrittlement. We now report the observation of rapid, severe embrittlement of AISI 316 stainless steel by liquid tellurium–caesium mixtures in the temperature region 500–700 °C. Our results were obtained using a test technique that involves radially deforming small ring specimens contained inside an environmental chamber by compressive loading at a uniform displacement rate. This ring compression test technique has the advantages of facile control of the chemical environment and ease of adaptation for work with irradiated materials.

AISI 316 is an austenitic iron–base alloy containing by weight about 17% Cr, 13% Ni, 2.5% Mo, 2% Mn, 0.5% Si, 0.06% C and various trace elements. The liquid Te–Cs mixtures, which were applied to the alloy specimens as thin coherent coatings, contained dissolved oxygen at very low activity levels. The ring specimens used in our analyses were short (6.35 mm) lengths of 5.84 mm o.d., 0.381 mm wall AISI 316 seamless tubing with average grain diameters in the range 25–36 μm. Specimens, neutron-irradiated to a fluence of 8×10^{22} neutrons cm^{-2} ($E >$ 0.1 MeV) at 488 °C in the Experimental Breeder Reactor-II at Idaho, were also tested.

Photomicrographs and scanning electron fractographs of unirradiated 20% cold-worked AISI 316 specimens stressed and broken in the presence of equimolar Te–Cs mixtures at 550–625 °C are shown in Figs 1–3. Figure 1 indicates the extreme brittleness of the fracture obtained at 625 °C, as illustrated by the sharp drop in load-bearing capability just past the yield load. The scanning electron micrographs of the 625 °C fracture surface shown in Figs 2*b* and 3*a* indicate the totally intergranular nature of the nonductile fracture. Similar results have been obtained on solution-treated AISI 316 and the fast neutron-irradiated 20% cold-worked materials. The embrittlement appeared to be even more marked in the irradiated material, occurring throughout the temperature range 450–625 °C with a peak load consistently lower than the load corresponding to initial yielding.

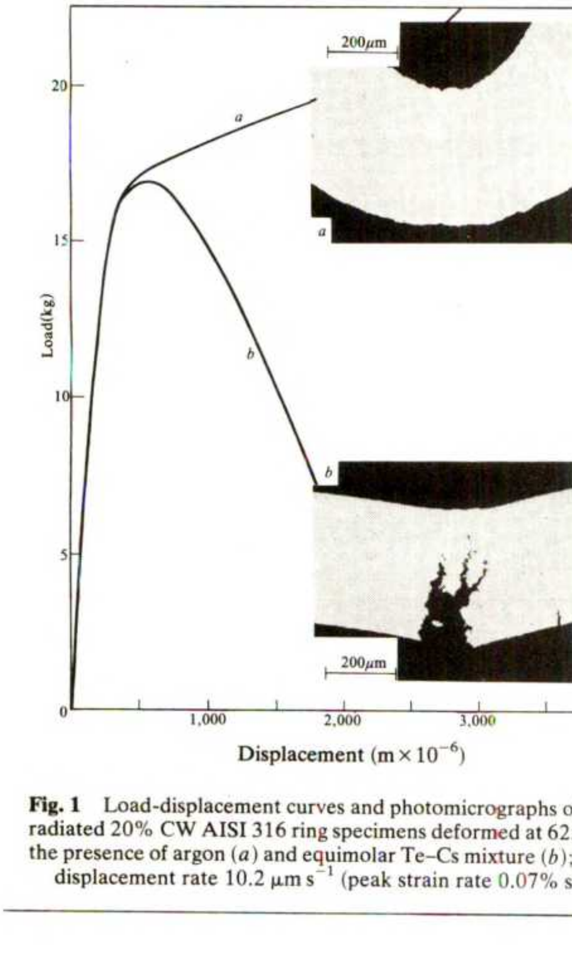

Fig. 1 Load-displacement curves and photomicrographs of unirradiated 20% CW AISI 316 ring specimens deformed at 625 °C in the presence of argon (*a*) and equimolar Te–Cs mixture (*b*); linear displacement rate 10.2 μm s^{-1} (peak strain rate 0.07% s^{-1}).

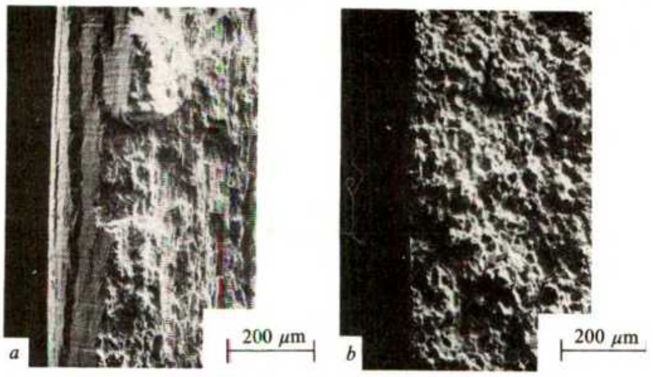

Fig. 2 Low magnification scanning electron fractographs of unirradiated 20% CW AISI 316 specimens stressed and broken in the presence of equimolar Te–Cs at 550 °C (*a*) and 625 °C (*b*); the direction of fracture is left to right for each specimen.

In equivalent test conditions, caesium alone did not embrittle cold-worked AISI 316, neither did simulated fission product mixtures of cadmium, indium, tin, antimony and iodine, with or without (excess) caesium. Liquid tellurium caused some reduction in yield stress at 625 °C, but no observable loss of ductility at either 475 °C or 625 °C. The marked embrittlement caused by liquid Te–Cs mixtures seems to be restricted to compositions lying between Cs_2Te and Te and, due to the absence of any concomitant Cs, Te-assisted oxidation of the alloy specimens, it is assumed to proceed independently of this corrosion process.

The observed 'hot' embrittlement of Type 316 stainless steel by liquid Cs–Te exhibits many features characteristic of 'classical' liquid metal embrittlement[3]. Only small quantities of the embrittling agent are required but it must be liquid and must be in intimate contact with the test specimen during loading. In one test, after initially coating the specimen with the Cs–Te mixture corresponding to the conditions for the test results given in Fig. 1, the coating was removed with successive washes of water and absolute ethanol. The load-deflection pattern for this specimen was found to be identical to the uncoated material, indicating that the embrittlement effect requires the presence of a surface layer of the liquid metal—a typical feature of liquid metal embrittlement. The stressed specimen in all cases exhibits normal elastic deformation up to some critical strain but, once this threshold has been exceeded, nonductile fracture rapidly follows; and, at a given strain rate, embrittlement occurs within a well-defined range of temperature whose lower limit usually coincides with the melting temperature of the embrittling agent.

The unique feature of this particular embrittlement process is the apparent chemical synergism between tellurium and caesium as embrittling agents—a synergism that is manifested by a marked dependence of embrittling agent activity on tellurium chemical potential. On the other hand, the activity of the embrittling agent did not appear to be markedly influenced by oxygen chemical potential, at least within the relatively narrow range of values expected inside a fast breeder reactor oxide fuel pin. The concept of 'inert carriers' in liquid metal embrittlement has been discussed elsewhere[3]; however, in the present case the role of caesium is thought to be more complex, being also possibly related to the manner in which wettability and tellurium activity change as a function of Cs/Te ratio.

We believe that the present results are the first observation of synergistic 'hot' embrittlement of AISI 316 stainless steel by liquid Te–Cs mixtures. This particular chemical synergy parallels the synergy operating in Cs, Te-assisted oxidative corrosion of AISI 316 that sporadically appears inside fast reactor oxide fuel pins[4], however, the mechanisms and consequences seem to be remarkably different.

Our recent results may have important implications for the design and operation of advanced fast reactor fuel pins. The composition and chemical states of fission products deposited on the inside surface of a fast reactor oxide fuel pin cladding are influenced by processes such as transport under thermal gradients, selective chemical reactions between fission products and between fission products and the fuel, and the temperature at a given location. Preliminary thermochemical analyses of the conditions inside operating fast reactor fuel pins indicate that Cs/Te ratios <2 are possible at the fuel-cladding interface. However, for the specific mechanism discussed here to be operative in a particular fuel pin, the loading on the cladding would have to produce the specific threshold strain for liquid metal embrittlement at the same time that the chemical conditions are satisfied. Estimates of the associated probability will have to await the outcome of detailed chemical and mechanical modelling studies.

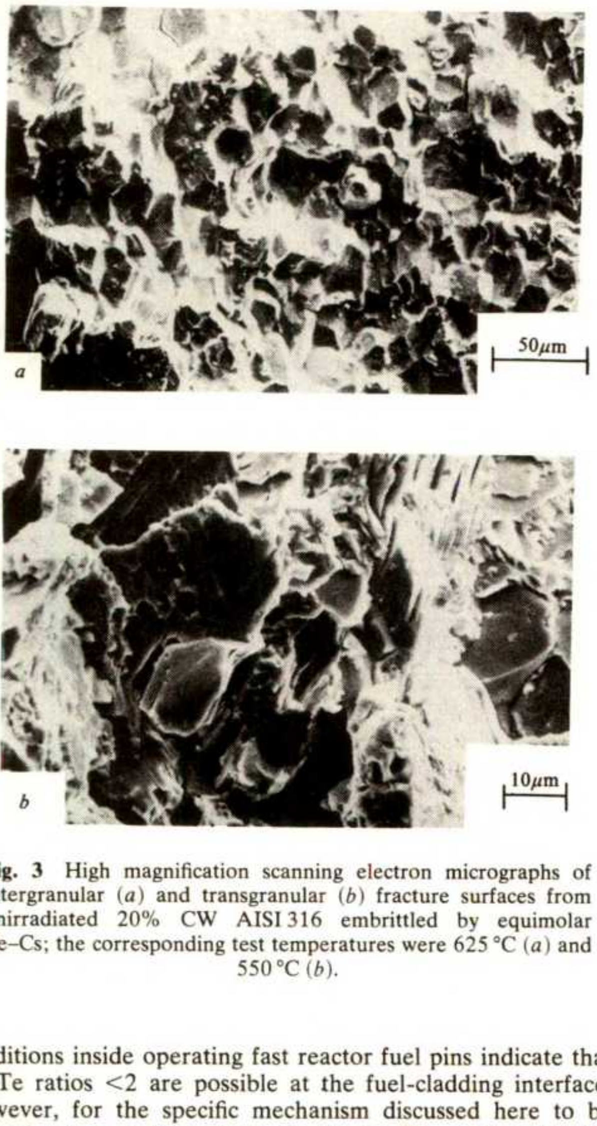

Fig. 3 High magnification scanning electron micrographs of intergranular (*a*) and transgranular (*b*) fracture surfaces from unirradiated 20% CW AISI 316 embrittled by equimolar Te–Cs; the corresponding test temperatures were 625 °C (*a*) and 550 °C (*b*).

We thank T. A. Lauritzen and W. H. Reineking for experimental assistance, the US Department of Energy for financial support, and personnel at the Hanford Engineering Development Laboratory for supplying irradiated stainless steel specimens.

Carotenoid transformations in coastal marine waters

Daniel J. Repeta & Robert B. Gagosian

Department of Chemistry, Woods Hole Oceanographic Institution,
Woods Hole, Massachusetts 02543, USA

Rapidly sinking large particles contribute a major portion of the mass flux from marine surface waters to the sea floor. The recognition that organic matter associated with these particles undergoes major alterations in its chemical composition during vertical transit has raised new questions on the role of rapid transformation processes in carbon and nitrogen cycling, benthic nutrition, and post-depositional degradation[1]. Analysis of specific organic compounds has established some of the compositional changes of these transformations[2–4]. However, most of the changes observed represent the sum of biological production and degradation. For example, bacterial and chemical degradation of fatty acids in the water column may be completely masked by an even greater production of these compounds by zooplankton. Hence it is often difficult to distinguish between competing degradative processes, and to assess the relative significance of each. Carotenoid pigments have characteristics which make them particularly suitable for use as organic tracers to distinguish between short-term degradation processes. Carotenoids are widely distributed in both photosynthetic and nonphotosynthetic organisms; many of them are source specific; they contain diverse functional groups; and they represent one of the more labile biogenic compound classes in the sea. We report here for the first time the isolation and identification of carotenoid transformation products from sediment trap experiments conducted in coastal marine waters, and discuss the source and significance of observed transformation products with respect to a proposed degradation pathway.

Sediment traps were deployed in Buzzards Bay, Massachusetts (41°32′ N, 70°42′ W) for two 30-day periods between 20 May and 23 July 1980. Traps were set 4 m below the surface in a 10-m water column. Collected material was filtered and sonic-extracted with methanol (twice, 20 min each) and dichloromethane (once, 20 min). Extracts were concentrated

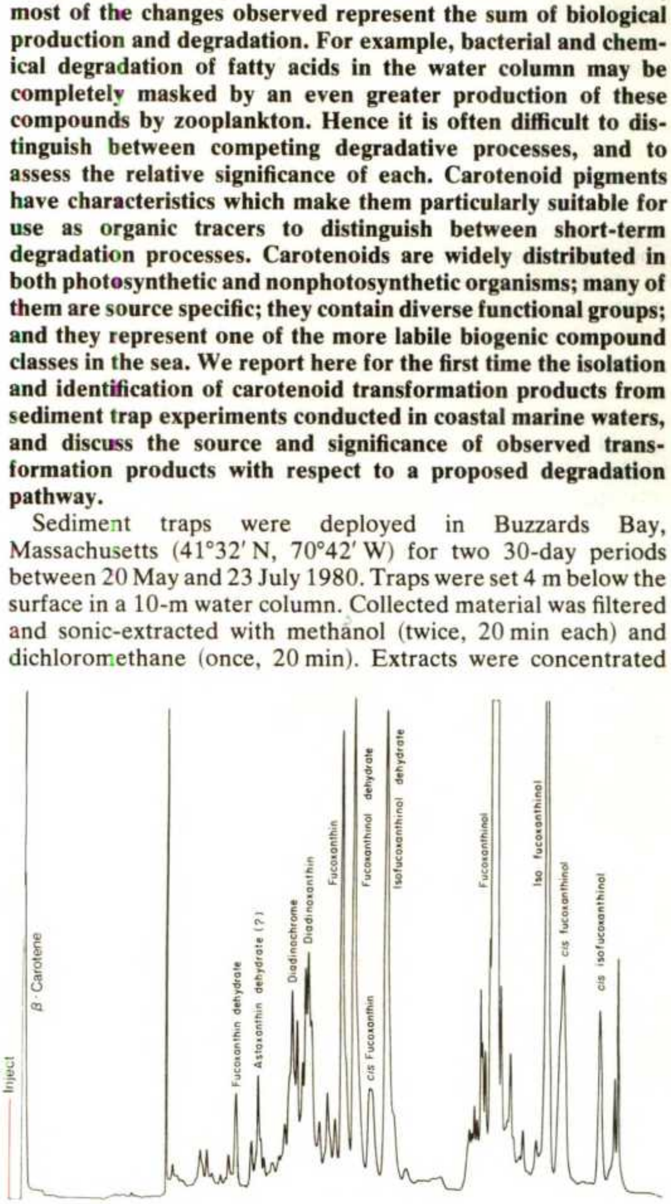

Fig. 1 HPLC trace of Buzzards Bay sediment trap sample no. 3. Conditions are: 30 × 3.9 mm 5 μm amino column, eluted with a linear gradient of 0–13% THF/methanol (80/20, v/v) in hexane at 2 ml min^{-1} for 45 min. After 55 min the eluant was stepped to 30% THF/methanol for an additional 10 min. Detection was at 436 nm.

Table 1 Fucoxanthin metabolites in Buzzards Bay sediment trap 3, 21 June–23 July 1980

	% Total*	% Phytoplankton
Fucoxanthin (Ia)	5	100[7]
Fucoxanthinol (Ib)	69	Trace[8]
Isofucoxanthinol (IIb)	12	ND
Fucoxanthin dehydrate (IIIa)	1	ND
Fucoxanthinol dehydrate (IIIb)	6	ND
Isofucoxanthinol dehydrate (IV)	7	ND
	100%	

ND, not detected.

* Total fucoxanthin-derived pigments, relative abundances not corrected for small differences in extinction coefficients (see ref. 9).

under reduced pressure then separated into compound classes by gel permeation chromatography using 100 Å μStyragel (Waters Associates) with dichloromethane as the mobile phase. This procedure removes low-molecular weight lipids and chlorophyll pigments which interfere with subsequent steps in the analysis. The carotenoid fraction was collected, reconcentrated, then separated into individual components by high pressure liquid chromatography (HPLC) using a Spherisorb 5 μm amino column (300 × 3.9 mm) eluted with a linear gradient of hexane and 0–13% THF/methanol (80/20, v/v) at 2 ml min^{-1} (Fig. 1). Carotenoids were detected spectroscopically at 436 nm, collected, and further analysed by visible spectroscopy and mass spectrometry. Mass spectra were collected on a Finnigan 3200 quadrapole spectrometer interfaced with an INCOS (Finnigan) 2300 data system. Conditions are described in Fig. 2 legend. All operations were performed at or below 20 °C and in low light conditions. A more detailed description of the analytical method will be given elsewhere.

The lability of carotenoids has posed severe problems in their analysis[5]. When discussing geochemical transformations in particular, care must be taken to ensure transformation products are not artefacts of the analytical procedure. Analysis of blanks spiked with carotenoid mixtures (astaxanthin, β-carotene, diadinoxanthin, fucoxanthin and lutein), and of cultured phytoplankton (*Peridinium trichoidium*) of known carotenoid composition[6] showed that no degradation other than *cis* ⇄ *trans* isomerization occurs during our analytical work-up.

Fucoxanthin (Ia) is the major carotenoid in diatoms and a few dinoflagellates, often constituting 70–90% of the total carotenoids[7]. In our sediment trap samples, fucoxanthin comprised only 4% of the total carotenoid and 5% of the total fuco-pigments (Table 1, Fig. 1). The remaining 95% of the total fuco-pigments consisted of the fucoxanthin transformation products fucoxanthinol (Ib), isofucoxanthinol (IIb), fucoxanthinol dehydrate (IIIb), isofucoxanthinol dehydrate (IV) and fucoxanthin dehydrate (IIIa). Together these compounds constitute 82% of the total carotenoids with diadinoxanthin (V) and diadinochrome (VI) contributing another 3% and 1%, respectively. Fucoxanthinol (Ib) has been reported as a minor component of some algae, and is thought to be an intermediate in fucoxanthin biosynthesis[8,9]. Isofucoxanthinol (IIb) is known to arise from base-catalysed epoxide opening and is commonly cited as an analytical artefact[10]. For reasons outlined above, we believe that the opened epoxides (iso-compounds) in these samples are not artefacts of the analytical method, but are due to chemical transformations in the water column. We know of no reports of naturally occurring dehydrates (IIIa, b) of either fucoxanthin or fucoxanthinol.

Fucoxanthinol (Ib) (Fig. 2) is the most abundant pigment in the samples (Table 1). Acylation with acetic anhydride in pyridine yields fucoxanthin acetate which co-elutes with standard fucoxanthin acetate synthesized from fucoxanthin (see Fig. 2 legend, which gives mass spectrometry and IUPAC data for all compounds discussed in this paper). Thermal isomerization of fucoxanthin acetate produces an equilibrium mixture of *cis* isomers identical in both chromatographic retention time (HPLC) and relative abundance to those derived from the standard. The ester hydrolysis which converts fucoxanthin to fucoxanthinol can occur by two pathways, a base-catalysed chemically mediated ester hydrolysis, or biochemical metabolism. Base-catalysed ester hydrolysis seems unlikely as epoxide opening should precede ester hydrolysis[10]. In our samples fucoxanthinol, which still contains the epoxide group, predominates over isofucoxanthinol, its open epoxide counterpart. Biochemical metabolism by zooplankton and other higher organisms seems a more likely source. Fucoxanthinol has been found as a major fuco-pigment in the guts of sea urchins[11], thus it is not unreasonable that other higher organisms have the ability to hydrolyse the ester without rearranging the epoxide. As particles collected in sediment traps are thought to represent material which has been extensively reworked by heterotrophic

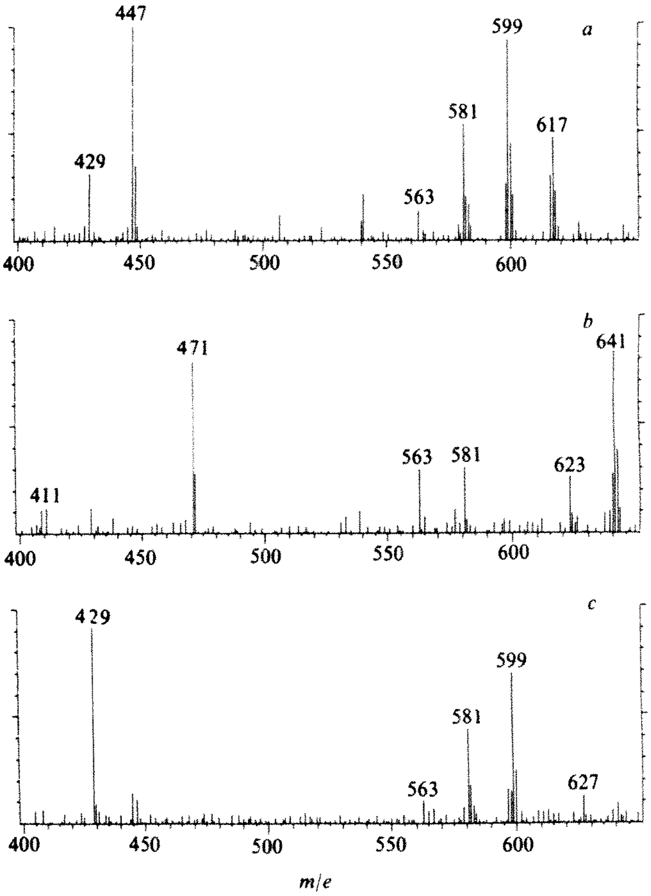

Fig. 2 Chemical ionization mass spectra of *a*, fucoxanthinol (Ib) (M+1 = 617, M+1-18(-H_2O) = 599, M+1-18-18 = 581, M+1-18-18-18 = 563, M+1-170 (cleavage to the 7,8 ketone) = 447, M+1-170-18 = 429); *b*, fucoxanthin dehydrate (IIIa) (M+1 = 641, M+1-18 = 623, M+1-60(-acetate) = 581, M+1-18-60 = 563, M+1-170 = 471); and *c*, fucoxanthinol dehydrate (IIIb) (M+29 = 627, M+1 = 599, M+1-18 = 581m M+1-18-18 = 563, M+1-170 = 429); CH_4 reactant gas 900 μm, ionization voltage 130 eV, ionization current 500 μA. Where: fucoxanthinol (Ib) (5,6-epoxy-3,3′,5′-trihydroxy-6′,7′-didehydro-5,6,7,8,5′,6′-hexahydro-β,β caroten-8-one) (M+1 = 617, M+1-18 = 599, M+1-18-18 = 581, M+1-18-18-18 = 563, M+1-170-18 = 429). Fucoxanthin acetate (5,6-epoxy-3,3′,5′-trihydroxy-6′,7′-didehydro-5,6,7,8,5′,6′-hexahydro-β,β caroten-8-one, 3,3′-diacetate) (M+1 = 701, M+1-18 = 683, M+1-60 = 641, M+1-18-60 = 623). Fucoxanthin dehydrate (IIIa) (5,6-epoxy-3,3′-dihydroxy-4′,6′,7′-tridehydro-5,6,7,8,6′-pentahydro-β,β caroten-8-one 3′-acetate) (M+1 = 641, M+1-18 = 623, M+1-60 = 581, M+1-18-60 = 563, M+1-170 = 471). Fucoxanthinol dehydrate (IIIb) (5,6-epoxy-3,3′-dihydroxy-4′,5′,7′-tridehydro-5,6,7,8,6′-pentahydro-β,β caroten-8-one) (M+1 = 599, M+1-18 = 581, M+1-170 = 429). Dehydro-fucoxanthin diacetate (5,6-epoxy-3,3′-dihydroxy-4′,6′,7′-tridehydro-5,6,7,8,6′-pentahydro-β,β caroten-8-one 3,3′-diacetate) (M+1 = 683, M+1-60 = 623, M+1-212 = 471). Double bond in dehydrates tentatively assigned to the 4′,5′ position. (See ref. 10.)

organisms[1], we propose that fucoxanthinol represents a metabolite of heterotrophic activity. Other studies conducted in our laboratory, concerned with the direct collection of zooplankton faecal pellets from field cultures, verify this hypothesis[12].

The mass spectra of fucoxanthin dehydrate (IIIa) and fucoxanthinol dehydrate (IIIb) (Fig. 2) are both consistent with loss of the tertiary alcohol at the 5′ position (Fig. 3). The mass fragment M + 1-170 arises from a cleavage of the 7,8 bond α to the 8-ketone. The resulting mass fragments (471, 429 AMU) correspond to a loss of a hydroxyl group at either the secondary 3′ or tertiary 5′ position. Acylation of the isolated fucoxanthinol dehydrate (IIIb) yields a diacetate. Acetic anhydride in pyridine acylates only primary and secondary alcohols in the conditions used in our synthesis. The mass increase of 84 AMU for the acylated dehydrate over the underivatized parent is consistent with the esterification of the two hydroxyl groups at the 3 and 3′ position. Therefore, dehydration proceeds with the loss of the 5′ alcohol. Sufficient amounts of fucoxanthin dehydrate (IIIa) could not be isolated to derivatize, hence our conclusion of 5′ hydroxyl loss for this compound rests on mass spectral evidence alone.

Determining the mechanism of dehydration is difficult. There is little evidence in favour of either a biochemically or chemically mediated reaction. Chemically, an acid-catalysed dehydration reaction seems most likely. However, we find substantial amounts of the unrearranged 5,6 epoxide, diadinoxanthin (V) in our samples. In acidic conditions the 5,6 epoxide rapidly rearranges to the 5,8 furanoxide, diadinochrome (VI)[13]. If the acidic conditions necessary to dehydrate fucoxanthin existed in our samples, all the diadinoxanthin should have rearranged to the 5,8 furanoxide. Although some diadinochrome was observed, we believe that dehydration is probably not a result of chemical acid catalysis, but a more site-specific metabolic reaction.

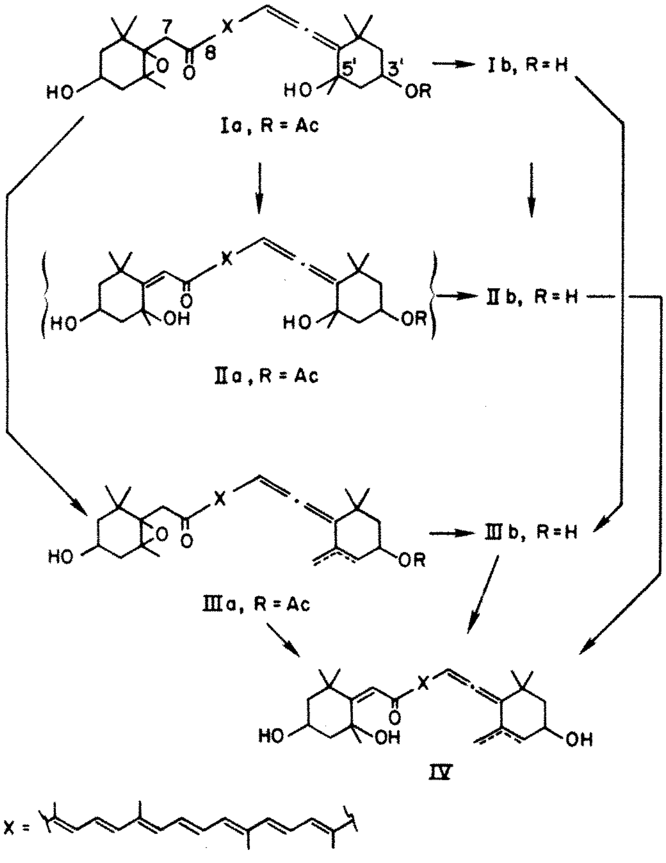

Fig. 3 Proposed pathway showing ester hydrolysis, dehydration and epoxide opening for biochemical and chemical degradation of fucoxanthin. Compound in parentheses was not isolated in this study.

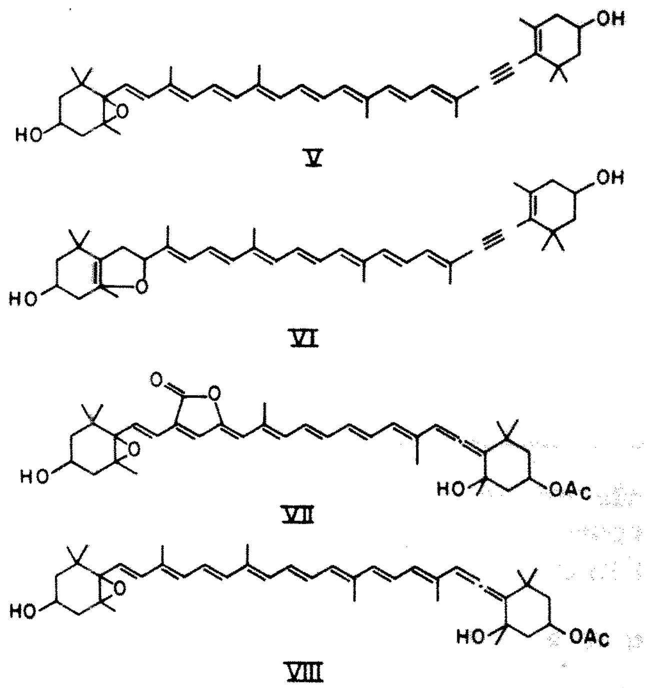

Fig. 4 Molecular structure of diadinoxanthin (V), diadinochrome (VI), peridinin (VII) and dinoxanthin (VIII).

The dehydration of sterols[15,16], amino acids[17], and phytol[18] occurs in a variety of marine environments and both chemical and biochemical mechanisms have been proposed. The dehydration of stanols to sterenes is structurally analogous to the dehydration of the secondary 3 or 3′ hydroxyl of carotenoid alcohols. The dehydration products of fucoxanthin (Fig. 3, IIIa, b) arise from loss of the tertiary 5′ hydroxyl group, with retention of the hydroxyl groups at both the 3 and 3′ positions. This suggests either that different processes exist for the dehydration of stanols and carotenoid alcohols, or there is a general process which displays an order of biochemical reactivity (for example, tertiary alcohols dehydrate faster than secondary alcohols). In the latter case we would expect to observe a sequential dehydration through the 3,5′ (or 3′,5′) didehydro and 3,3′,5′ tridehydro intermediates. The carotenoid mixtures in our samples contain ~100 components, of which only the 20 major components have been identified by our methods. Our analysis does not exclude the existence of more highly dehydrated metabolites in our samples.

In conclusion, we have observed ester hydrolysis and dehydration of fucoxanthin associated with particles collected in sediment traps. We propose a biochemically mediated transformation pathway (Fig. 4) which predicts that other carotenoids structurally similar to fucoxanthin (such as peridinin (VII) and dinoxanthin (VIII) from dinoflagellates) should undergo analogous transformations. We are conducting experiments with both long- and short-term sediment trap deployments, and direct collection of zooplankton faecal pellets to substantiate the proposed mechanisms.

This research was supported by the NSF, Division of Ocean Sciences, grant nos OCE 79-25352 and OCE 81-18436 and by contract no. N00014-74-CO-262 NR083-004 from the Office of Naval Research. Marine deposits 35,000–25,000 years old in the Chott el Djerid, southern Tunisia

G. W. Richards & C. Vita-Finzi

Department of Geography, University College, Gower Street, London WC1E 6BT, UK

The Chott el Djerid is a large, salt-covered depression in southern Tunisia (Fig. 1). The late nineteenth century idea that the basin had been invaded by the sea[1,2] has been superseded by the view that any Quaternary flooding of the Chott must have resulted from climatic changes, as the fossils found in its sediments are not exclusively marine and there is no indication of the fluctuations in sea level or of the crustal movements that would be required to fill and then empty the basin[2,3]. We report here evidence for a marine connection 35,000–25,000 years ago and show that it implies subsequent uplift by some 80 metres in an area long regarded as either stable[2] or prone to subsidence throughout the Quaternary[4].

Two sets of terraces border the Chott. The earlier terrace dates from Villafranchian (Lower Pleistocene) times. The younger terrace contains numerous shells of the bivalve *Cerastoderma* (= *Cardium*) *glaucum* (Bruguière) and a few of the gastropods *Melania tuberculata* (Müller) and *Hydrobia* sp. In the Tozeur area *Corbicula fluminalis* (Müller) is also present. The microfauna includes 14 species of marine foraminifera, predominantly *Ammonia beccarii* (d'Orb.), and three species of ostracoda (*Cyprideis* sp.)[5].

Radiocarbon ages ranging from 22,000 ± 800 to $32,400^{+4,100}_{-2,800}$ yr BP on shell samples obtained from the younger terrace by Page[6] supported previous estimates[2] of its age and confirmed that it formed at a time when sea level was lower than today. Flooding was thus ascribed to climatic oscillations whether in the guise of reduced evaporation and thence a rise in the water table[3] or of an increase in rainfall effectiveness[6]. The fauna appeared to be consistent with lacustrine conditions. *C. glaucum* can tolerate salinities of 3–60% (ref. 7). *M. tuberculata*, though sometimes washed onto modern beaches (as at Gabes), is essentially a freshwater species. Both species occur together with *Hydrobia* sp., *Corbicula africana* and other freshwater or brackish water organisms as well as Foraminifera in Quaternary lake deposits in Wadi Shati, south Libya[8,9].

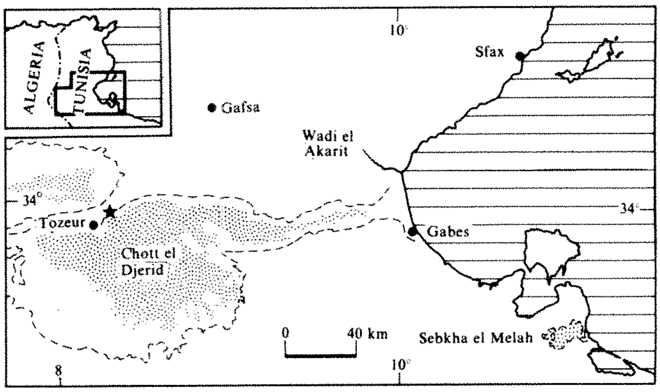

Fig. 1 Location map. Dashed line (after ref. 3) shows former extent of Chott el Djerid. Stipple indicates present-day salt-covered depressions. Star shows location of sites sampled for ^{14}C dating.

In March 1981 we found numerous rolled fragments of the oyster *Ostrea stentina* (Payr.) in one of the two type sections[3] in the younger terrace at Helba, 1.5 km north-east of Tozeur (Fig. 1) and 40 m above sea level. The deposits, which also contained abundant *C. glaucum* and a few specimens of *M. tuberculata*, consisted of a pebbly sand 30-cm thick resting unconformably on a southward-dipping clastic series ascribed to the Plio-Pleistocene[3]. What appears to be a regressive shoreline is exposed 5 m lower and some 200 m to the south-east of the first section. Here *O. stentina* is present within two gravel beds separated by 30 cm of massive sand containing a few *C. glaucum*. The upper bed is 5 cm thick and composed of large pebbles, the lower is a fine gravel at least 20 cm thick (Fig. 2).

Ostrea stentina is now found living in the intertidal zone at Gabes and elsewhere on the Tunisian coast. Unlike *C. glaucum* it has not been recorded from hypersaline or brackish lagoons[10]. Redeposition from older rocks is unlikely because the only oysters hitherto reported from the local Tertiary rocks are *O. multicostata* Desh., *O. punica* Thomas and *O. bellovacina* Lmk[11]. Transport by man cannot be ruled out, but it is improbable in view of the absence of complete shells and of artefacts or other evidence of human occupation at the two sections, and the lack of oyster shells from local prehistoric sites[12].

Radiocarbon ages were determined on oysters from the two exposures (Fig. 2) and also on a sample of *C. glaucum* from the upper exposure. No sample showed evidence of recrystallization when examined in thin section, and X-ray diffraction confirmed that the *C. glaucum* shells had retained their aragonitic composition. The stable isotope measurements (Table 1) and the good agreement with the ^{14}C ages previously reported[6] for the terrace are consistent with this view[13]. If one accepts that ~30,000-yr ago sea level lay 40 m below its present position[14], the beach deposits represent total emergence by 80 m and 75 m respectively, and hence uplift rates of 2.3–3.3 mm yr^{-1}. A sea level of −8 m as indicated by the sedimentary record beneath the Sebkha el Melah[15] (Fig. 1) would yield uplift rates of 1.4–1.7 mm yr^{-1}.

The results conflict with the evidence presented by geomorphologists for local stability[2] and by geologists for local sub-

Myoblasts from *Drosophila* wing disks can contribute to developing muscles throughout the fly

Peter A. Lawrence & Danny L. Brower*

MRC Laboratory of Molecular Biology, Hills Road,
Cambridge CB2 2QH, UK

In insect embryos groups of epidermal cells are already determined[1] to form particular compartments of the adult[2–4]. In *Drosophila* this determination is maintained through cell divisions, is stable to experimental interference[1,5,6] and is thought to depend on the activity of a particular class of homoeotic genes[4,7,8]. In contrast to our understanding of the ectoderm, we know little about determination of the mesoderm, which gives rise to the musculature. A recent study of cell lineage in the thorax of adult *Drosophila* has shown that the muscles of each segment are divided precisely into sets (P.A.L., in preparation). The dorsal and ventral muscle sets of the mesothorax probably derive from adepithelial myoblasts[9–11] in the wing and leg imaginal disk, respectively (P.A.L., in preparation). We describe here a new method of marking cells to trace myoblasts from the wing imaginal disk. We show that, when implanted, these mesodermal cells do not develop as they would *in situ* but instead contribute indiscriminately to developing host muscles. This result suggests that, whereas the ectodermal cells of the disk are committed to form a particular region of the adult, the mesodermal cells are not.

Portions of the wing imaginal disk from a wild-type larva were implanted into mature larval hosts. The donor cells carried the wild-type allele (sdh^+) at a locus which affects the enzyme succinate dehydrogenase; the host larvae were mutant (sdh^2/sdh^7) at this locus[12]. After metamorphosis the flies, as well as unimplanted controls of both genotypes, were histochemically stained for enzyme activity (see Fig. 1 legend). In the sdh^+ flies all muscles stained an intense dark blue, the stain being localized in the mitochondria. In the sdh^2/sdh^7 flies most muscles varied between pure white and pale blue in colour; 25 abdomens were examined, and dark blue muscles were seen only in the genital region. For this reason the genital muscles were not studied in the following experiments. Of 25 mutant thoraces sectioned, all muscles were white to pale blue.

A portion of the wild-type wing disk (**02** piece[13]; see Fig. 1) containing muscle precursors, the adepithelial cells, was implanted into 29 adults. In every case where the implant was retrieved it consisted of mesonotum and wing hinge structures, as expected[13], and was usually found in the posterior region of the abdomen. Only occasionally were implants associated with substantial numbers of adventitious muscle fibres and these could not be recognized as being of any particular type. Near the implant, some of the hosts showed abdominal muscles that were frequently (28/29 cases) stained dark blue (Fig. 2). These host muscles appeared normal in every other respect. The intensity of staining varied from fibre to fibre, densely stained fibres often being intermingled with unstained ones (Fig. 3). Further from the implant only occasional muscle fibres were stained, but these were prominent against the pale unstained background of the other fibres. The pleural membrane of the abdomen is covered with a delicate sheet of laterally oriented fibres, and these were also stained blue near the implant. In addition, the thoraces of many of the experimental flies (10/26) contained stained muscle fibres. For example, dark patches of stain were observed in both the direct and indirect flight muscles but were never found in the unimplanted controls (Fig. 4*a*, *b*).

There were three successful implantations of portions of the wing disk which probably do not contain adepithelial cells[14] (**58** pieces, Fig. 1). These implants formed the expected type of cuticle (wing blade and thoracic pleura[13]) and were not associated with any muscle fibres. All the host muscles of the abdomen and thorax were normal in structure and position and none stained dark blue.

Clonal analysis has shown that *sdh* alleles are cell-autonomous markers[12] which can be used in the muscles (P.A.L., in preparation). It is therefore highly unlikely that the succinate dehydrogenase activity was rescued other than by myoblast fusion. This is supported by the absence of staining when pieces of disk (**58**) lacking adepithelial cells are used. The sporadic staining of fibres far from the site of the implant also suggests that the myoblasts migrate and fuse with host muscles. The fact that pale, intermediate or dark fibres are closely intermingled suggests that none, a few or many donor cells may contribute to each fibre. It therefore seems that sdh^+ myoblasts, released from the wing imaginal disk, fuse indiscriminately with host muscles.

---

[*] Present address: Developmental Biology Center, University of California, Irvine, California 92717, USA.

0028–0836/82/010055—03$01.00

The adult muscles vary in many respects including sarcomere length, nuclear shape, mitochondrial size and fibre dimensions. However, when the host muscles of the abdomen and thorax stained blue, and were therefore at least partly composed of donor myoblasts, their structure appeared normal in every detail. There is evidence that the donor myoblasts *in situ* form only the dorsal muscle set of the mesothorax, which includes all the indirect flight muscles and a specific set of the direct flight muscles (P.A.L., in preparation). After implantation, they exhibit no such restriction and can apparently contribute to any host muscles with which they happen to fuse. Thus when removed from their normal environment, the adepithelial cells are not determined with respect to the type and location of the muscles they will form. By contrast, the fate of the epidermal cells is determined; when transplanted into mature larvae they differentiate according to their prospective fate[1,13].

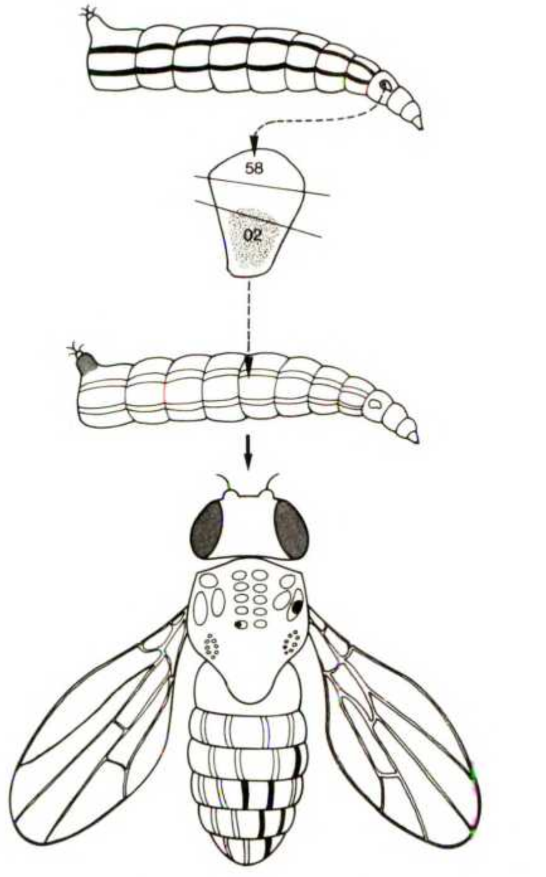

Fig. 1 Summary of the experimental procedure. A wing imaginal disk was dissected from a wild-type larva, and either the **58** or **02** piece[13] was sliced with tungsten needles and transplanted into the abdomen of a mutant host larva. After metamorphosis the host fly was stained for enzyme activity; dark fibres were found sporadically in the muscles, especially near the site of the implant. The shaded area in the disk shows the distribution of adepithelial cells, based on the binding patterns of fluorescent peanut lectin and a monoclonal antibody[14]. For marking the cells we used different alleles at the *sdh* locus[12]. Hosts were $b\ sdh^2/b\ sdh^7$ and therefore contain a thermolabile form of the enzyme succinate dehydrogenase[12]. After careful heating the succinate dehydrogenase activity disappears in sdh^2/sdh^7 muscles but survives in sdh^+ muscles. Donors were from a wild-type (Barton) stock. The *black* (*b*) mutation (see ref. 24) allowed the identification of the sdh^2/sdh^7 host larvae, which could be distinguished from their siblings by the dingy colour of the posterior spiracles. Enzyme activity, which is located in mitochondria, was specifically stained using the reduction of nitrobluetetrazolium[12]. Mature sdh^+ disk fragments were implanted into the abdomen of fully grown sdh^2/sdh^7 larvae by standard methods[25]. After metamorphosis the abdomen was dissected with the implant, heated to 52 °C in Ringer's solution for 15 min then stained for 2 h. The thoraces were heated to 53 °C in Ringer's solution for 15 min, stained for 2–3 days, embedded in paraffin wax and sectioned at 25 μm.

In contrast to earlier studies[15,16] it has been shown that the adepithelial cells do not arise directly from the disk epithelium (refs 17, 18 and P.A.L., in preparation) and fate-mapping studies of the adult flight muscles place their precursors in the mesodermal region of the blastoderm, at some distance from the presumptive epidermis[19]. The adepithelial cells can therefore be designated as mesoderm. Experiments on insect embryos have shown that when pieces of ectoderm are removed or damaged,

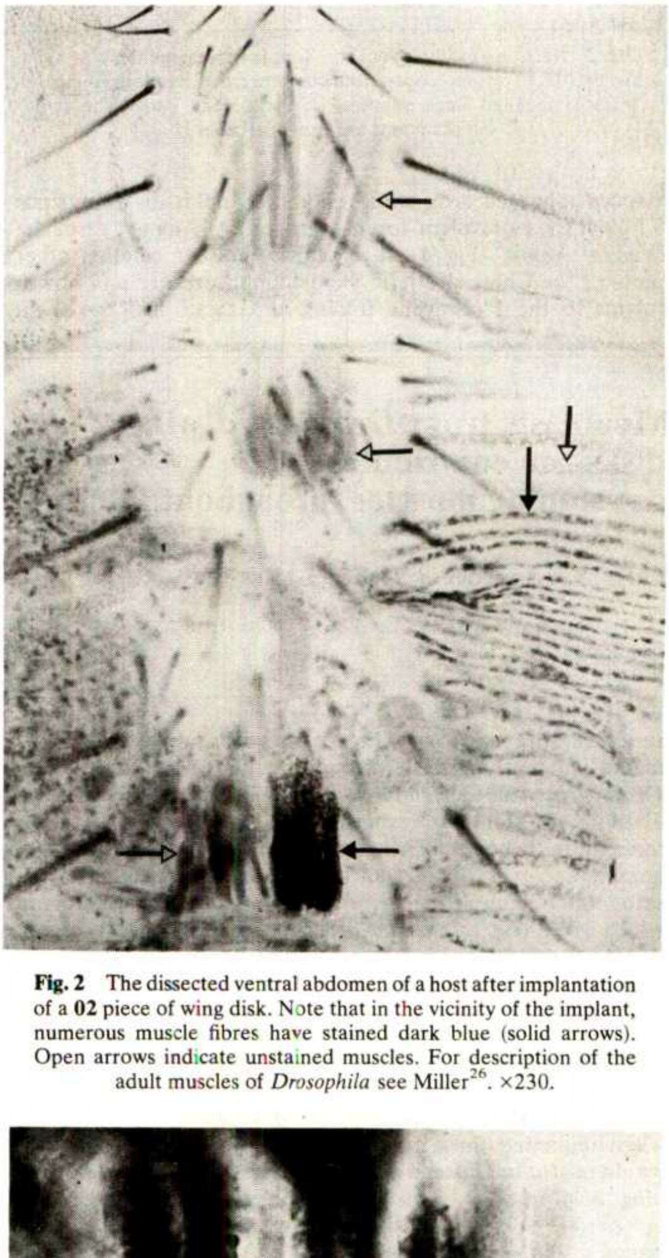

Fig. 2 The dissected ventral abdomen of a host after implantation of a **02** piece of wing disk. Note that in the vicinity of the implant, numerous muscle fibres have stained dark blue (solid arrows). Open arrows indicate unstained muscles. For description of the adult muscles of *Drosophila* see Miller[26]. ×230.

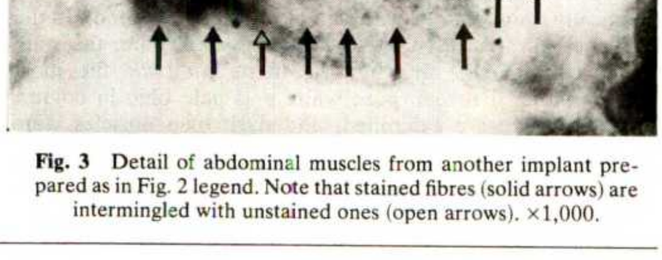

Fig. 3 Detail of abdominal muscles from another implant prepared as in Fig. 2 legend. Note that stained fibres (solid arrows) are intermingled with unstained ones (open arrows). ×1,000.

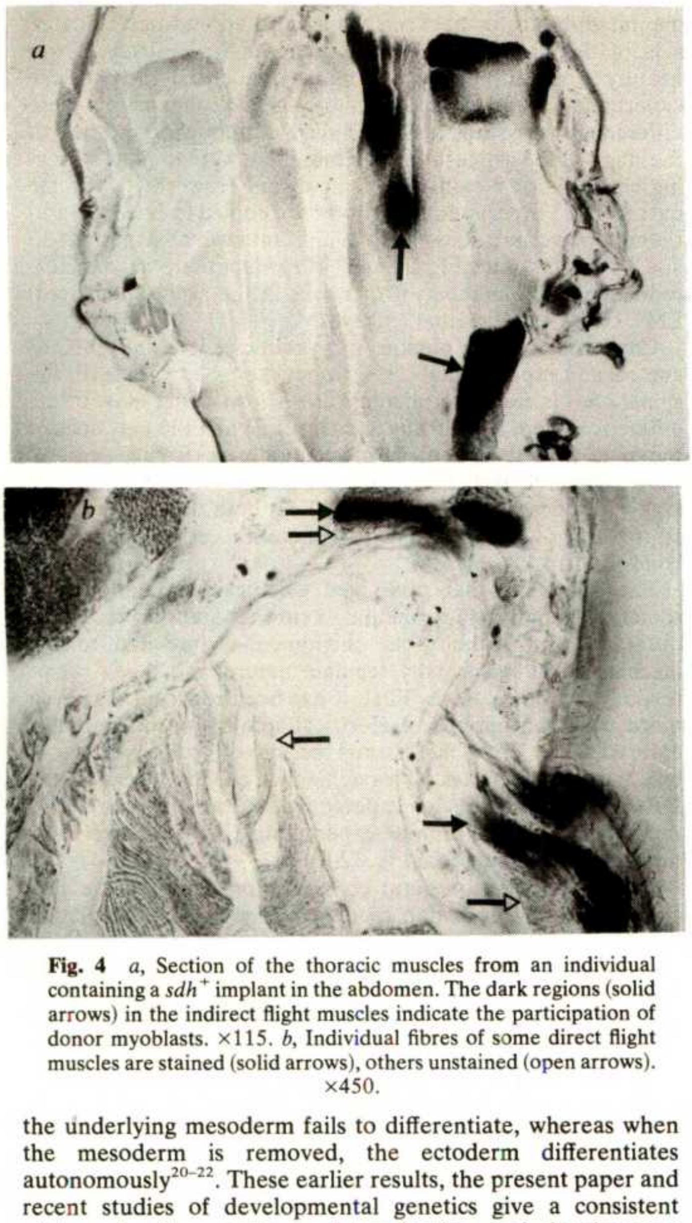

Fig. 4 *a*, Section of the thoracic muscles from an individual containing a *sdh*$^+$ implant in the abdomen. The dark regions (solid arrows) in the indirect flight muscles indicate the participation of donor myoblasts. ×115. *b*, Individual fibres of some direct flight muscles are stained (solid arrows), others unstained (open arrows). ×450.

the underlying mesoderm fails to differentiate, whereas when the mesoderm is removed, the ectoderm differentiates autonomously[20–22]. These earlier results, the present paper and recent studies of developmental genetics give a consistent picture. In the ectoderm, determination and development depend on genetic elements which are locally deployed in segmental and subsegmental compartments[4,7,8,23]. By contrast, the mesodermal cells do not appear to be as precisely determined, their development being at least partly dictated by the neighbouring ectodermal cells. Thus the cellular and genetic mechanisms of control seem to differ for the two germ layers.

We thank Mark Bretscher and Pat Simpson for discussion, Paul Johnston for assistance and Gary Struhl for help with the manuscript.

Electrical stimulation of hindlimb increases neuronal cell death in chick embryo

Ronald W. Oppenheim

Neuroembryology Laboratory, Department of Mental Health,
Anderson Hall, Dorothea Dix Hospital, Raleigh,
North Carolina 27611, USA

Ramon Núñez

Biological Sciences Group, University of Connecticut, Storrs,
Connecticut 06268, USA

The daily treatment of chick embryos with neuromuscular blocking agents during the period of massive naturally occurring death of spinal motoneurones (days 5–10) reduces the normal loss of these cells[1,2]. Because both pre- and postsynaptic blocking agents have this effect[3], the cause seems to be related to a reduction in synaptic and/or muscular activity. If this interpretation is correct, an experimentally induced increase in nerve or muscle activity (and/or an increased activation of acetylcholine receptors, AChR), during the normal cell death period should accelerate or enhance the loss of motoneurones. Consistent with this prediction, we have found that daily treatment with the nicotinic receptor agonist, carbachol, or with the anticholinesterase (anti-ChE) agent, eserine, leads to a significant enhancement of cell death of spinal motoneurones[3]. However, because in the same study other related agents (for example nicotine) failed to alter normal cell death, we believed that a different approach might provide a better test of our prediction. We now report that short-term continuous electrical stimulation of the hindlimb (the musculature and nerve trunks) initiated at any time between stages 31 (day 7) and stage 34 (day 8) results in a significant reduction in the number of healthy motoneurones and an increase in the number of pyknotic (degenerating) motoneurones in the lumbar lateral motor column (LMC). As the number of pyknotic cells in the dorsal root ganglia (DRG) is unaltered, this effect seems to be specific to motoneurones.

White Leghorn chick embryos were treated with curare, α-bungarotoxin (α-BTX) or saline as previously described[2]. Briefly, beginning on day 5, 100–200 μl of a curare (2–2.5 mg per embryo), α-BTX (75 μg per embryo) or 0.9% saline solution was injected daily onto the vascularized chorioallantoic membrane (CAM). About half the embryos in each group (saline and curare or α-BTX) were used for electrical stimulation while half were subjected to sham procedures. The curare and α-BTX treatment was associated with a significant reduction in the rate of spontaneous neuromuscular activity (embryonic motility)[1,2]. Data from the curare and α-BTX embryos were pooled (curare/α-BTX). To gain access to the embryo's leg, a relatively large lateral window was made in the shell, and the CAM and amnion were cut, avoiding most blood vessels. In all cases, the right leg was used for both the experimental (stimulation) and sham procedures. Stimulation suction electrodes (2.5 mm tip diameter), made from polyethylene tubing, were filled with a saline solution and held in a micromanipulator for attachment to the thigh region of the leg. The leg of the embryo was stabilized by either pulling it out of the amniotic fluid and placing it on top of the CAM or by securing it with a hair loop which was attached to the shell. Despite these

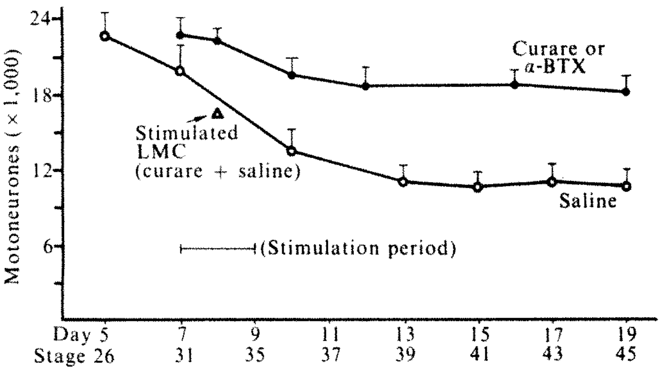

Fig. 1 The average number of motoneurones (±s.d.) in the lumbar LMC of saline (○) and curare/α-BTX (●) treated embryos. Embryos were treated as described by Pittman and Oppenheim[2]. △, The average number of motoneurones in the right LMC of all experimental embryos in the present study (saline plus curare-α-BTX treated, stages 31–35) following electrical stimulation of the right hindlimb at various times during the stimulation period (—) (see text for details).

precautions, the suction electrode occasionally became detached from the leg. Consequently, the embryos were checked every 3–4 h and in those cases where the electrode had lost contact it was re-attached. Following the attachment of the electrode, the window in the egg was closed with Parafilm and the egg placed in a temperature-controlled environment of 33–35 °C. Electrical pulses were delivered via a Grass stimulator (duration 0.6 ms, rate 0.5–1.0 s^{-1}). The stimulus intensity was adjusted to 1.5–2.0 times the minimal intensity required to produce visible contractions of the leg. It was sometimes necessary to readjust the stimulus intensity during the experiment. The sham procedure was similar in all respects to that described above except that the stimulator was not turned on. At the end of the stimulation period, the surviving embryos (<12% of the total) were killed, staged[4], fixed and processed for histological examination. The histological procedures and the methods for counting healthy and pyknotic neurones were as previously described[5,6] (also see Fig. 2*b* legend).

From a total of 210 embryos, 24 survived and were killed after 5–22 h of treatment (mean 12.8 and 14.3 h for experimental and control respectively). Of these, nine (five experimental, four control) were found to have various degrees of limb necrosis caused either by the manipulation involved in attaching the electrodes or by electrolytic damage. Two animals in each group (experimental and control) had extensive necrosis of the leg and were excluded from further analysis. (Compared with the other experimental cases these embryos had more than double the number of pyknotic neurones in both the lumbar DRG and LMC.) The other five embryos (three experimental, two control) had only a small amount of necrosis, limited to the foot region, and thus are included in the data analysis. With these exceptions, based on a preliminary light microscopic analysis of limb musculature, there were no obvious differences in muscle histology between the experimental and control limbs. Most of the experimental embryos used for analysis were still showing visible limb contractions in response to the electrical stimulation at the end of the experiment.

Figure 1 shows an analysis of the changes in motoneurone number during development of the lumbar LMC of control saline and curare/α-BTX treated embryos, together with the pooled data on healthy neurones from the electrically stimulated embryos. It can be seen that both stimulation periods (stages 31–33 and 34–35) fall within the time span of massive naturally occurring cell death.

Because no differences were found in the number of either healthy or pyknotic motoneurones between the right and left LMC of both the saline and curare/α-BTX control (sham) embryos, the data from the two sides were pooled for all subsequent comparisons with the experimental, stimulated embryos. In all comparisons between the control and experimental embryos, or between the stimulated and unstimulated side of the experimental embryos, there were always fewer healthy motoneurones in the right (stimulated) LMC of the experimental cases (Fig. 2*a*). In most of the comparisons these differences were statistically significant, although in the case of the stage 31–33 saline-treated group there were too few surviving embryos for a statistical comparison. However, when the data from all experimental embryos are pooled (saline + curare) the differences are statistically significant both at stages 31–33 and 34–35 ($P < 0.01$, Fig. 2*a*). In both groups there was a ~20% reduction in the number of neurones in the right (stimulated) LMC of the experimental embryos.

Comparison of the number of pyknotic cells in the LMC of control and experimental cases, or between the two sides of the spinal cord in the experimental cases showed that most of the differences were statistically significant. When the two sides of the spinal cord of the pooled experimental cases (saline + curare) were compared statistically, the differences were found to be highly significant ($P < 0.01$, Fig. 2*b*). At both stages there were approximately twice as many degenerating cells in the stimulated (right) LMC.

The possibility that prolonged electrical stimulation may somehow be lethal to developing neurones and that the effect observed is a pathological phenomenon unrelated to the mechanisms that normally regulate natural cell death seems unlikely for two reasons. First, it has been reported that even more polonged periods of electrical stimulation of the chick embryo wing, after the normal period of extensive loss of brachial motoneurones[7], does not induce cell loss[8]. Second, the DRG cells, which are also undergoing natural cell death during the stages examined in these experiments[5], were unaffected by the electrical stimulation (Fig. 2*b*).

An additional procedural consideration concerns the rate and pattern of stimulation used here. The rate of stimulation

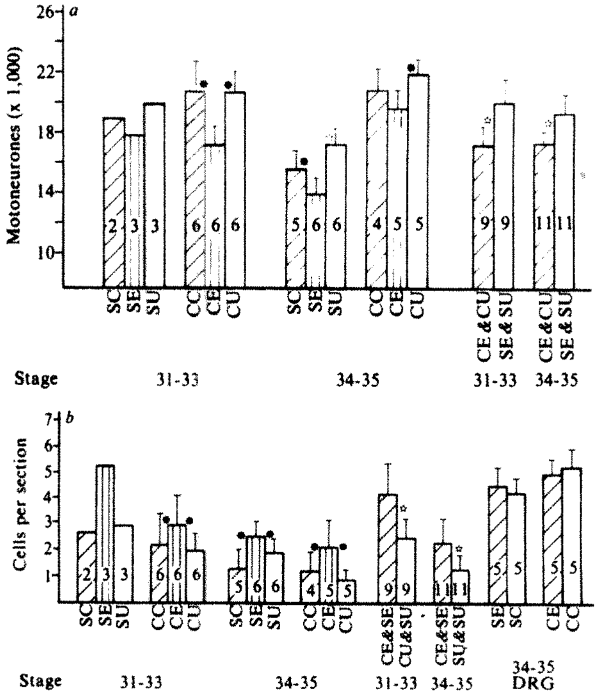

Fig. 2 The number of 'healthy' motoneurones (mean ± s.d.) (*a*) and of dying (pyknotic) motor and sensory neurones (mean ± s.d.) (*b*) in the lumbar LMC following electrical stimulation of the right hindlimb at stages 31–33 or 34–35. SC, saline control; SE, saline experimental (stimulated or right) LMC; SU, saline unstimulated (left) LMC; CC, curare/α-BTX control; CE, curare/α-BTX experimental (stimulated or right) LMC; CU, curare/α-BTX unstimulated (left) LMC. CE & SE and CU & SU represent pooled data from the saline plus the curare/α-BTX treated embryos. ★ $P < 0.05$; ☆, $P < 0.01$, Mann–Whitney tests, one-tailed. All statistical comparisons are relative to the experimental (stimulated) group, SE or CE. Sample size is as indicated in the bars.

(0.5–1.0 s^{-1}) was considerably higher than the normal rates of limb motility at these ages, which is between 6 and 12 per min (ref. 2). Although we chose a high rate of stimulation to increase our chances of finding an effect, we cannot rule out the possibility that the results reflect non-physiological conditions. However, in adult mammals a wide variety of stimulus rates and patterns are effective in maintaining the normal properties of denervated muscle[9]. We are now attempting to determine the effects of differing rates and patterns of stimulation on motoneurone death in the chick embryo.

We have suggested a model for explaining the role of activity in the regulation of neuronal cell death[1,2,10]. Briefly, we proposed that during embryonic development, synaptic and/or muscle activity regulates those events which lead to a reduction in the availability of a trophic substance and/or in the level of AChR in muscle. This reduction would limit the number of synaptic sites that can be formed on a muscle cell, leading, in turn, to competition between neurones for a relatively fixed number of synaptic sites (and/or for a limited supply of trophic substance), in which competition the losers undergo cell death. We suggest that neuromuscular blockade suppresses and electrical stimulation enhances this series of normal events.

Although many questions remain unanswered concerning the specific cellular and molecular events by which neuromuscular interactions regulate the number of motoneurones that survive the cell death period, the present findings provide additional support for our contention that synaptic and/or muscular activity is involved. In view of the increasing evidence that many other properties of the neuromuscular system depend on physiological activity for their normal differentiation and maintenance[10–15], it is perhaps not surprising that motoneurone cell death should now be added to this list.

Significance of the potassium signal from neurones to glial cells

V. W. Pentreath & M. A. Kai-Kai

Department of Biology, University of Salford, Salford M5 4WT, UK

Neurones transmit signals to glial cells by releasing potassium into the intercellular spaces during nerve activity, simultaneously depolarizing their membrane potential[1]. It is thought that the glial cells may respond metabolically or trophically to the released K, and that they may also take up excess K, thereby protecting the neurones against perturbations in the extracellular concentration of this ion[2,3]. We have studied metabolic interactions between the two cell types in leech and snail ganglia using a recently discovered application[4,5] of the radioactively labelled 2-deoxyglucose (2-DG) technique[6]. This approach derives from the finding that ^{3}H-2-DG is partially and selectively metabolized into glycogen within nervous tissue, and thus can be used as a sensitive, specific marker for mapping sites of glycogen synthesis and distribution in nervous tissue[4,5]. In the leech and snail ganglia, the large size of the neuronal perikarya, together with the grouping of the glial cells around them and the location of the axonal and dendritic processes in the core of the ganglia, allows the distributions of the labelled glycogen in the different cell types and their processes to be resolved by light and electron microscope autoradiography[7,8]. Here we describe how in both animals, antidromic stimulation of nerves entering the ganglia increased the incorporation of ^{3}H-2-DG into glycogen in glial cells surrounding the activated neurones. Increased extracellular K had a similar effect, which was maximal for a K concentration ~4 mM above normal. We therefore conclude that neuronal activation causes a K-mediated increase in ^{3}H-2-DG uptake and synthesis into glycogen by the satellite glial cells.

In the technique used, incorporation of ^{3}H-2-DG into 2-deoxyglycogen proceeds analogously to the glucosyl transfer from uridine diphosphate glucose (UDPG) into glycogen; the enzymes for glycogen synthesis are relatively nonspecific to the presence or absence of the hydroxyl group at C-2 of the glucose unit. The labelled 2-deoxyglycogen is able to withstand autoradiographic processing with aqueous media, whereas unmetabolized 2-DG and 2-DG-6-PO_4 are washed out. The resulting autoradiographs show the distribution of 2-DG incorporated into glycogen, which corresponds to the amounts of endogenous glycogen.

Isolated abdominal ganglia of the leech, *Haemopis sanguisuga*, and buccal ganglia of the snail, *Planorbis corneus*, were immersed in appropriate salines[9,10] containing 5–10 μM 2-deoxy-D[1-^{3}H]glucose (15.0 Ci $mmol^{-1}$; Radiochemical Centre, Amersham) and incubated at room temperature for 5–60 min. The effects of increased nerve activity were studied by stimulating nerves from the ganglia with suction electrodes, using pulses of 2.5–5.0 ms duration, 1–10 V at 5 Hz for between 10 min and 1 h. The uptake and metabolism of 2-DG in the presence of increased extracellular K were measured by incubating ganglia in saline solutions containing additions of 4 mM and 15 mM K at room temperature for 15 min to 1 h. Following the load periods with ^{3}H-2-DG, all experimental tissues were analysed by three procedures. First, the levels of radioactivity in the ganglia were measured by liquid scintillation counting. Second, the amounts of ^{3}H-2-DG incorporated into glycogen were assessed by the method of Mordoh *et al.*[11] (this method extracts high molecular weight glycogen in a pure form; the glycogen is not degraded and loss of label is minimized). Third, the distributions of labelled glycogen in the ganglia were determined by light and electron microscope autoradiography of tissues fixed with aldehyde and processed with aqueous media for histology[4].

During 15–60 min exposure to ^{3}H-2-DG, the ganglia of *Haemopis* and *Planorbis* progressively accumulated ^{3}H-2-DG at a rate of 0.13 and 0.16 nmol per g nervous tissue per min respectively. After 1 h, 4–5% of the ^{3}H-2-DG was recovered in the high molecular weight glycogen fraction from *Haemopis*, and ~1% in the fraction from *Planorbis* (Fig. 1*b*). The autoradiographic pattern of glycogen labelling observed by light microscopy differed in the two species. In *Haemopis*, small areas of radioactivity were located in a narrow band of the peripheral cytoplasm of most neuronal perikarya, often in clumps of 1.5 μm diameter (Fig. 2*a*); axonal and dendritic processes were unlabelled. The giant glial cells[7,8] surrounding the perikarya were labelled. In *Planorbis*, groups of neurones were selectively and heavily labelled after 1 h exposure to ^{3}H-2-DG (Fig. 2*c*). Serial section analysis revealed that the radioactivity was distributed evenly throughout the axonal and dendritic processes. The glial cells surrounding the neurones were not labelled or only weakly. Electron microscope autoradiography showed that

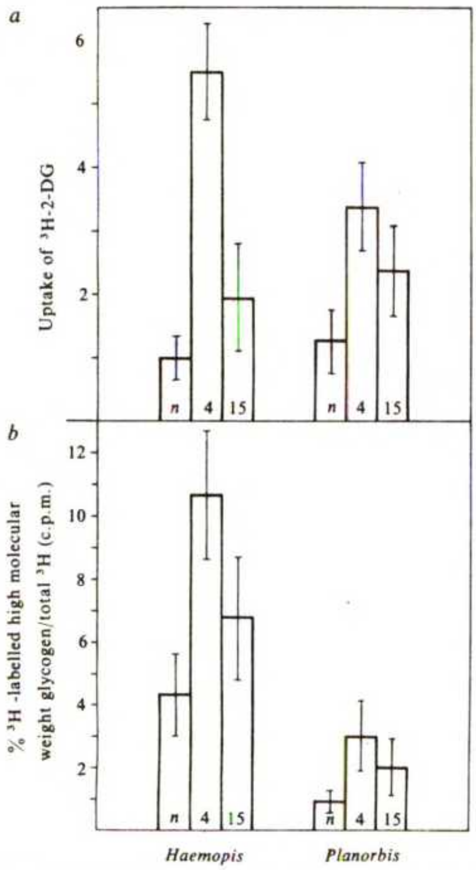

Fig. 1 Stimulation of ^{3}H-2-DG uptake (*a*) and incorporation into high molecular weight glycogen (*b*) in abdominal ganglia of *Haemopis* and buccal ganglia of *Planorbis*. Each set of histograms shows results for normal saline K concentrations, *n* (4.0 mM for *Haemopis*; 1.3 mM for *Planorbis*), and for salines containing additional 4.0 mM and 15.0 mM K, added in the form of sulphate ions. Results are the means of three experiments in each case; bars indicate s.e. *a*, The ganglia were rinsed in saline (1 min) after the load period, homogenized in a tissue solubilizer (NCS; Radiochemical Centre, Amersham) and counted by liquid scintillation. All counts were corrected against blank controls (ganglia processed in parallel but without exposure to radioactive tracer) and for quenching (generally <1% using NCS solubilizer) by conventional methodology. The uptake of radioactivity by a unit weight of ganglia is expressed (in c.p.m.) relative to the uptake by *Haemopis* ganglia in normal saline (unity). *b*, After the load period, high molecular weight undegraded glycogen was separated by a method similar to that described elsewhere[11]. Ganglia were homogenized in ~3 vol 3% $HgCl_2$ and centrifuged at 2,000*g* for 5 min. The supernatant was added to ~2 vol of 95% ethanol, and the resulting precipitate separated by centrifugation (2,000*g* for 5 min). The precipitate was redissolved in water (0.5 ml) and the solution centrifuged again. The resulting supernatant was mixed with 2 vol of ethanol, and the sample was centrifuged at 2,000*g* for 10 min. The final sediment (the high molecular weight glycogen) was dissolved in NCS solubilizer and the radioactivity measured by liquid scintillation counting. Counts are expressed as percentages of the total radioactivity recovered in all the fractions. The lower molecular weight glycogen is not readily extracted by this procedure, thus the total percentages of labelled glycogen are likely to be higher.

the differences in labelling patterns were correlated directly with differences in the distribution of glycogen in the two species[4]. In *Haemopis*, aggregates of glycogen particles were frequently contained within glial processes extending into the neuronal somata (Fig. 3).

Stimulation of nerves (1 h at 5 Hz) entering the ganglia of both species resulted in an approximate fivefold increase in accumulated radioactivity as measured by liquid scintillation. However, the incorporation of ^{3}H-2-DG into glycogen was not proportional to this increase; the levels of labelled high molecular weight glycogen extracted from the tissues were increased 2.3–3.2 times (*Haemopis*, mean increase = 3.2 ± 1.4, 4 experiments; *Planorbis*, mean increase = 2.3 ± 1.1, 4 experiments). When the distribution of labelled glycogen was studied by light microscope autoradiography, it was found that the labelling of the neurones, particularly their perikarya, was increased in both species, but a striking feature was the increased grain density in the glial cells surrounding the perikarya (Fig. 2*b*, *d*). Thus neuronal activation caused an increase in uptake of ^{3}H-2-DG by the nervous tissues, and to a lesser extent its incorporation into high molecular weight glycogen. As the neurones were stimulated via nerves outside the ganglia, the increased levels of glycogen in the glial cells inside the ganglia resulted indirectly from the neuronal activation.

There is evidence that extracellular [K] may normally be increased by 4 mM during maintained nerve activity in leech abdominal ganglia[12], and by 4–8 mM in the cat cortex[13]. Higher experimental levels of extracellular K produce increased depolarization of glial cells, but it is unlikely that such levels are of normal physiological significance[3]. The role of K in mediating the activity-induced increase in ^{3}H-2-DG uptake and incorporation into glycogen was investigated by incubating ganglia in saline containing ^{3}H-2-DG with elevated K levels and measuring the uptake of radioactivity and its conversion to glycogen. Other ganglia incubated in parallel were processed for autoradiography. Exposure of *Haemopis* ganglia to a wide range of extracellular [K] from the normal level (4.0 mM) to 40 mM in 1 mM increments for 1 h revealed a maximal increase in ^{3}H-2-DG uptake (about five times) when the increase was 3–5 mM (Fig. 1*a*). Higher values of extracellular K gave lower increases in 2-DG uptake, which varied between 1.5 and 2.2 times, although increases of up to four times were occasionally ob-

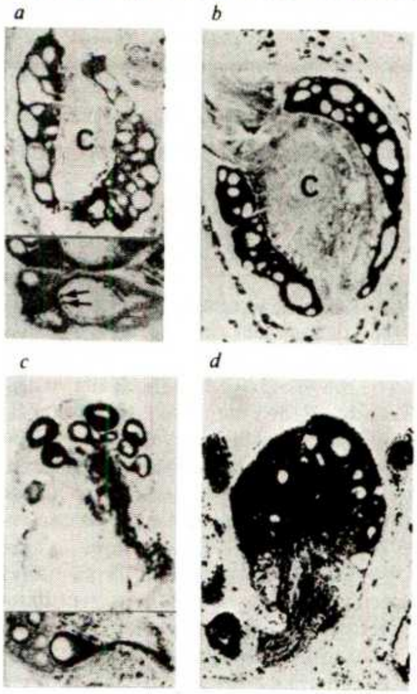

Fig. 2 Distribution of labelled glycogen in the abdominal ganglion of *Haemopis* (*a*, *b*) and the buccal ganglion of *Planorbis* (*c*, *d*). The ganglia were exposed to ^{3}H-2-DG for 1 h, then processed by aldehyde fixation, water–ethanol dehydration and wax sectioning[4]. The autoradiographs were prepared by coating the sections with Kodak AR 10, storing for 2 weeks, and then developing in Kodak D-19. *a*, Top: the labelled glial cells surround the neuronal perikarya which are located in the cortex of the ganglion. The core of the ganglia (C) contains large numbers of axonal and dendritic processes, but few glial cell processes[7]; bottom: at higher magnification grain clumps can be distinguished in the peripheral somatoplasm of some neurones (arrows). Many of these correspond to the glial invaginations visualized by electron microscope autoradiography (Fig. 3). *b*, Section of a ganglion stimulated antidromically via the abdominal connective at 5 Hz for 1 h in the presence of ^{3}H-2-DG. Note the heavy labelling of the glial cells. *c*, Labelled neurones in a buccal ganglion of *Planorbis*: top, a group of labelled neurones which project into the neuropile of the ganglion; bottom, a large neurone cut in section to illustrate the equal distribution of labelled glycogen in the peripheral cytoplasm of the cell body and its axon. The branching patterns of the main axonal processess of the labelled neurones were mapped by comparison with adjacent serial sections. *d*, Section of buccal ganglion stimulated antidromically via the cerebro-buccal connective at 5 Hz for 1 h. Note the intense labelling of the glial cells which surround the neuronal perikarya, and increased labelling of the neurones. In both species the ganglia are avascular, but there are no restrictive barriers to the access of small molecules[1]. All magnifications, ×100, except for *a*, bottom (×320) and *c*, bottom (×175).

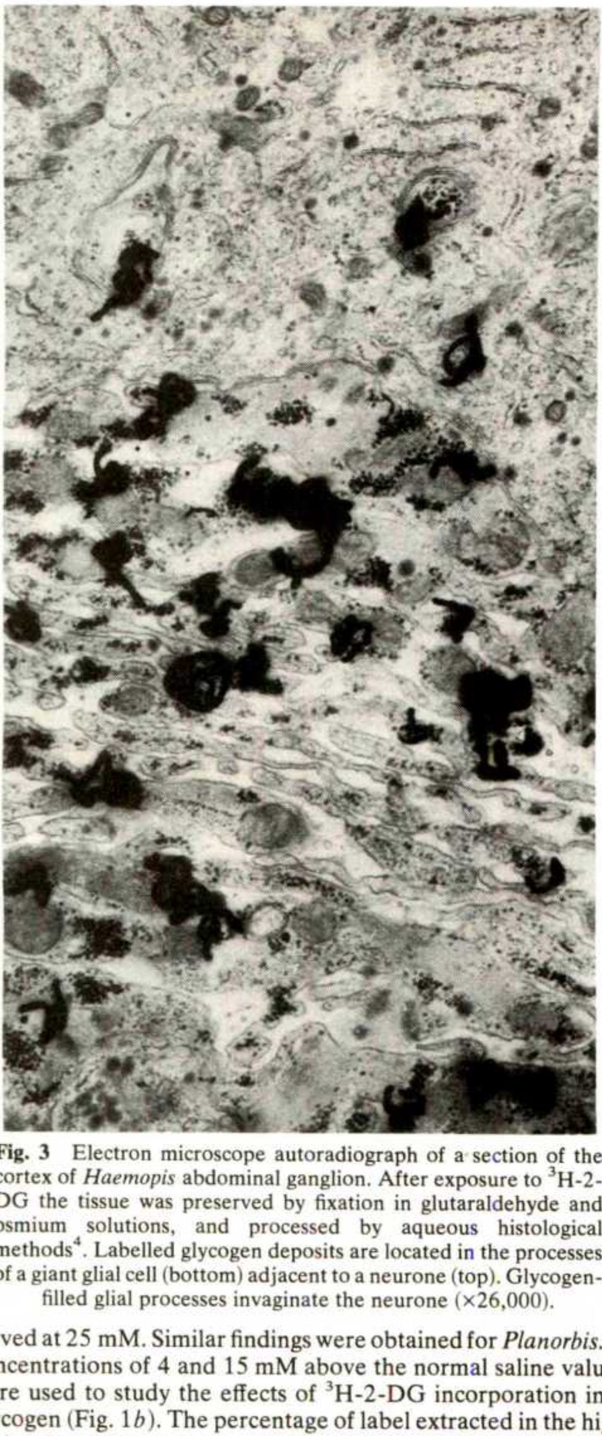

Fig. 3 Electron microscope autoradiograph of a section of the cortex of *Haemopis* abdominal ganglion. After exposure to ^{3}H-2-DG the tissue was preserved by fixation in glutaraldehyde and osmium solutions, and processed by aqueous histological methods[4]. Labelled glycogen deposits are located in the processes of a giant glial cell (bottom) adjacent to a neurone (top). Glycogen-filled glial processes invaginate the neurone (×26,000).

served at 25 mM. Similar findings were obtained for *Planorbis*. K concentrations of 4 and 15 mM above the normal saline values were used to study the effects of ^{3}H-2-DG incorporation into glycogen (Fig. 1*b*). The percentage of label extracted in the high molecular weight glycogen was increased 2.5-fold for *Haemopis*, and 3-fold for *Planorbis* at 4 mM K, and to a lesser extent at 15 mM K. Autoradiographic analysis showed that 4 mM K (1 h exposure) produced labelling of glial cells that was comparable to the effects of electrical stimulation. A concentration of 15 mM caused some increase in the grain density overlying the glial cells, and also over the neurones. Extracellular recording experiments showed that the 4 mM increase in [K] caused no significant increases in the electrical activity of neurones in either species. Activity was initially greatly enhanced, but not maintained, at [K] >12 mM.

These results provide direct evidence that increased neuronal activity causes a significant potassium-mediated increase in ^{3}H-2-DG uptake and incorporation into glycogen by the satellite glial cells. The similarity of the findings in both leech and snail ganglia indicate that this may be a general neurone–glial property. Both electrical stimulation and increased extracellular [K] increased the amounts of ^{3}H-glucose incorporated into glycogen in leech and snail ganglia (our unpublished observations), however the sites could not be resolved accurately by autoradiography as the label was also extensively incorporated into proteins and lipids.

The enzyme systems that synthesize and catabolize glycogen in mammalian brain are the same as those in other tissues[14,15], although they appear to differ in certain kinetic properties and modes of regulation[16]. It is evident that glycogen metabolism within the central nervous system must be controlled locally, because circulating hormones cannot pass the blood–brain barrier. There are no data on possible modulatory roles of K or K-induced depolarization on glycogen metabolism in nervous tissue. However, the selective stimulatory effects of K on glycogen formation in liver are well established [17,18]. Glial cell membranes are selectively permeable to K[1] and the K-mediated promotion of glycogen synthesis in glial cells caused by localized neuronal activity could provide a significant mechanism for ensuring continued energy supplies during any subsequent intense activity if local blood–glucose levels fell or were inadequate.

Depletion of substance P-containing axons in substantia gelatinosa of patients with diminished pain sensitivity

John Pearson*, Leslie Brandeis* & A. Claudio Cuello†

University of Oxford, Oxford OX1 3QT, UK

Substance P is an undecapeptide which may be involved in transmission of nociceptive information at synapses of primary sensory neurones[1,2]. It occurs in 10–20% of rat dorsal root ganglion neurones[3,4]. Small substance P-immunoreactive (SP-IR) axons from dorsal root ganglia enter the spinal cord and form a dense terminal network in the substantia gelatinosa of the rat dorsal horn[3]; analogous fibres from the trigeminal ganglion terminate in the substantia gelatinosa of the spinal trigeminal tract of the medulla oblongata[4,5], while sensory axons travelling via the petrosal and nodose ganglia terminate in the tractus solitarius of the medulla[5–8]. Substance P is also present in human spinal cord and pallido-nigral system[9–12]. In addition to sympathetic and parasympathetic abnormalities, patients with familial dysautonomia (the Riley–Day syndrome) have severe diminution of temperature and pain sensitivity, reduced populations of primary sensory neurones and small Lissauer's tracts[13]. It was thus postulated that a diminution of primary substance P axons might be demonstrable using immunocytochemistry. We report here the presence of anatomically discrete depletion of substance P immunoreactivity in the substantia gelatinosa of spinal cord and medulla of patients with familial dysautonomia. The results are consistent with the hypothesis that substance P is involved in the transmission of impulses related to pain.

0028-0836/82/010061—03$01.00

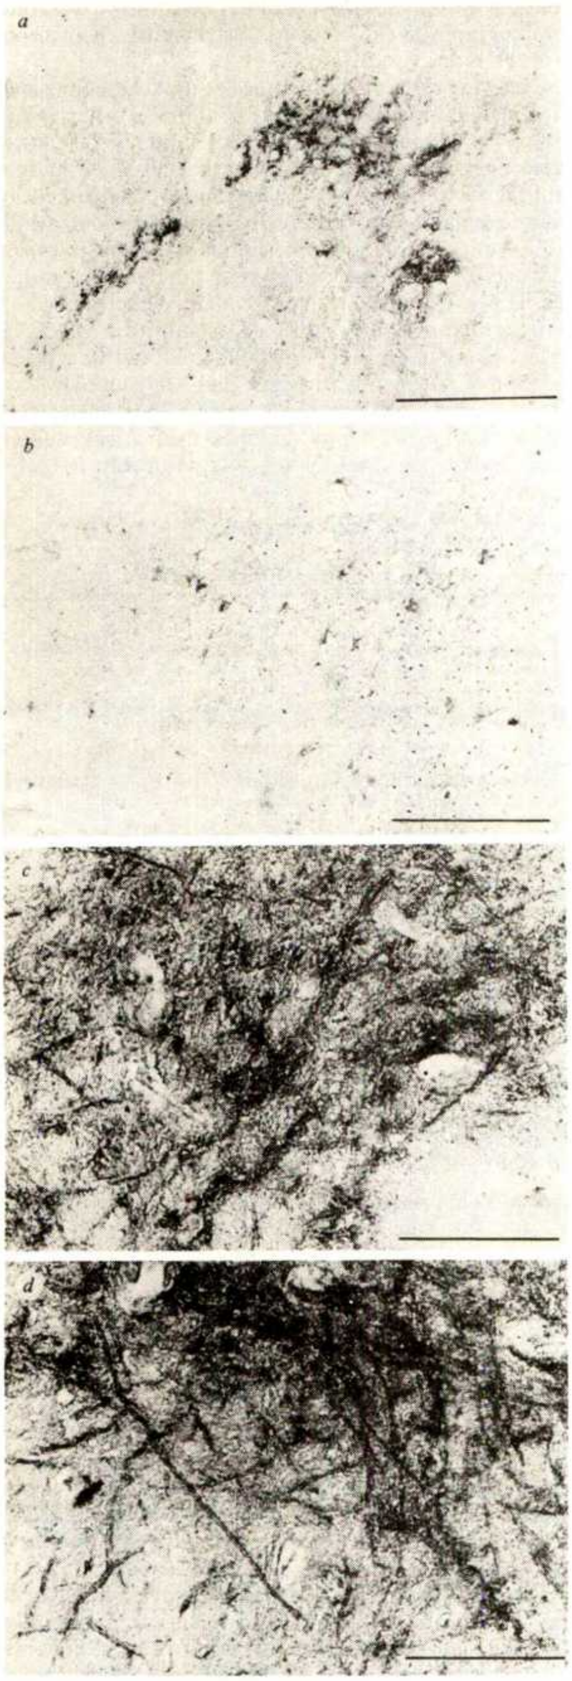

Fig. 1 The substantia gelatinosa of the control spinal cord (*a*) contains multiple substance P-immunoreactive (SP-IR) axons and their terminals, which form a distinct cap over the dorsal grey horn; no such cap is visible in the familial dysautonomia patient's spinal cord (*b*). The substantia nigra of both the control (*c*) and the patient (*d*) contain similar amounts of SP-IR fibres. Scale bars, 100 μm.

The present studies used a well characterized monoclonal antibody (NCI/34HL) to substance P[14]. Thus, it does not cross-react with any other known mammalian neuroactive peptide, stains substance P in brain regions shown to contain the peptide by bioassay, and stains the peptide which accumulates proximal to peripheral nerve ligatures and which can be independently identified on Sephadex columns[14]. The antibody was used with the peroxidase–antiperoxidase (PAP) technique of Sternberger[15]. Staining controls included normal serum and antibody adsorbed with substance P, neither of which gave any positive reaction. Test tissues used were from five patients aged 14, 15, 17, 18 and 22 yr, diagnosed as having Riley–Day syndrome at the Dysautonomia Treatment and Evaluation Center of New York University Medical Center. The diagnosis was confirmed at autopsy by a characteristic combination of defects in the tongue, sympathetic ganglia and dorsal root ganglia. Spinal cord and brain stem sections were made from archival blocks of paraffin-embedded tissue which had been fixed in 10% formalin. Storage times for patient and control tissues were similar.

In contrast to the controls, which showed large concentrations of SP-IR terminals in the substantia gelatinosa of spinal cord and medulla oblongata (Fig. 1*a*), there was almost complete absence of such terminals from these regions in all patients with familial dysautonomia (Fig. 1*b*). Some of the few remaining SP-IR axons observed may have been derived from the brain stem, as studies in other species[1,2] have shown the presence of SP-IR axons in this region. Patients did not differ from controls in the density of SP-IR axons in the substantia nigra (Fig. 1*c*,*d*). Immunoreactive axons were also readily demonstrable in the tractus solitarius of patients. It is not possible to obtain good staining of the small quantities of substance P normally present in the perikarya of primary sensory neurones of monkey or man, and colchicine pretreatment is necessary to cause sufficient accumulation of the peptide in most lower animals. We were therefore unable to demonstrate directly depletion of primary sensory substance P-containing neurones in the patients. Nevertheless, we have previously demonstrated severe losses of sensory axons, especially those of small diameter, in familial dysautonomia and have shown that severe deficits of dorsal root ganglion neurones occur in young patients[13]. Depletion of spinal dorsal horn neurones has not been demonstrated, and the fact that spinal dorsal column fibres only diminish as sensory neuronal loss continues into adulthood[13] indicates that initial deficits are mainly among neurones projecting onto the substantia gelatinosa and other parts of the dorsal grey. Small-calibre sensory axons projecting onto the substantia gelatinosa and containing substance P have been suggested as being involved in processing of pain-related impulses[1,2]. The coincidence of analgesia, loss of sensory neurones and small diameter axons projecting onto the substantia gelatinosa, and severe diminution of dorsal horn substance P immunoreactivity in familial dysautonomia support this idea. However, it does not prove the case because other sensory modalities, notably those related to temperature, are also attenuated in familial dysautonomia; other putative neurotransmitters yet to be examined may be found to be decreased in the disease.

The persistence of some substance P in axons of the tractus solitarius might be attributed to sources within the central nervous system. Alternatively, there might be less sensory neuronal loss in cranial ganglia, some of which are of placodal origin, than in dorsal root ganglia, which are of neural crest origin. No formal neuronal counts have been made of patients' cranial ganglia.

Although immunocytochemistry cannot definitively demonstrate the absence of an antigen, there is no doubt that the amount of substantia gelatinosa axon substance P in the patients was far below normal. That this was not an artefact of autolysis is indicated by comparison with controls in which the postmortem intervals were generally longer than those of the patients but in which substantia gelatinosa SP-IR axons were readily demonstrable. Furthermore, substance P has been demonstrated to have excellent postmortem stability[12,16,17]. Finally, the ready detection of SP-IR axons in the tractus solitarius and substantia nigra of the patients provides excellent internal control both of staining efficacy and postmortem preservation of the peptide. The fact that SP-IR is normal in these structures indicates that familial dysautonomia does not involve a generalized defect in substance P synthesis.

Our data indicate a need for prospective studies of substance P levels in fresh wet tissue from patients. They also demonstrate the usefulness of immunocytochemistry in the microscopic study of human neurobiology and in the detection of deficits in chemically defined neurones in human disease.

S-100 protein in human chondrocytes

K. Stefansson*, R. L. Wollmann*, B. W. Moore† & B. G. W. Arnason*

* Departments of Pathology and Neurology, University of Chicago,

Medicine, St Louis, Missouri 63110, USA

Chondrocytes in the fetal skull and visceral cartilage are considered to be of neural crest origin[1] while those found elsewhere in the body are thought to be derived from mesoderm[2,3] (mesodermal chondrocytes). Chondrocytes of pelvic rudiments from chick embryos are the only cells known to respond to nerve growth factor that are not of neuroectodermal origin[4]. In addition, embryonic spinal cord[5] and neural retina[6] of chickens synthesize type II collagen[5,6], originally thought to be confined to cartilage. Here we report the presence of the S-100 protein (S-100) in chondrocytes of skull, vertebrae, ribs, sternum, larynx and long bones of the human fetus, and larynx and xiphoid process of the human adult. Mesodermal chondrocytes are the only cells which contain S-100 and yet are not considered to be of neuroectodermal origin, thus our results indicate that these chondrocytes may be developmentally closer to neuroectoderm than traditionally thought.

S-100, an acidic protein which has been isolated from the central nervous system (CNS) of mammals, has a molecular weight (M_r) of 21,000–24,000 (refs 7–9) and exists in both membrane-bound and soluble forms[10]. It has been shown to increase activity of RNA polymerase in nuclei isolated from brains of immature chickens[11]. S-100 facilitates passage of γ-aminobutyric acid across nerve-cell membranes[12] and undergoes orthodromic axonal transport[13]. In the CNS the concentration of S-100 is low at birth, increasing with age[7,14].

S-100 has been detected by immunological methods in all vertebrates examined[7]. In the CNS, it is located primarily within astrocytes and oligodendrocytes[15–17]. Some investigators have also demonstrated S-100 in CNS neurones[18–20] and in isolated synaptosomes[10]. Outside the CNS, S-100 has so far been demonstrated only in Schwann cells of peripheral nerve and in satellite cells of dorsal root and autonomic ganglia[21].

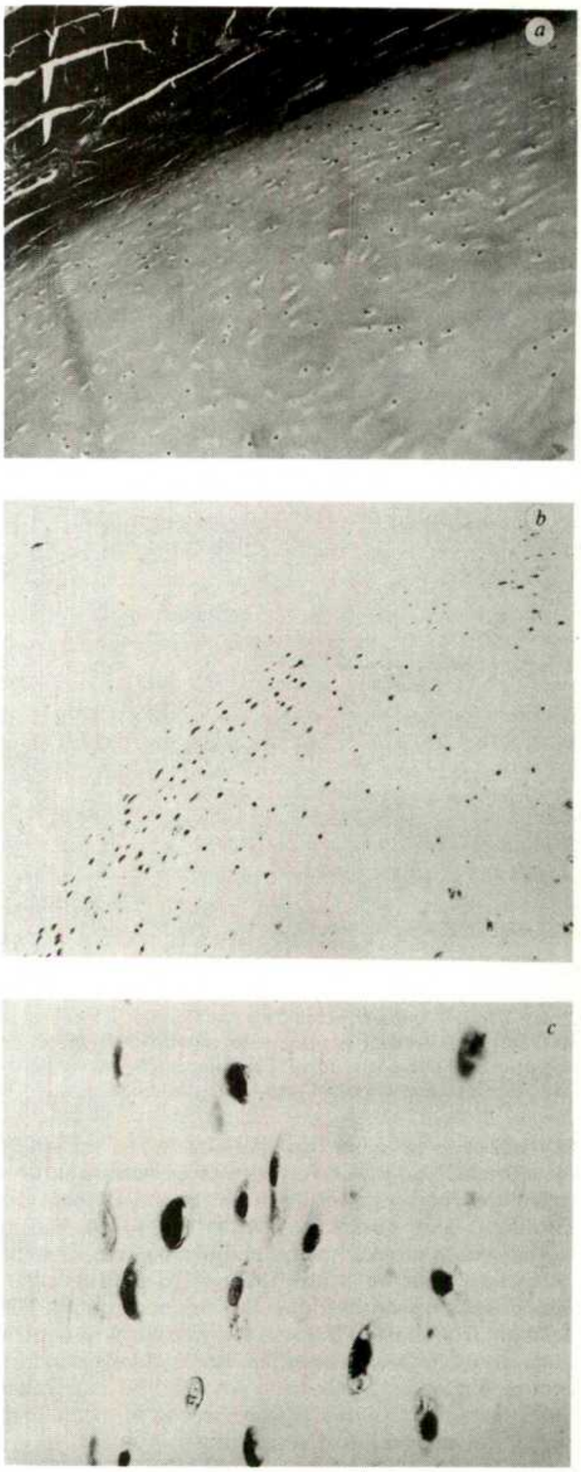

Fig. 1 Serial paraffin sections from the xiphoid process of human adult: *a*, haematoxylin and eosin stain (×90); *b*, immunoperoxidase reaction for S-100 protein, without counterstain (×90). Reaction product is present only within chondrocytes; the extracellular matrix of the cartilage and the surrounding fibrous connective tissue are unstained. *c*, Same section as *b* (×500).

While looking for S-100 in the fetal nervous system we discovered that the protein is present in chondrocytes of the vertebral column and decided to determine its distribution using anti-S-100 antiserum and the peroxidase–antiperoxidase method described elsewhere[22]. Rabbit anti-S-100 antiserum was raised by five or more intradermal injections of bovine

0028–0836/82/010063—02$01.00

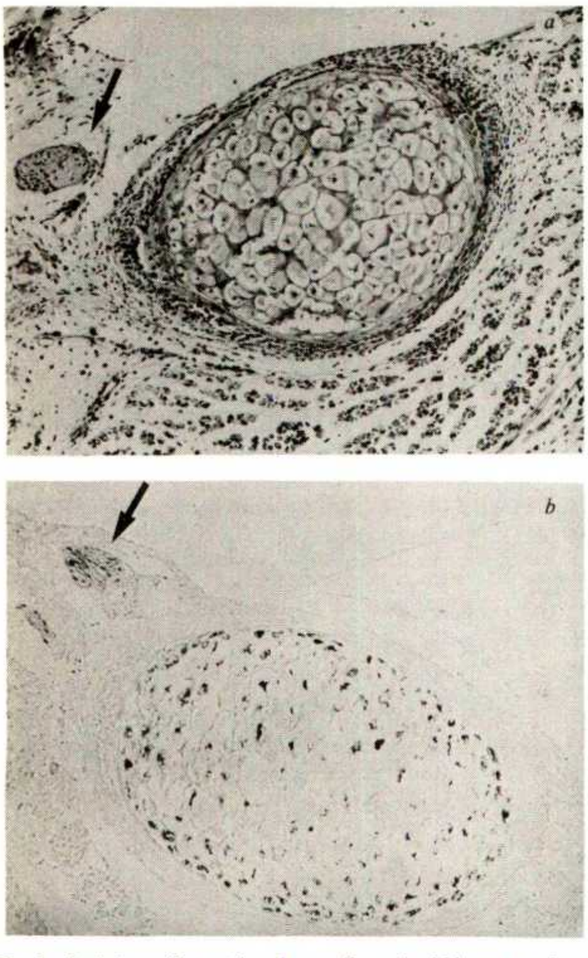

Fig. 2 Serial paraffin sections from a 7-week-old human embryo. *a*, Haematoxylin–eosin stain of a rib and adjacent intercostal nerve (arrow), ×100. *b*, Immunoperoxidase reaction for S-100 protein, ×100. Reaction product is present in chondrocytes of rib and Schwann cells of intercostal nerve. The adjacent fibrous connective tissue and skeletal muscle are unstained.

S-100 (isolated as described previously[7,23]), mixed with complete Freund's adjuvant. As control sera we used anti-S-100 antiserum absorbed with S-100 until it no longer reacted with human brain, and serum from a rabbit which had been immunized with complete Freund's adjuvant alone. The anti-S-100 antiserum and the control sera were used at dilutions containing the same concentration of immunoglobulins. Tissues studied were from human fetuses of various ages and included cranium, larynx, trachea, vertebrae, ribs and lower and upper extremities. Xiphoid processes and laryngeal cartilage of adults were also examined. All tissues were fixed in formalin, embedded in paraffin and cut into 6-μm sections.

Chrondrocytes in all tissues examined were stained with anti-S-100 antiserum. Staining was both cytoplasmic and nuclear; the extracellular matrix was unstained. Control sera did not stain any of the tissues (Figs 1, 2).

Chondrocytes which form the fetal skull as well as the visceral cartilage are said to be of neural crest origin[1] and those found elsewhere are considered to be derived from mesoderm[2,3]. Nevertheless, it is accepted that tissues of neuroectodermal origin can exert a considerable influence on differentiation of mesodermal chondrocytes[3]. Extirpation of the neural tube from chick embryos inhibits formation of axial cartilage, and grafting of spinal cord with or without notochord and neural crest into any region of the somite of tail-bud embryos results in formation of a complete secondary vertebral column[2]. The standard interpretation of these phenomena has been that the spinal cord induces formation of cartilage in the somites[3].

Type II collagen was originally thought to be unique to cartilage but recently it has been demonstrated that neural retina[6] and probably spinal cord[5] of chick embryos also produce type II collagen. In addition, nerve growth factor inhibits chondromucoprotein synthesis by cartilage of pelvic rudiments from chick embryos[4]. Mesodermal chondrocytes are the only cells known to respond to nerve growth factor but not thought to be of neuroectodermal origin.

We have shown that S-100 is present in both mesodermal and neural crest chondrocytes of man. The presence of S-100 in chondrocytes of skull, larynx and trachea is perhaps not unexpected, but the fact that we have found S-100 in chondrocytes of vertebrae, ribs, xiphoid processes and extremities suggests that mesodermal chondrocytes may be developmentally closer to neuroectoderm than was previously believed.

Note added in proof: The S-100 protein has recently also been identified in melanocytes and Langerhans cells of normal human skin by D. Cocchia, F. Michetti and R. Donato (*Nature* **294,** 85–87 (1981)).

A very small porcine virus with circular single-stranded DNA

I. Tischer, H. Gelderblom, W. Vettermann & M. A. Koch

Robert Koch-Institute of the Federal Health Office, Nordufer 20,
1000 Berlin 65, FRG

It was reported previously that cultures of the porcine PK-15 cell line (ATCC-CCL31) were chronically infected with a small virus, supposedly containing RNA[1]. No gross cytopathic effect was seen in these cultures. During the search for an *in vitro* model of persistent virus infections the agent was studied in more detail. These studies showed the virus to have a diameter of 17 nm, and to contain a covalently closed circular single-stranded DNA with a molecular weight of 0.58×10^6 and a main capsid polypeptide with a molecular weight of 36,000. Of the animals tested, only pigs were found to have antibodies. On the basis of these properties the virus appears to be a member of a family of animal viruses so far not encountered. We have named the virus porcine circovirus (PCV).

The virus was obtained from PK-15 cells. It can be propagated in selected PK-15 clones which are free of porcine parvovirus, porcine papovavirus, mycoplasmas and of PCV. Virus was concentrated by ultracentrifugation of Freon-treated cells and supernatants and then purified by two cycles of CsCl-gradient centrifugation. Sucrose gradient centrifugation yielded a sedimentation coefficient for the virion of 52S. On isopycnic centrifugation in CsCl virus particles banded exclusively at a density of 1.37 g cm^{-3}. Electron micrographs (Fig. 1) confirmed that the

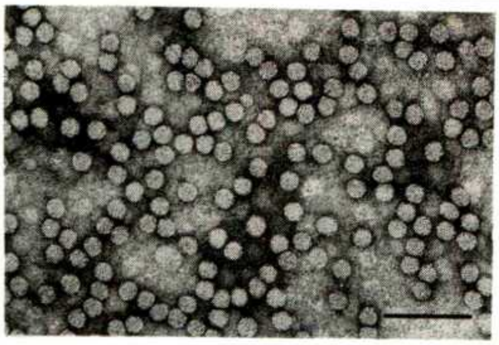

Fig. 1 Electron micrograph of purified PCV particles negatively stained with 1% aqueous uranyl acetate. Scale bar, 100 nm.

virus is an isometric particle with a diameter of 17 ± 1.3 nm. No stain-filled particles were observed.

Purified ^{3}H-leucine-labelled virus was disrupted at 100 °C for 1 min with SDS (1%) and mercaptoethanol and the protein moiety was analysed by polyacrylamide gel electrophoresis[2]. Only a single band containing radioactivity was found. Its position corresponded to that of a polypeptide of molecular weight 36,000 ± 2,300, using bovine serum albumin, ovalbumin and chymotrypsinogen as references.

For isolation and characterization of the nucleic acid, [*Me*-^{3}H]thymidine-labelled virus was lysed with SDS (0.5%) and sodium *N*-lauroyl sarcosinate (1%) for 15 min at room temperature, followed by a digestion with proteinase K (500 μg ml^{-1}) for 4 h at 37 °C. Nucleic acid was purified by centrifugation in a neutral sucrose gradient (5–20% wt/wt; rotor SW 40; 33,000 r.p.m.: 7.5 h; 20 °C), and by precipitation with two parts of ice cold ethanol containing 0.4 M lithium chloride. The pellet was washed with 75% ethanol and then resuspended in 0.1 × SSC. The incorporation of ^{3}H via [*Me*-^{3}H]thymidine, the buoyant densities and the alkali stability demonstrated that the nucleic acid of PCV is DNA. The buoyant densities were found to be 1.718 g cm^{-3} in CsCl using adeno 2 ^{14}C-DNA (1.715 g cm^{-3}) and DNA from *Micrococcus lysodeikticus* (1.731 g cm^{-3}) as markers, and in Cs_2SO_4 to be 1.45 g cm^{-3}. Purified tritium-labelled PCV DNA was kept in 0.3 M NaOH for 20 h at room temperature[3]. The radioactivity in trichloroacetic acid precipitates of treated and untreated nucleic acids was then assayed. While an untreated control yielded of the order of 5,500 c.p.m. the treated sample contained 5,750 c.p.m. The efficacy of this treatment on RNA was tested using 16S and 23S ribosomal RNA.

In transfection experiments[4] native PCV DNA purified as above was shown to be infective (~0.04 μg PCV DNA per 1.5 × 10^6 cells). This infectivity was abolished completely by DNase 1—that is, using DNase-treated PCV DNA for transfection, cells producing virus, as revealed by staining with fluorescein-labelled specific antibodies, were not detectable even after two passages of the cells. In control experiments with untreated PCV DNA, more than 1,000 specifically stained cells per 1.5-cm diameter coverslips with about 2.5 × 10^5 cells were seen.

The sedimentation behaviour of native PCV DNA and of heat- or alkali-treated PCV DNA in neutral sucrose gradients as well as in alkaline gradients (Fig. 2) revealed that the DNA is single stranded[5]. The degradation of PCV DNA by the single-strand-specific nuclease S_1 confirmed this conclusion (Fig. 3). The sedimentation coefficient of PCV DNA determined in 1 M NaCl at *p*H 7.2 was 12.7S, and about 9S at *p*H 12.7. In 1.5% agarose gels the PCV DNA migrated about 2.3 times further than ΦX174 virion DNA.

When PCV DNA was examined by electron microscopy more than 85% of the molecules seen were circular (Fig. 4). To determine the size of the circular DNA, contour length measurements were performed using ΦX174-am-3 virion DNA[6] as an internal marker. From the data for ΦX174

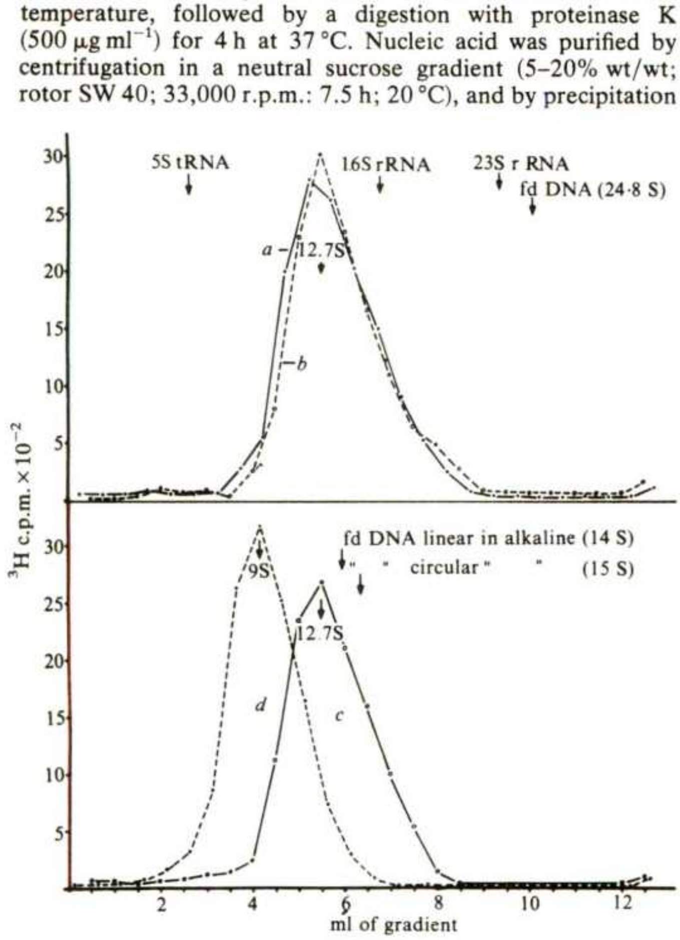

Fig. 2 Sedimentation profiles of [*Me*-^{3}H]thymidine-labelled native, heated and alkali treated PCV DNA in sucrose gradients (5–20% wt/wt). *a*, Native DNA; *b*, heated DNA (10 min; 100 °C) *c*, alkali treated (0.1 M NaOH; 5 min; 22 °C) and subsequently neutralized (with 0.1 M HCl) DNA in neutral gradients (1 M NaCl; 0.01 M Tris; 0.001 M EDTA; *p*H 7.2); *d*, alkali-treated DNA in an alkaline gradient (0.9 M NaCl; 0.1 M NaOH; 0.001 M EDTA; *p*H 12.7). Beckman rotor SW 40; 33,000 r.p.m.; 7.5 h; 20 °C. The sedimentation coefficients of PCV DNA were determined on the basis of the sedimentation of the markers (RNA) in the neutral gradient. For comparison virion fd-DNA was included.

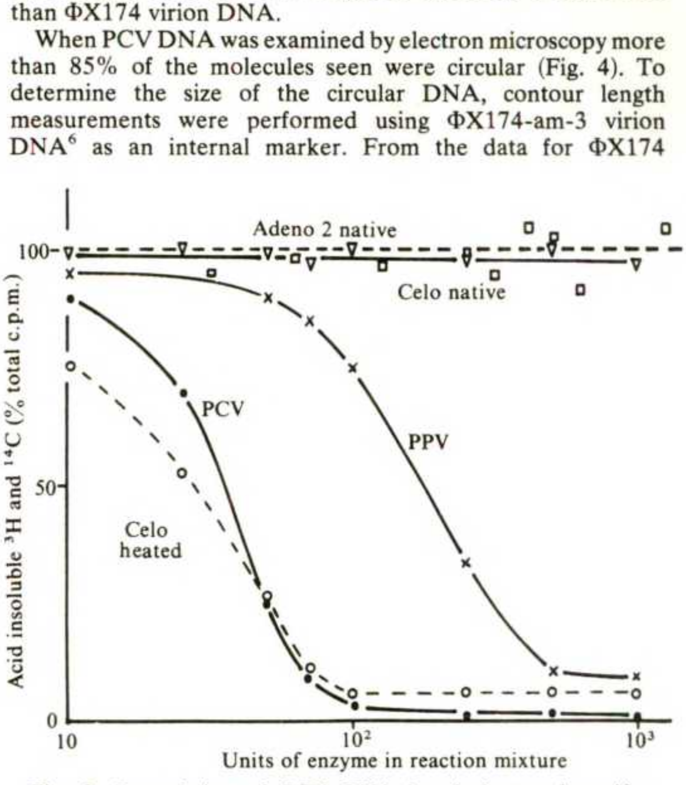

Fig. 3 Degradation of PCV DNA by single-strand-specific nuclease S_1. PCV DNA was treated with nuclease S_1 (buffer: 0.1 M Na-acetate; 0.1 mM $ZnSO_4$; *p*H 4.5) in parallel with the double-stranded ^{14}C-adeno 2-DNA and ^{3}H-Celo-DNA as well as with the single-stranded ^{3}H-DNA from porcine parvovirus (PPV) and denatured (95 °C, 10 min) ^{3}H-Celo DNA. DNA was incubated with nuclease S_1 for 30 min at 37 °C and DNA was precipitated with trichloroacetic acid at a final concentration of 5% in the presence of 100 μg carrier RNA. Degradation is expressed as the relative loss of acid-precipitable radioactivity by increasing amounts of enzyme.

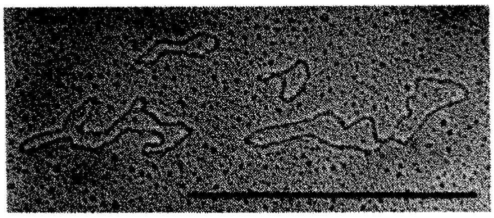

Fig. 4 Electron micrograph of PCV DNA (top) and ΦX174 virion DNA (bottom). A mixture of both species was spread from a hyperphase (carbonate buffer *p*H 10, 0.01% cytochrome *c*, 40% formamide) at room temperature. The specimen was rotary shadowed with Pt/Pd. Scale bar, 1 μm.

($n = 198$, 1.94 ± 0.12 μm) and for PCV ($n = 212$, 0.633 ± 0.05 μm) a genome size of 1.76 kilobases, corresponding to a molecular weight of 0.58×10^6, was calculated for PCV.

The sedimentation behaviour described above (Fig. 2) shows that the configuration of the molecule is unaffected by denaturing conditions, that is, after renaturation molecules of multiple unit length were never detected. This indicates that PCV DNA is a covalently closed circular molecule rather than a closed circle due to self-complementing cohesive ends. This interpretation is supported by the fact that no linearization of PCV DNA was detected when DNA was spread under heat denaturation. As internal controls *Hin*dII, *Hin*dIII restriction fragments of fd-DNA carrying the transposon Tn*5* (ref. 7) were included. These restriction fragments consist of DNA molecules which are circular due to self-complementary ends of 190 and 340 bases respectively which readily opened in the conditions used.

Purified virus was used to raise specific antibodies in rabbits. Such antibodies aggregated PCV, neutralized infectivity and, using indirect immunofluorescence, detected virus producing cells. It was found that in chronically infected cultures only a small, but varying proportion of cells expressed virus antigens. PCV antisera did not inhibit agglutination of human red blood cells by porcine parvovirus. Attempts to demonstrate agglutination by PCV or RBC from man, rhesus monkey, pig, rabbit, guinea pig, mouse and chicken were unsuccessful.

Most probably the agent has its origin in pigs. A serological survey showed that 20 out of 22 randomly collected pig sera contained specific antibodies. Sera from rabbits, mice, calves and man, including sera from laboratory staff working with the agent, were negative. The physicochemical properties of this agent set it apart from all known animal viruses[8]. Similarities exist only with several plant pathogens comprising the group of geminiviruses[9,10].

We thank Renate Rasch, Doris Peters, S. Pociuli, H. Reupke and D. Elsen for technical assistance. Helpful suggestions were made by Professor H. Ludwig, Professor H. Köhler, and Drs Giovanna Morelli, G. Pauli, E. Werner and especially by Professor H. Schaller who also donated the fd derivative fd Km-30 and its restriction fragments.

A monoclonal antibody against human T suppressor lymphocytes binds specifically to the surface of cultured oligodendrocytes

Joel Oger

INSERM U-49, 35043 Rennes, France

Sara Szuchet, Jack Antel & Barry G. W. Arnason

Department of Neurology and the Brain Research Institute,
University of Chicago, Chicago, Illinois 60637, USA

The cardinal pathological feature of multiple sclerosis (MS) is the presence within brain and spinal cord of regions called plaques, from which myelin has been lost[1]. It has been proposed that autoimmunity may be involved in MS and that oligodendrocytes, the cells responsible for the formation and maintenance of central nervous system myelin, may provide a target for immune attack in this disease. The fact that oligodendrocytes are reduced in number in MS plaques[2] is consistent with this hypothesis. MS is characterized by attacks and remissions. During attacks, a subset of T lymphocytes, known as T suppressor cells, is depleted from the circulation[3–5]. The reason for this depletion is unknown, but the suppressor cells could be destroyed, sequestered, for example in brain, or modulated so that they are no longer detectable by the assays which enumerate them or which measure their functional capacities. Were suppressor cells and oligodendrocytes to share a determinant relevant to MS, both cell types could be targets for immune-mediated killing by the same autoimmune response. Recently, monoclonal antibodies which recognize human monocytes, T lymphocytes and T-cell subsets have become available. We have tested cultured ovine oligodendrocytes with a battery of monoclonal antibodies directed against human lymphocyte and monocyte antigens, seeking evidence for shared determinants, and present here data suggesting that shared determinants exist.

All antibody clones were produced by hybridization of spleen cells from mice sensitized to human T lymphocytes with P3 mouse myeloma. Antibodies were generated by intraperitoneal passage of cloned hybrid cells in mice[6]. Oligodendrocytes were isolated from the white matter of 4–6-month-old lambs as described previously[7,8]. Trypsin was used in the isolation procedure. Cells were plated on glass chamber slides and maintained in culture for up to 40 days (for details see Fig. 1 legend); medium was changed twice weekly. Cultured cells were identified as oligodendrocytes by ultrastructural, biochemical and immunological criteria[9]. Cultured oligodendrocytes were washed free of medium and pre-reacted with normal sheep serum (NSS) as a source of excess sheep IgG. All monoclonal antibodies were screened at a concentration of 5 μg IgG per ml, the cultures were washed, and binding of the monoclonal antibodies was assessed by adding goat anti-mouse IgG labelled with fluorescein isothiocyanate (FITC).

As shown in Fig. 1, cultured oligodendrocytes pretreated with 1:500 NSS, exposed to OKT8 and then to 1:10 goat anti-mouse IgG–FITC, gave distinct membrane-bound fluorescence with scattered irregular dots outlining the cell cytoplasm and processes. This pattern of fluorescence resembles that seen when human suppressor lymphocytes are reacted with OKT8. A similar fluorescence pattern was obtained with OKT3 and OKM1. In contrast, OKT4, OKT5, OKT6, OKT10 or OKI1 showed no fluorescence. Control cultures incubated with goat anti-mouse IgG–FITC alone were negative, as was ascitic fluid (produced by injecting P3 mouse myeloma cells into mice), even at 2 mg ml^{-1} IgG. In dilution experiments, using the same 1:10 dilution of goat anti-mouse FITC, OKT3 became negative at concentrations below 2.5 μg ml^{-1} IgG, but OKT8 and OKM1 remained positive at 1.25 μg ml^{-1} IgG. Table 1 gives the IgG subclasses of the monoclonal antibodies used, their specificities for human cell types, and summarizes the data on membrane-bound fluorescence.

As immunoglobulins can bind nonspecifically to Fc receptors on cells or specifically through their Fab portion, it was possible that monoclonal antibody binding was occurring through the Fc

* Commercially available from Ortho Laboratories at 25 μg ml^{-1} of mouse IgG. † Commercially available from Ortho Laboratories at 50 μg ml^{-1} of mouse IgG. ‡ Ascitic fluid gift of Dr P. C. Kung obtained at 2 mg ml^{-1} of mouse IgG.

region, particularly as oligodendrocytes have been shown to bear Fc receptors[10,11]. Sheep red blood cells (SRBC) coated with mouse anti-SRBC were shown to form rosettes with our oligodendrocyte population. This Fc rosetting was totally inhibited by preincubating oligodendrocytes with a 1:10 dilution of NSS. Human lymphocytes to which the mouse monoclonal antibody OKT8 had been bound specifically also formed rosettes with oligodendrocytes (Fig. 2). This Fc receptor binding was also blocked by preincubating the oligodendrocytes with a 1:10 dilution of NSS (Fig. 2). Direct binding of OKT3, OKT8 and OKM1 to oligodendrocytes was therefore re-evaluated following a preincubation of the oligodendrocytes in 1:10 NSS. OKT3 and OKM1 binding was no longer seen, indicating that their binding might have occurred through Fc. Although Fc receptor binding is known to depend on IgG subclass when IgG and Fc receptors are from the same species[12], we found no correlation between mouse IgG subclass and monoclonal antibody binding to ovine oligodendrocyte Fc receptor. This might be attributable to species differences, to the presence of aggregates in some of the OKT or to variability in the structure of the Fc regions of the monoclonal antibodies.

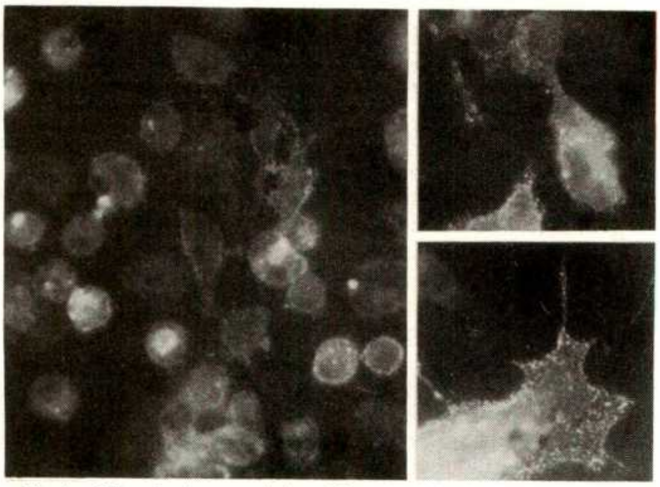

Fig. 1 Oligodendrocytes isolated from lamb brain (as described in ref. 8) were cultured (in multiple-well glass slides) in Dulbecco's modified minimum essential medium (with 20% horse serum added) at 37 °C in humidified air containing 5% CO_2. After 2–3 weeks in culture, the slides were washed three times with Ca^{2+}–Mg^{2+}-free Hanks' balanced salt solution containing 1% bovine serum albumin, *p*H 7.4 (HBSS + 1% BSA). They were incubated for 15 min with a 1:500 dilution of heat-inactivated normal sheep serum in HBSS + 1% BSA. The preincubation solution was then aspirated off and mixed with the monoclonal antibody OKT8 (Ortho) up to a final concentration of 5 μg ml^{-1} of mouse IgG. The mixture was added back to the cells and allowed to react for 30 min at 0 °C. After three washes with HBSS + 1% BSA, a 1:10 dilution of goat anti-mouse IgG–FITC was added for 30 min at 0 °C. The goat anti-mouse IgG–FITC (Cappel) was diluted with one part heat-inactivated normal goat serum and eight parts HBSS + 1% BSA. Slides were then washed four times, fixed with 4% paraformaldehyde in HBSS at 0 °C, mounted and observed under a Leitz Ortholux II UV microscope. Pictures were taken with an Orthomat camera.

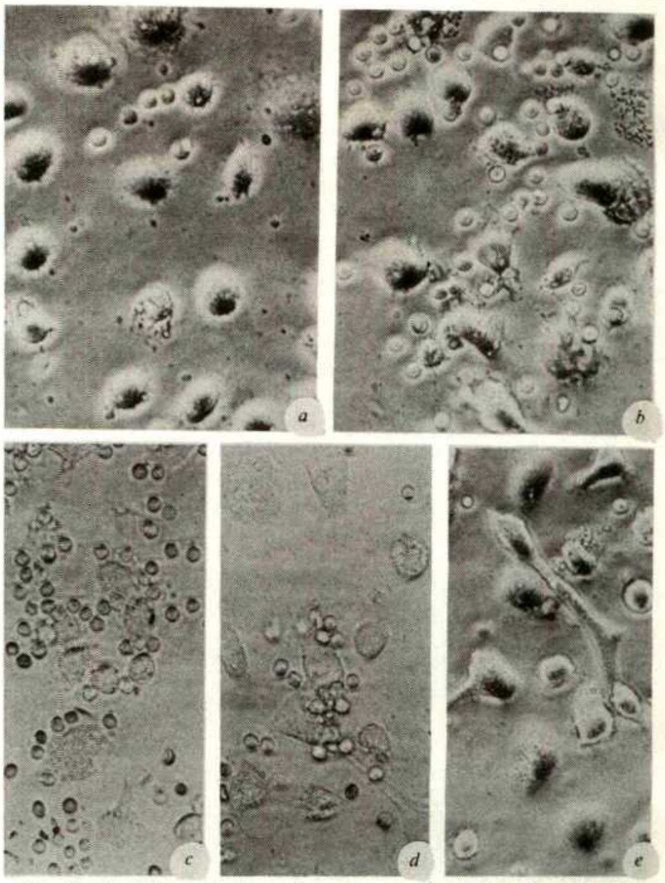

Fig. 2 Blocking effect of sheep serum on Fc binding of the monoclonal antibody OKT8. Human mononuclear cells were separated from peripheral blood by Ficoll–Hypaque flotation[13]. T lymphocytes were then isolated by the nylon wool technique[14]. After washing, T cells were incubated at 4 °C for 30 min with a 5 μg ml^{-1} solution of OKT8 in HBSS + 1% BSA and washed three times in the cold. 20% of the T lymphocytes were shown by immunofluorescence to have bound OKT8. T cells coated with OKT8 were then added to oligodendrocytes in culture. After centrifugation at 200*g* for 5 min, incubation for 30 min and gentle washing, cultures were observed for the presence of T cells bound to oligodendrocytes. In *a*, uncoated lymphocytes have been added and no binding is seen. In *b*, T cells precoated with OKT8 have been added to washed oligodendrocytes; the presence of free Fc receptor is shown by binding of the T cells to the oligodendrocytes. *c*, *d* Demonstrate reduced binding after preincubating oligodendrocytes with 1:500 (*c*) and 1:50 (*d*) NSS. *e* Shows that a 1:10 dilution of NSS in the preincubation step totally blocks binding to Fc receptors.

After preincubation with 1:10 NSS, OKT8 binding was still evident by immunofluorescence (Fig. 3), again in a pattern reminiscent of that seen when human suppressor T cells are reacted with OKT8. Ultracentrifugation of OKT8 at 100,000*g* for 1 h, to remove aggregated IgG, did not affect its binding to oligodendrocytes.

Galactocerebroside is an accepted marker for oligodendrocytes. Double labelling experiments were done using, in a first step, a mixture of OKT8 and rabbit anti-galactocerebroside antiserum and in the second step, goat anti-mouse IgG (FITC labelled) mixed with goat anti-rabbit IgG (rhodamine labelled). Using three-week-old cultures, 75% of cells labelled for galactocerebroside, 86% for the T8 antigen and 68% showed double labelling.

Freshly isolated ovine oligodendrocytes studied in suspension did not exhibit fluorescence with any of the antibodies tested.

Thus, the OKT8 reactive determinant, as well as the Fc binding site, seems to be lost during the isolation procedure and regenerated in culture. Failure of freshly prepared cells to bind could be a consequence of the trypsinization step used during isolation. Indeed, when 0.3 mg ml^{-1} of trypsin was added for 45 min at 37 °C to human mononuclear cells in suspension or to ovine oligodendrocytes which had been maintained in culture, both lost their capacity to bind OKT8, OKT3 and OKM1. Serial experiments performed using OKT8 showed that antibody binding was first evident after 3 days in culture and was invariably present thereafter up to 40 days in culture, the last time point tested. Per cent positive cells varied between cultures but binding was always present in more than 50% of the cells.

We attempted to stain non-trypsinized sheep hepatocytes in suspension and cultured sheep fibroblasts using the same antibodies; neither cell type was positive with any monoclonal antibody. These results indicate that cross-reactivity of the monoclonal antibodies is at least relatively restricted to oligodendrocytes and does not reflect reactivity with globally distributed ovine antigens. Interestingly, sheep splenocytes in suspension did not stain with any of the monoclonal antibodies. It would be of paramount interest to develop methods for maintaining human oligodendrocytes in culture and to test them for reactivity against OKT3, OKM1 and OKT8.

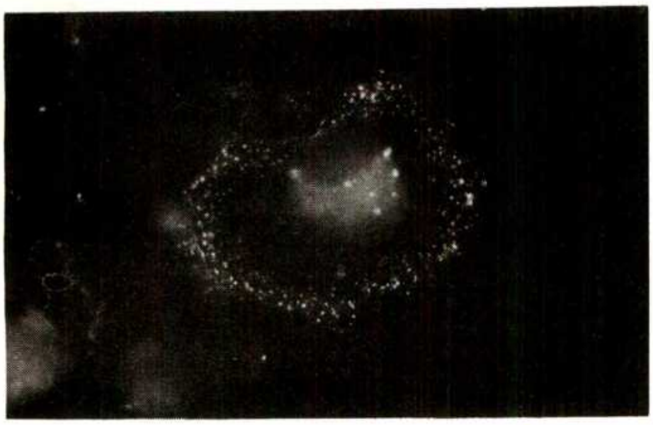

Fig. 3 Immunofluorescence pattern of oligodendrocytes stained with OKT8 in conditions described in Fig. 1 legend, except that a 1 : 10 dilution of normal sheep serum (shown to block Fc receptors) was used in the preincubation step.

If determinants are shared by suppressor lymphocytes and oligodendrocytes, as the present data suggest, this could explain why both suppressor cells and oligodendrocytes disappear in multiple sclerosis. The nature of the putative multiple sclerosis-relevant antigen in brain may even be approachable through study of circulating lymphocytes.

This work was supported by National Multiple Sclerosis Society grants MS:RG 1223-B-3 and MS:RG 1130-C-16. Monoclonal antibodies (in mouse ascites fluid) were purchased from Ortho Laboratories (OKT3, OKT4, OKT6 and OKT8) or were provided by Dr P. C. Kung (OKM1, OKT5, OKT10 and OKI1). Anti-galacto cerebroside antiserum was a gift from Dr R. Lisak.

T-cell mitogens cause early changes in cytoplasmic free Ca^{2+} and membrane potential in lymphocytes

One of the best models for studying the control of mammalian cell growth and proliferation is the response of lymphocytes to mitogenic agents[1–4], which stimulate growth, DNA synthesis and division. How mitogens work remains obscure, although it has been hypothesized that they increase cytoplasmic free calcium, $[Ca^{2+}]_i$, as a trigger for the cascade of intracellular processes necessary for proliferation[3–6]. However, lymphocyte $[Ca^{2+}]_i$ has not previously been measurable. A new technique[7] for loading a novel Ca^{2+}-specific indicator[8] into the cytoplasm of intact small cells has now made possible the first direct measurements of $[Ca^{2+}]_i$ in mouse thymocytes and pig node lymphocytes. We show here that lectins known to stimulate T cells raise average $[Ca^{2+}]_i$ approximately twofold within a few minutes. Deprivation of external Ca^{2+} or elevation of cyclic AMP, conditions known to inhibit mitogenesis, prevented the $[Ca^{2+}]_i$ response. Rises in $[Ca^{2+}]_i$ were accompanied by hyperpolarization of the membrane potential, apparently due to a Ca^{2+}-activated K^+ conductance. The co-carcinogen 12-*O*-tetradecanoylphorbol-13-acetate (TPA) seems to stimulate cell functions normally activated by Ca^{2+}.

$[Ca^{2+}]_i$ was measured with a fluorescent indicator (structure 3b of ref. 8, now called 'quin2') which shows a fivefold fluorescence enhancement on binding Ca^{2+}. Quin2 has a 1:1 stoichiometry of Ca^{2+} binding, with an apparent dissociation constant[9] of 115 nM in the presence of 130 mM K^+, 20 mM Na^+, 1 mM free Mg^{2+}, at *p*H 7.05 and 37 °C, conditions chosen to mimic lymphocyte cytoplasm (refs 10, 11 and T.P., T.J.R. and R.Y.T., in preparation). The indicator was trapped inside the cells by incubating them with its membrane-permeant intracellularly hydrolysable acetoxymethyl ester[7]. Available tests suggest that the quin2 is free in the cytoplasm, not significantly contained in organelles such as mitochondria, and neither excluded from nor accumulated in the nucleus, so that its signals can be taken to measure cytoplasmic free calcium[9]. The signals are calibrated by releasing the indicator from the cells with digitonin or Triton X-100 at the end of the experiment and recording the fluorescence at 0% and 100% Ca saturation, that is, <1 nM and 1 mM $[Ca^{2+}]$. From these fluorescence levels, F_{min} and F_{max}, the $[Ca^{2+}]_i$ corresponding to fluorescences F from trapped intracellular dye, are calculated by the equation

$$[Ca^{2+}] = (115\ nM)(F - F_{min})/(F_{max} - F)$$

Parallel measurements of lymphocyte membrane potential (V_m) were made with a potential-sensitive oxonol dye as previously described[12].

Figure 1 shows fluorescence signals from quin2-loaded lymphocytes. The indicated resting $[Ca^{2+}]_i$ had a mean ± s.e. of 123 ± 6 nM ($n = 27$). These levels are consistent with those measured in other cell types[13] and argue against any gross toxicity. Further evidence against toxicity was that (1) loaded cells maintained high (<90%) eosin exclusion; (2) ATP levels[9] remained within 30% of normal with up to 3mM intracellular quin2; (3) capping of surface ligands was unaffected by quin2 (ref. 14); (4) membrane potential responses of quin2-loaded mouse thymocytes were similar to those of normal cells

(compare Figs 2 and 3*b*); and (5) thymocytes and spleen cells loaded with quin2 and then treated with concanavalin A (Con A) at normal optimal doses can undergo mitogenic transformation as assessed by thymidine uptake (T. R. Hesketh, personal communication). All our results pertain to cells washed free from ester hydrolysis products after the loading period; leaving the hydrolysis by-products in the suspension may have long-term deleterious effects.

Although quin2 is a Ca^{2+} chelator, increasing its loading does not affect steady-state $[Ca^{2+}]_i$. Atomic absorption measurement of total Ca shows that during loading, the cells take up sufficient Ca from the medium approximately to half-saturate the trapped quin2 and keep $[Ca^{2+}]_i$ near 120 nM. Loading in Ca^{2+}-free medium does reduce $[Ca^{2+}]_i$ to as low as 16 nM (ref. 9).

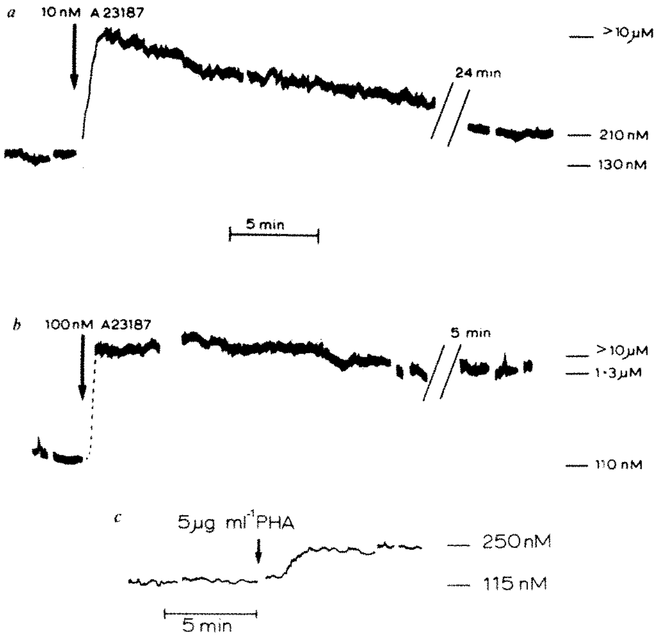

Fig. 1 Resting $[Ca^{2+}]_i$ levels and responses to A23187 and PHA. *a*, *b*, Lymphocytes from the mesenteric nodes of pigs were prepared as previously described[36]. Quin2 acetoxymethyl ester (50 µM) was added to a cell suspension containing about 10^8 cells per ml and incubated for 20 min. The suspension was then diluted 10-fold and incubated for a further 40–60 min. The resulting quin2 loading was typically 2 mmol per litre of cells; higher or lower loadings could be achieved by altering the ester concentration. After loading, the cells were centrifuged at 1,000*g* for 3–4 min and resuspended in fresh RPMI–1640 at $\sim 10^7$ per ml and kept at room temperature. Cells usually lost <5% of their dye per hour. For measurement of fluorescence, 1–2 ml of this stock suspension was centrifuged for a few seconds at 14,000*g* and the cells resuspended in 2 ml of a physiological saline and transferred to the cuvette, the whole resuspension procedure taking about 1 min. Unless otherwise specified, the physiological saline consisted of (mM): NaCl, 145; KCl, 5; Na_2HPO_4, 1; $CaCl_2$, 1; $MgSO_4$, 0.5; glucose, 5; Na HEPES, 10; *p*H 7.40 at 37 °C. This simplified saline was routinely used instead of RPMI–1640 because the latter contains many absorbing and fluorescing substances; however, qualitatively similar $[Ca^{2+}]_i$ signals (see *c*) could be obtained in the full culture medium. Typical measurement conditions, with 2 mM quin2 content in $0.5-1\times10^6$ cells per ml, are equivalent to about 1–2 µmol dye per litre of suspension. Quin2 fluorescences were recorded with Perkin-Elmer MPF-44 spectrofluorimeters in cuvettes thermostatted to 37 °C. Excitation and emission wavelengths were 339 and 492 nm with 4 and 10 nm bandwidths. 10 or 100 nM A23187 added from dimethyl sulphoxide (DMSO) stock solutions as indicated. Final DMSO concentrations were 0.1% (v/v); control experiments showed no effect of DMSO up to 1%. *c*, PHA (Sigma) was added as indicated to mouse thymocytes teased from thymus glands of 5–8-week-old BALB/c mice and loaded with 2 mM quin2 content as in *a*, *b*. This experiment was done in RPMI–1640 medium containing 1 mM free Ca^{2+} and 0.2 mM Ca^{2+}-EGTA. Although PHA is less effective at stimulating thymidine uptake in thymocytes than in mature T cells, it does induce the early metabolic changes characteristic of mitogenesis[37,38]. In this and Figs 2 and 3, fluorescence was calibrated in terms of $[Ca^{2+}]_i$ as described in the text from F_{max} and F_{min} determined after quin2 release by 50 µM digitonin or 0.02% (v/v) Triton X-100. Cells not loaded with quin2 gave no fluorescence responses to ionophores or lectins. Gaps in the trace denote additions to or stirring of the suspension. The synthesis of quin2 is described in ref. 8. Quin2/AM was prepared from quin2 by the general procedure of ref. 7. Some experiments used batches of quin2/AM chromatographically purified and crystallized by Dr G. A. Smith, but with no difference in results from less exhaustively purified material.

Two different mitogenic calcium ionophores, A23187 (ref. 15) and ionomycin[16], each proved very potent in nanomolar concentrations at raising $[Ca^{2+}]_i$. Fig. 1*a* shows that 10 nM A23187, a submitogenic dose, increased $[Ca^{2+}]_i$ to a peak of ≥1 µM, from which it gradually decayed back nearly to resting level during 1 h. The decay may be due to slow disappearance of ionophore from solution[17], and could explain why 10 nM is a submitogenic dose[3]. A second addition of 10 nM A23187 can produce a renewed $[Ca^{2+}]_i$ rise. A single application of 100 nM A23187, the optimal mitogenic concentration[3], is sufficient to keep $[Ca^{2+}]_i$ above 1 µM for at least 40 min (Fig. 1*b*).

T lymphocytes can also be stimulated by the lectins phytohaemagglutinin (PHA) and Con A. At typically mitogenic doses both lectins give similar quin2 responses from thymocytes in 1 mM extracellular Ca^{2+}. A typical PHA response is shown in Fig. 1*c*. After a delay of 30–60 s, the fluorescence rises over 2–3 min by an amount corresponding to a 1.5- to 2.5-fold increase in average $[Ca^{2+}]_i$. Increasing the dye loading has no effect on the final apparent level of $[Ca^{2+}]_i$, which is 200–300 nM, but slows the response slightly. The elevation of $[Ca^{2+}]_i$ is maintained for at least tens of minutes with optimally mitogenic doses of Con A. In nominally Ca^{2+}-free media, Con A gives no increase in $[Ca^{2+}]_i$, which fits with the dependence[3,15,18,19] of lectin mitogenicity on extracellular Ca^{2+}. If Ca^{2+} is then added back to the Con A medium, $[Ca^{2+}]_i$ rises immediately. Agents which raise intracellular cyclic AMP levels are known to prevent or abort mitogenic stimulation[5,20,21]; the $[Ca^{2+}]_i$ response in thymocytes to Con A is antagonized by such agents, for example 100 µM theophylline, 10 mM Ro20/1724 (another phosphodiesterase inhibitor[21]), 0.25 µM dibutyryl cyclic AMP, or preincubation with 1 µg ml^{-1} cholera toxin. By contrast, no effects on $[Ca^{2+}]_i$ of millimolar exogenous cyclic GMP or its dibutyryl or 8-bromo derivatives have yet been detected.

These lectin-induced rises in average $[Ca^{2+}]_i$ may seem small. However, any influence of $[Ca^{2+}]_i$ on cell growth is probably exerted over several hours[3], giving time for a small activation to have a large cumulative effect. Moreover, not all the cells in these unfractionated populations are identically responsive to lectin[3,22–24]. If, say, half the cells remain at resting $[Ca^{2+}]_i$, at which level the quin2 is about 50% saturated with Ca^{2+}, the quin2 in the responsive cells would have to reach 80–90%

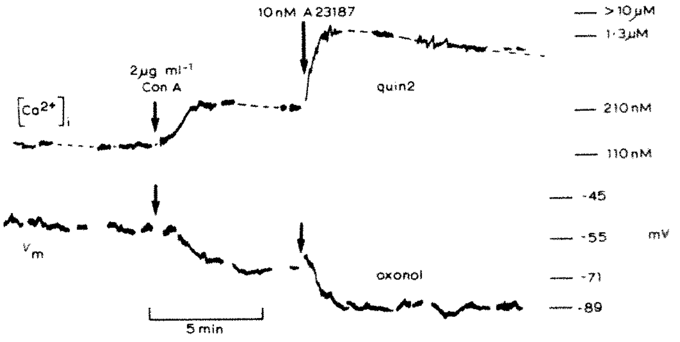

Fig. 2 Effect of Con A (Miles-Yeda, crystallized three times) on $[Ca^{2+}]_i$ and membrane potential, V_m. Mouse thymocytes containing 3 mM quin2 were in the standard physiological saline, to which was added 0.1 µM oxonol. Upper trace shows the quin2 signal, lower trace the oxonol fluorescence (excitation 540 nm, emission 580 nm) from another aliquot of the same batch of quin2-loaded cells. During each recording, the wavelengths were intermittently changed to verify that the other dye was responding normally, hence the large number of gaps in each trace. The V_m calibration was obtained after application of A23187 by adding KCl to raise external K^+ in steps and assuming that the increase in K^+ permselectivity was by then sufficient to bring V_m close to the K^+ equilibrium potential, E_K. The calibration marks relate oxonol fluorescence to E_K for each external K^+ concentration. The value of resting potential, −50 mV, estimated from oxonol fluorescence, is in reasonable agreement with independent assessments using the distribution of triphenylmethylphosphonium cation ($TPMP^+$) in other lymphocyte types[39,40]. However, the lectin-induced hyperpolarizations have not been reported previously. $TPMP^+$ equilibration takes 0.5–1 h and is thus not suitable for following early changes. Cyanine dyes[12] are unsuitable probes because they poison mitochondria, deplete lymphocyte ATP[41] and raise $[Ca^{2+}]_i$ to a point where lectins produce no further increase.

saturation ($[Ca^{2+}]_i = 450$–1,000 nM) to account for the observed average rise to 65–70% saturation. The quin2 response does not come primarily from the $[Ca^{2+}]_i$ of macrophages, since the response was not reduced by depletion of macrophages by adherence to glass, nor was any fluorescence response to Con A observed from macrophages obtained by peritoneal lavage and loaded with quin2.

We have found that lectin-induced $[Ca^{2+}]_i$ rises are sufficient to cause at least one immediate cell response: a negative shift of membrane potential. Figure 2 compares the $[Ca^{2+}]_i$ rise and the hyperpolarization in a single batch of quin2-loaded cells responding to mitogenic doses of Con A. The membrane potential as assessed by oxonol fluorescence changes from its resting level of approximately −50 mV to −70 mV with an initial delay and S-shaped time course similar to the $[Ca^{2+}]_i$ rise. A23187 produces an immediate further increase in $[Ca^{2+}]_i$ and hyperpolarization. The hyperpolarization is likely to be due to a K^+ conductance because it is associated with increased responsiveness of V_m to external $[K^+]$; also, of the main intracellular ions, only K^+ has an equilibrium potential[10,11,25] more negative than the resting potential. The hyperpolarization is also blocked by 0.5 mM quinine, an agent known to block Ca^{2+}-activated K^+ conductances[17]. Stimulation of electrogenic Na^+/K^+ pumping is probably not responsible because the hyperpolarization persists in the presence of 1 mM ouabain with only 1 mM external K^+. The hyperpolarization is a consequence of the $[Ca^{2+}]_i$ rise, not vice versa, as in Ca^{2+}-free solution Con A induces neither a rise in $[Ca^{2+}]_i$ nor hyperpolarization, but when external Ca^{2+} is restored, the $[Ca^{2+}]_i$ rise and V_m hyperpolarization develop in parallel. Conversely, imposed hyperpolarization or depolarization[26] do not affect the Con A-induced $[Ca^{2+}]_i$ rise. The similarity of the V_m responses between cells with and without quin2 (Figs 2 and 3*b*) argues that the indicator does not greatly perturb the $[Ca^{2+}]_i$ response to Con A.

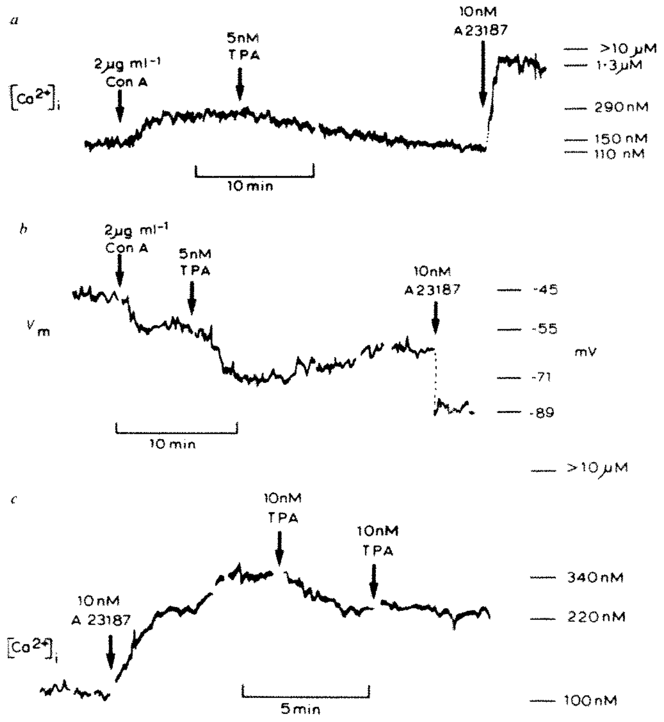

Fig. 3 Effects of TPA (Sigma). *a*, Mouse thymocytes containing 2 mM quin2. After elevation of $[Ca^{2+}]_i$ by Con A, $[Ca^{2+}]_i$ is reduced by 5 nM TPA to below the resting level. Finally 10 nM A23187 raises $[Ca^{2+}]_i$ to above 1 μM. *b*, Mouse thymocytes from the same preparation as *a* but not loaded with quin2. Signal from 0.1 μM oxonol. After a Con A hyperpolarization, 5 nM TPA causes a further, incompletely maintained hyperpolarization. V_m was calibrated as for Fig. 2. *c*, Pig lymphocytes loaded with 2.5 mM quin2. 10 nM TPA partially reversed the rise in $[Ca^{2+}]_i$ caused by A23187. A second addition of 10 nM TPA had no further effect. The smallness of the initial response to 10 nM A23187 may have been due to reduced potency of the particular stock solution used.

A counterexample to the correlations between known mitogenic potency and the ability to raise $[Ca^{2+}]_i$ was found in TPA, a weak mitogen by itself and a potent synergist with ionophores and lectins[16,27–30]. Ten nanomolar TPA gradually lowers resting $[Ca^{2+}]_i$, suppresses Con A-induced rises in $[Ca^{2+}]_i$ (Fig. 3*a*) and can even partly antagonize an ionophore response (Fig. 3*c*). These effects may be due to stimulated Ca^{2+} pumping. Yet TPA hyperpolarizes the cells by itself and enhances a Con A-induced hyperpolarization (Fig. 3*b*). The transience of the TPA hyperpolarization in Fig. 3*b* can be explained by the eventual fall in $[Ca^{2+}]_i$ counteracting the initial direct stimulation or increase in Ca^{2+} sensitivity of the K^+ conductance. All these actions of TPA are detectable in tens of seconds or minutes and are near-maximal at 10 nM, a concentration comparable with the reported dissociation constants for lymphocyte TPA-binding sites[31]. We suggest that TPA fairly directly stimulates a variety of normally $[Ca^{2+}]_i$-dependent processes, such as the Ca pump, K^+ conductance and events leading to mitogenesis. Analogous stimulations might explain many actions of TPA on other cell types[32–34], including the aggregation of platelets while lowering $[Ca^{2+}]_i$ (S. W. Smith, T.J.R. & R.Y.T., unpublished data). Interestingly, the high-affinity binding of phorbol diesters to cellular receptors is enhanced by $[Ca^{2+}]$ in the submicromolar range[35], suggesting that TPA binding may reciprocally increase the Ca^{2+} affinities of those receptors.

These results support the view that $[Ca^{2+}]_i$ is a primary messenger in lymphocyte mitogenesis, although we cannot say whether it is the only initial messenger without further studies such as analysis of lymphocyte heterogeneity and correlation of long-term $[Ca^{2+}]_i$ with mitogenesis. The surprising ability of the co-mitogen TPA to lower $[Ca^{2+}]_i$ can be rationalized by its stimulation of normally Ca^{2+}-dependent processes. Changes in $[Ca^{2+}]_i$ sensitivity of cellular processes, as well as modest sustained rises in $[Ca^{2+}]_i$, may be of more general significance in the control of normal and malignant cell proliferation.

This work was supported by SRC and CNR grants. T.P. held an EMBO Long-term Fellowship. We thank Dr G. A. Smith for samples of specially purified quin2 acetoxymethyl ester ('quin2/AM'), and Dr T. R. Hesketh for permission to cite unpublished results.

Lower fidelity of RecA protein catalysed homologous pairing with a superhelical substrate

Chanchal DasGupta & Charles M. Radding

Departments of Human Genetics and Molecular Biophysics and
Biochemistry, Yale University School of Medicine, New Haven,
Connecticut 06510, USA

The heteroduplex joint, a splice containing paired strands from each of two DNA molecules is a key feature of homologous genetic recombination[1,2]. The formation of such a lap joint ensures that heterologous chromosomes do not recombine; presumably the degree of homology determines the frequency of crossing over between related but non-identical chromosomes. On the other hand, according to the current ideas on recombination, the formation of heteroduplex joints is not a stringent process. Genetic evidence supports the view that the classical phenomena of meiotic gene conversion and aberrant meiotic segregation result in part from the inclusion of mismatched base pairs in heteroduplex joints, and the subsequent correction of some of these mismatched pairs before replication[3–5]. Thus meiotic gene conversion signals one kind of departure from perfectly faithful pairing. The association of increased mutation frequencies with crossing-over is another kind of departure from fidelity in recombination[6–8]. Little is known about the effect of imperfect homology either on the initial pairing of DNA molecules, or on the formation and extension of heteroduplex joints. The nucleotide sequences of phages ΦX174 and G4 are related, but differ by 33% of bases in the coding regions. Here we show using combinations of ΦX174 and G4 DNA, that *Escherichia coli* RecA protein catalyses the formation of joint molecules with many mismatched base pairs, but only if one of the molecules is superhelical. By contrast, in the absence of RecA protein, superhelicity does not cause ΦX174 and G4 DNA to form D-loops spontaneously at any temperature between 37 and 75 °C. These observations focus attention on the role of RecA protein in unwinding DNA, and on superhelicity as a factor that can lessen the fidelity of homologous pairing.

Recent studies of RecA protein, which is essential for genetic recombination of *E. coli*[9,10] have shown that this single purified protein can promote two central steps of genetic recombination *in vitro*, namely synapsis, the pairing of homologous molecules, and strand exchange, which produces long heteroduplex joints[11–13]. Synapsis is experimentally separable from the formation of heteroduplex joints: RecA protein can pair a single strand with homologous duplex DNA in the absence of a free end in any of the strands[11]; and *E. coli* topoisomerase I, acting on these intermediates can interwind a single strand with its complement in duplex DNA[12]. When a free end exists, for example in the combination of linear duplex DNA and circular single-stranded DNA, RecA protein causes the formation of long heteroduplex joints[11] by driving strand exchange in one direction[14–16]. RecA protein can also cause the uptake of a linear single strand by superhelical or non-superhelical DNA to form a particular kind of heteroduplex joint called a D-loop[17,18].

In vivo, both synapsis and heteroduplex formation presumably contribute to the fidelity of homologous pairing. In experiments on the reactions promoted *in vitro* by RecA protein, we have observed effects of imperfect homology on both synapsis and strand exchange[12,15]. RecA protein makes joint

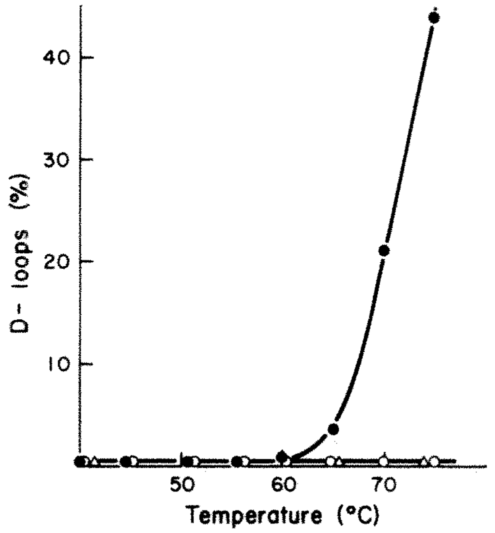

Fig. 1 Spontaneous formation of D-loops plotted against temperature. Superhelical DNA, and fragments of single-stranded DNA, each at 80 μM, were heated for 40 min at the temperature indicated in 20 μl reaction mixtures containing 10 mM Tris (*p*H 7.5), 1 mM EDTA and 200 mM NaCl. D-loops were assayed according to Beattie *et al.*[25]. The superhelical DNA in all reaction mixtures was from ΦX174. ●, ΦX174 single-stranded fragments; ○, G4 single-stranded fragments; △, no single-stranded DNA.

Table 1 Superhelicity promotes the pairing of ΦX174 and G4 DNA by RecA protein

Duplex DNA, 4.2 μM, and single-stranded DNA, 6.0 μM, were incubated for 30 min at 37 °C in 20 μl reaction mixtures containing 31 mM Tris (*p*H 7.5), 100 μg ml bovine serum albumin, 25 mM $MgCl_2$, 1.2 mM ATP and 3.0 μM RecA protein. When the duplex DNA was superhelical, the reaction was stopped by adding 130 μl of 25 mM EDTA (*p*H 8.5) and 0.5% Sarkosyl. Aliquots of 40 μl were diluted in 2 ml of 1.5 M NaCl/0.15 M Na citrate, held at 41 °C for 4 min, diluted in cold NaCl/Na citrate, and filtered through nitrocellulose[11]. When the duplex DNA was nicked circular or linear DNA, we stopped the reaction by adding 100 μl of 25 mM EDTA (*p*H 8.5) and diluted it in cold 1.5 M NaCl/0.15 M Na citrate before filtration.

Sequences are taken from Godson[21,22]. For G4 DNA, the sequence shown is that of the viral strand, proceeding 5′ to 3′ from the *Pst*I site in gene A; for ΦX174 it is the sequence from a different *Pst*I site in gene A. Letters in bold type represent differences between the corresponding sequences of ΦX174 and G4. The brackets separate continuous runs of homologous bases from regions containing differences, and the numbers above the brackets indicate the number of perfectly matched bases.

molecules from mixed pairs of circular single-stranded DNA and linear duplex DNA of fd and M13, whose nucleotide sequences differ by 3% of bases[19,20]. However, even these relatively sparse mismatches can stop the unidirectional growth of heteroduplex joints[15]. When we did the same experiment with pairs of ΦX174 and G4 DNA, no joint molecules were formed. Neither fragments nor circular single-stranded ΦX174 DNA formed joint molecules with linear duplex G4 DNA, whereas the perfectly homologous combination of single-stranded G4 DNA with duplex G4 DNA yielded joint molecules. Parallel observations were made with single-stranded G4 DNA and duplex ΦX174 DNA (Table 1*a*).

The pairing by RecA protein of circular viral single strands with linear duplex DNA is a precise reaction in which a heteroduplex joint forms preferentially at the 3′ end of the complementary strand and grows in one direction away from the end[11,14,15]. When the linear molecules are produced by restriction cleavage of circular duplex DNA, the formation of heteroduplex DNA begins at a specific sequence. Thus with regard to the pairing of ΦX174 and G4 DNA, the published nucleotide sequences reveal the degree of homology at the sites from which heteroduplex formation begins. The nucleotide sequences of the appropriate ends of linear duplex ΦX174 DNA and G4 DNA are listed in Table 2[21,22]. A short distance from each end, there is a subterminal region in which 1/3 to 1/2 of bases do not match. Experiments reported elsewhere have shown that a density of mismatches as low as 1 base pair in 10 can retard the growth of heteroduplex joints promoted by RecA protein[15]. In the case of relaxed ΦX174 and G4 DNA the greater density of mismatched sequences blocks not only the enlargement of heteroduplex joints, but also the formation of any stable joint molecules by RecA protein. Superhelicity, however, overcomes the inability of RecA protein to pair these partially homologous molecules. When we reacted fragments of single-stranded ΦX174 DNA and superhelical G4 DNA, or vice versa, with RecA protein, we observed the formation of joint molecules (Table 1*b*). The mixed combinations of circular single-stranded DNA with superhelical DNA (Table 1*b*) or of fragments with nicked circular DNA (Table 1*c*) did not yield joint molecules.

Table 3 The size of D-loops made by RecA protein from partially homologous fragments and superhelical DNA

	Superhelical DNA	
Fragments of ssDNA	ΦX174	G4
ΦX174	340±110*	220±120
G4	250±130	320±100

D-loops were made with superhelical DNA and single-stranded fragments as for Table 1. Measurements of the lengths of D-loops by electron microscopy were made as described previously[23].

* 14–19 D-loops were measured in each sample.

The joint molecules made by combinations of ΦX174 and G4 DNA had the electron microscopic appearance of D-loops (data not shown). Measurement showed that the mean lengths of D-loops in the mismatched combinations exceeded 200 base pairs, corresponding to about 2/3 to 4/5 of the lengths of D-loops made in perfectly matched combinations (Table 3). Since the median length of perfectly matched sequences in ΦX174 and G4 is 14 bases and since no perfectly homologous sequence exceeds 30 bases, the D-loops made by ΦX174 and G4 must contain many mismatched base pairs. For example there is a stretch of 30 homologous bases in gene D; in the 200 bases preceding and following this stretch there are 65 and 42 mismatched bases. The other 3 homologous runs of 28–30 bases are flanked by similarly large numbers of mismatched bases[22].

Table 4 Summary of observations on fidelity of homologous pairing promoted by RecA protein

	Fragmented	Nicked circular	−	This paper
	Fragmented	Superhelical	+	This paper
fd+M13	Circular	Linear	+	15
	Circular	Superhelical	−	Unpublished

When superhelical DNA containing D-loops is nicked, the D-loops promptly dissociate by spontaneous branch migration[24]. We compared the dissociation of D-loops made from homologous and mixed combinations of ΦX174 and G4 DNA. D-loops made from mixed combinations dissociated more rapidly, as expected for shorter D-loops and for D-loops containing mispaired bases (data not shown).

The experiments described above show that superhelicity promotes the formation by RecA protein of heteroduplex joints that contain many mismatches. No measurable formation of D-loops occurred in 60 min at 37 °C in the absence of RecA protein, even when the DNA was perfectly homologous (Fig. 1). The requirement of RecA protein for the formation of D-loops from ΦX174 plus G4 DNA is further shown by experiments in which we tried to make D-loops from ΦX174 and G4 DNA by annealing[25]. Homologous pairs of DNA formed 21–24% D-loops in 30 min at 75° C, but the mixed combinations G4 superhelical DNA and ΦX174 single-stranded fragments, or vice versa, formed none. In the absence of RecA protein, we did not observe the spontaneous formation of D-loops by ΦX174 superhelical DNA and fragments of G4 DNA at any temperature between 37° and 75 °C (Fig. 1).

Thus observations on the pairing of DNA from related small DNA phages have shown that the basis for discriminating a high degree of relatedness from perfect or nearly perfect homology exists in the mechanism by which RecA protein promotes homologous pairing (summarized in Table 4). We can begin to relate the effects of mispairing to the two steps in the reaction, namely synapsis and heteroduplex formation. The sequences of fd and M13 differ by 3% of bases; whereas ΦX174 and G4 differ by 33% of bases in the coding regions which comprise 95–96% of their genomes[19-22]. These different degrees of potential mismatching have distinguishable effects. According to previous observations on the joint action of RecA protein and *E. coli* topoisomerase I, the imperfect homology of ΦX174 and G4 DNA interferes with synapsis, a step that precedes the formation of an extensive heteroduplex joint[12]. However, if the single-stranded DNA is fragmented, and the duplex DNA is superhelical, then even 33% nonhomology does not bar the formation of joint molecules, although the frequency is reduced relative to completely homologous molecules. The 3% nonhomology of fd relative to M13 permits the formation of joint molecules in non-superhelical DNA, but interferes with the growth of heteroduplex joints that is actively promoted by RecA protein[15]. Nonetheless, many mismatched base pairs are included in the joint molecules formed by fd and M13 DNA, and correspondingly more mismatched base pairs are included in the joint molecules that are formed by ΦX174 and G4 DNA when superhelicity favours the reaction.

Although spontaneous uptake of homologous single-stranded fragments by superhelical DNA is driven by the energy of superhelix formation, additional energy in the form of heat is required to make the reaction go at readily measured rates. On several grounds, we suggested that this energy unwinds the helix at potential nucleation sites and that this unwinding is the rate-limiting step. Following nucleation, the superhelix energy causes the D-loop to grow because it stabilizes the product, which is a less constrained structure than the original superhelix[25]. In the present experiments, the failure of ΦX174 and G4 DNA to form D-loops in the thermal reaction is presumably due to lack of nucleation of imperfectly matched sequences at high temperatures, in other words to instability of a nascent heteroduplex joint. RecA protein may promote the pairing of G4 and ΦX174 because it unwinds the helix at 37 °C (ref. 26) at which temperature even imperfectly paired sequences may form a nucleus that can be enlarged by the energy of superhelix formation. According to this interpretation, RecA protein, using the energy of ATP, replaces the role of thermal energy in unwinding the helix so that nucleation can occur. In the absence of superhelicity, RecA protein fails to pair ΦX174 and G4 DNA because there is a net loss of perfectly paired bases without the offsetting entropic gain that is associated with formation of a D-loop in superhelical DNA[25].

With regard to recombination, and possibly mutagenesis, the significant observation reported here is that RecA protein, using superhelical DNA as the recipient of a strand transfer, can make heteroduplex joints containing many mismatches.

We thank Lynn Osber for technical assistance and John Flory for helpful comments on the manuscript. This research was sponsored by grant NP 90G from the American Cancer Society and grant USPHS CA 16038-07 from the NCI.

Three classes of mouse H–2 messenger RNA distinguished by analysis of cDNA clones

David Cosman, George Khoury & Gilbert Jay

Laboratory of Molecular Virology, National Cancer Institute,
National Institutes of Health, Bethesda, Maryland 20205, USA

The major histocompatibility complex (MHC) is composed of a set of linked genes encoding proteins involved in the host's immune response[1]. A subset of these proteins are the classical transplantation antigens, which are responsible for rapid allograft rejection and are involved in the associative recognition of foreign antigens by cytotoxic T cells[1,2]. Three different genetic loci coding for the transplantation antigens in humans (HLA-A, -B and -C) and in mice (H–2K, D and L) have been identified[3,4]; they are highly polymorphic[1]. The recent molecular cloning of HLA[5,6] and H–2[7,8] cDNA sequences provide the basis for detailed characterization of the genetic organization and expression of the MHC. We report here the identification, by analysis of cDNA clones, of at least three distinct classes of H–2 messenger RNAs that can be differentiated on the basis of their disparate 3′-non-translated regions, and describe an unusual sequence arrangement in one class of H–2-like molecule.

An adult liver cDNA library, derived from SWR/J mice (*q* haplotype) and cloned into the *Pst*I site of pBR322 (ref. 9), was screened by hybridization using as a DNA probe the insert from the HLA cDNA clone of Sood *et al.*[6]. Approximately 150,000 colonies were screened and 30 clones isolated. Excision of the DNA inserts from each of the putative H–2 clones, by digestion with *Pst*I, generated multiple fragments which show extensive overlaps between the clones (Fig. 2*a*), suggesting that most of the clones are related to each other.

Clone pH2 was chosen for further analysis. The entire DNA insert at the *Pst*I site of pBR322 is ~1,150 base pairs (bp) long and contains three internal *Pst*I cleavage sites (Fig. 1). The order of the four *Pst*I fragments is C (220 bp), B (250 bp), A (530 bp) and D (170 bp). Nucleotide sequence analysis of each fragment has shown that pH2 is highly homologous to the H–2 cDNA clones isolated by others[7,8] and to the known amino acid sequences of H–2 transplantation antigens[4]. The entire pH2 insert extends from the codon for amino acid 86 (numbered according to the sequence of H–2K$^{\mathrm{b}}$)[4] to the 3′ end of the mRNA, including the presumptive polyadenylation signal, AAUAAA, located 11 nucleotides from the poly(A) tract (data not shown). The sequences determined corresponded to amino acids 86–138 from within fragment C, 198–236 from fragment B and 237–315 from fragment A.

0028–0836/82/010073—04$01.00

Clone pH2 was used as a prototype with which to compare the other cDNA clones. Individual *Pst*I fragments of pH2 DNA were ^{32}P-labelled by nick-translation and hybridized to Southern blots of *Pst*I digests of DNA from the other recombinant plasmids. Figure 1 shows the maps for nine of the cDNA clones obtained by this cross-hybridization. During the mapping experiments, we noted many similarities between the clones. Most of the clones have either a 530- (pH2, 16, 18) or 570- (pH8, 12, 19, 6) bp cross-hybridizing A fragment (Fig. 2*b*), and a common 250-bp B fragment. The A and B fragments are internal fragments in pH2 (see Fig. 1). The clones differ extensively in the size of their 5′ fragments, a presumed artefact of cDNA synthesis, as well as in their 3′ D fragments. In addition, the D fragment of pH2, which contains entirely 3′-non-coding sequences immediately adjacent to the poly(A) tract, did not cross-react to any extent with the 3′-non-coding D fragments of many of the other clones.

To determine whether the 3′-non-coding regions of the various clones may be useful for distinguishing different classes of H-2 molecule, the *Pst*I D fragment (170 bp) from pH2, the D_1 fragment (185 bp) from pH8 and the D_2 fragment (135 bp) from pH12 were purified, labelled by nick-translation and hybridized to Southern blots of *Pst*I digests of the same set of nine plasmid DNAs (Fig. 2*c–e*). Figure 2*c* shows that the D fragments of clones pH2, pH16 and pH18 are indistinguishable on the basis of size or extent of cross-hybridization. The pH2 D fragment did not cross-react with any of the other clones. The pH8 D_1 fragment hybridized to itself (Fig. 2*d*) and pH25, pH26 and pH35 (data not shown). On the other hand, the pH12 D_2 fragment hybridized to a similar-sized fragment from pH19 (Fig. 2*e*) and to pH24 and pH31 (not shown). Thus at least three classes of H-2 mRNA molecule can be defined by differences in their 3′-non-coding regions, represented by clones pH2 (pH16, pH18), pH8 (pH25, pH26, pH35) and pH12 (pH19, pH24, pH31). Although clones pH5, pH6 and pH7 cannot be classified on the basis of this analysis because they lack a D fragment, they are not in the same class as pH2 (see below and Fig. 2*f*).

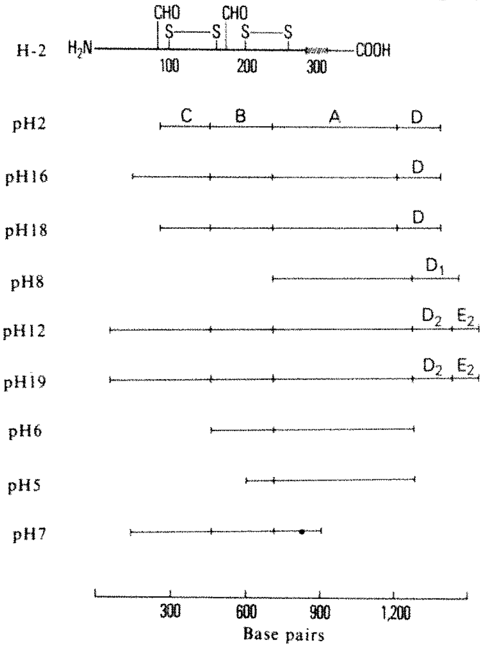

Fig. 1 The *Pst*I restriction maps of nine H-2 cDNA clones. As the recombinant plasmids were constructed by the dG–dC tailing method[9], the cDNA inserts could be excised using *Pst*I. The multiple restriction fragments generated by *Pst*I cleavage were ordered by analysis of partial digestion products. The orientation and location of each fragment derived from clone pH2 DNA relative to the linear structure of the H-2 antigen were determined by DNA sequence analysis. The map for each of the nine clones is presented in alignment with a schematic representation of the linear structure of the H-2 antigen, including the locations of the carbohydrate side chains (CHO), the disulphide bridges (S–S) and the membrane-binding region (hatched).

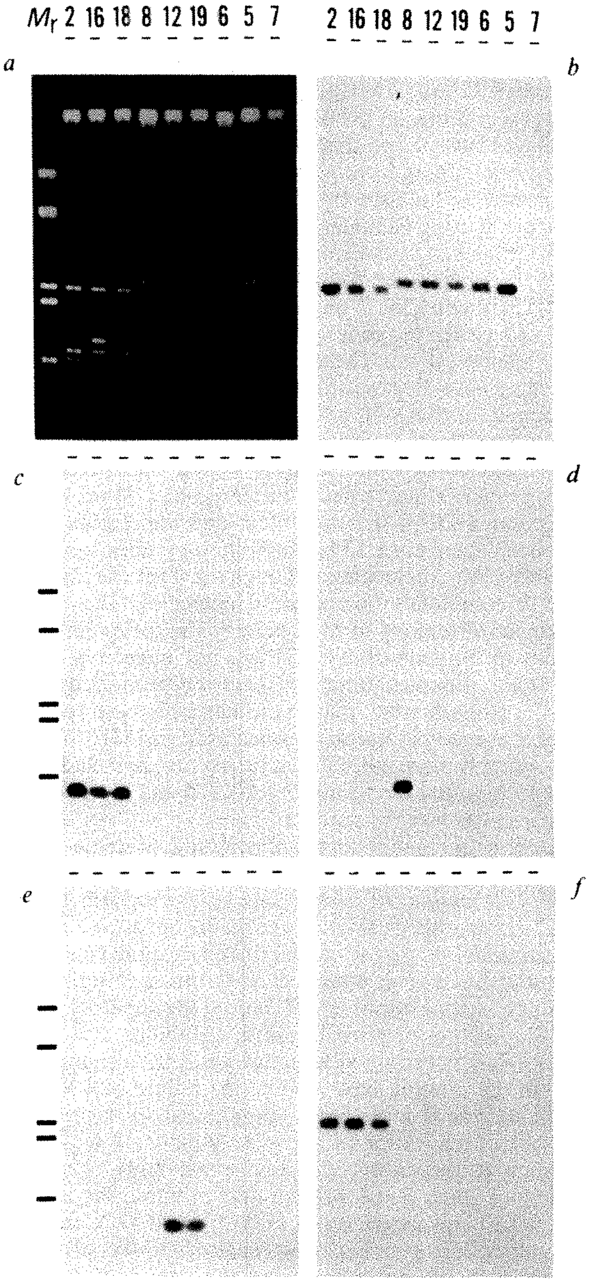

Fig. 2 Identification of different classes of H-2 cDNA clones by cross-hybridization analyses. Nine plasmid DNAs were digested with *Pst*I and fractionated by electrophoresis on 1.6% agarose gels (*a*). The DNA fragments were transferred from the gels to nitrocellulose sheets by the method of Southern[12]. The sheets were prehybridized for 2–3 h at 65 °C in 3×SSC (1×SSC = 0.15 M NaCl, 0.015 M Na citrate), 5×Denhardt's (1× Denhardt's = 0.02% Ficoll, 0.02% polyvinylpyrolidone, 0.02% bovine serum albumin), 0.1% SDS, before hybridization for 16 h in the same conditions with one of several ^{32}P-labelled DNA probes (*b–f*). DNA fragments used as probes were generated by digestion with the appropriate restriction enzymes and fractionated by electrophoresis through 5–8% polyacrylamide gels. The appropriate DNA bands were eluted and ^{32}P-labelled by nick-translation[13] to a specific activity of $0.5\text{–}2\times10^8$ c.p.m. per µg. The 23-bp DNA fragment (*f*) was self-ligated with T4 DNA ligase before nick-translation. Following hybridization, the nitrocellulose sheets were washed extensively in 3×SSC, 0.1% SDS at 65 °C, dried and exposed to Kodak XAR-5 films. The molecular weight markers (M_r), derived from simian virus 40 DNA by *Hin*dIII digestion, were 1,768, 1,169/1,118, 526, 447 and 215 bp long. *a* Is a picture of an ethidium bromide-stained gel; autoradiograms of Southern blots were obtained with the following DNA probes: *b*, pH2 *Pst*I A fragment; *c*, pH2 *Pst*I D fragment; *d*, pH8 *Pst*I D_1 fragment; *e*, pH12 *Pst*I D_2 fragment; and *f*, the 23-bp *Hin*fI–*Sau*3A subfragment from the pH2 *Pst*I A fragment.

Fig. 3 Comparison of the amino acid sequence around the transmembrane region of the classical H-2 antigen with the predicted amino acid sequence of the corresponding region from clone pH2. *a*, Autoradiogram of a sequencing gel showing the nucleotide sequence of the antisense strand of pH2 DNA around amino acids 280–300. The *Pst*I A fragment of pH2 DNA was cleaved with *Mbo*II and end-labelled with [γ-^{32}P]ATP by the exchange reaction[14]. A 220-bp fragment was purified by polyacrylamide gel electrophoresis and recleaved with *Rsa*I to give two fragments. The larger of these was subjected to sequence determination by a modification of the Maat–Smith procedure[15,16]. This sequence has been confirmed by analysis of both strands using the Maxam–Gilbert procedure[14]. *b*, Comparison of the pH2 sequence with the corresponding sequence from two previous isolates, pH-2II (ref. 8) and pH-2^d-3 (ref. 10). The sequences are aligned for maximum homology showing the 13-bp deletion of pH2 relative to pH-2II and pH-2^d-3. All differences in nucleotide sequences are indicated by ●. The numbers correspond to the amino acid sequence of H–$2K^b$ (ref. 4).

The pH2 class can be further distinguished from the pH8 and pH12 classes by its slightly faster-migrating A fragment (Fig. 2*a*). DNA sequence analysis of pH2 showed an unusual feature in the part of the A fragment expected to encode the transmembrane portion of the H-2 molecule, from amino acids 284–307 (for reviews on the structure of the H-2 molecule, see refs 3, 4). Comparison of the sequence of the presumed transmembrane region, which is comprised of 25 uncharged and nonpolar amino acids, from two previous isolates from other laboratories, pH-2II (ref. 8) and pH-2^d-3 (ref. 10), showed perfect conservation of hydrophobic residues (Fig. 3). Analysis of the corresponding region in pH2 indicated that (1) there are extensive nucleotide and amino acid substitutions at the beginning of the transmembrane region, between positions 284 and 290, with three out of six hydrophobic residues being replaced by charged or polar amino acids; (2) this is followed by a deletion of 13 bp, which removes the codons for amino acids 291–294, located in the middle of the transmembrane region, and also the first base of the codon for amino acid 295, resulting in a shift in the reading frame; and (3) this frameshift results in the introduction of a termination codon 34 nucleotides downstream at amino acid position 302. Figure 3 shows the nucleotide sequence and predicted amino acid sequence around this region of the pH2 molecule. Note that three charged amino acids (His 286, Asp 289, Lys 296), as well as three polar residues (Ser 285, Ser 294, Pro 293), are now found interspersed throughout that region of the pH2 molecule which is equivalent to the hydrophobic transmembrane region of the classical H-2 antigen.

To determine whether this unusual sequence was present in any other cDNA clones, we purified from pH2 the 23-bp *Hinf*I–*Sau*3A restriction fragment that spans amino acids 281–288. Following self-ligation and ^{32}P-labelling by nick-translation, it was hybridized to Southern blots of *Pst*I-restricted plasmid DNAs (Fig. 1*f*). Only those clones representing the pH2 class, and containing a smaller 530 bp, rather than 570 bp, A fragment, hybridized strongly to this probe. These clones (pH2, pH16 and pH18) also have indistinguishable D fragments (Fig. 2*c*). Direct sequence analysis of pH16 further confirmed its identity to pH2 in this region of the molecule. This unusual pH2-like sequence is not a general feature of the transplantation antigens present in liver cells of mice of the *q* haplotype. In fact, clone pH7 has been found to have a classical hydrophobic transmembrane sequence from amino acids 280 to 293, at which point the clone is terminated by dG-dC tails (Fig. 1). The very weak hybridization of the 23-bp pH2-specific probe to pH8, -12, -19, -6, -5 and -7 (Fig. 2*f*) is probably due to the homology between amino acids 281 and 284 (see Fig. 3).

The 250-nucleotide sequence immediately upstream from this unusual region of pH2 has been determined and contains neither in-frame nonsense codons nor frameshifts (data not shown). This region, between amino acids 198 and 279, shows 88% homology to the H-$2K^b$ amino acid sequence[4]. The presence of this unusual sequence in liver mRNA raises the possibility that the mRNA represented by pH2 encodes a shortened form of the H-2 antigen (301 amino acids) that might have a different biological function. Such a truncated antigen is expected to contain the entire biologically active portion of the H-2 molecule. The absence of a hydrophobic region in this putative polypeptide makes it unlikely that it could be inserted into the plasma membrane. The loss of the C-terminal hydrophilic tail would preclude it from interacting with cytoplasmic components. It is possible that such a molecule could be secreted.

Although an altered form of the H-2 antigen has not previously been described, we have observed a protein of molecular weight 35,000 that can be immunoprecipitated by anti-H-2 antiserum from cell-free translation products of liver mRNA (unpublished results). It remains to be determined whether this protein is the product of the mRNA represented by pH2. Until a protein product of this mRNA is identified, we cannot exclude the possibility that pH2 represents a transcriptionally active H-2-like pseudogene.

This study demonstrates that different classes of H-2 cDNA clones can be identified on the basis of non-homologous 3′-untranslated sequences. The classes cannot yet be assigned to the H-2K, -D or -L loci as complete amino acid sequences from the *q* haplotype are not available. This observation should provide both a method for differentiating between members of a multi-gene family and a clearer understanding of their genomic organization and expression.

After this manuscript had been submitted, Steinmetz *et al.*[11] published the sequence of an H-2-like pseudogene with unusual changes in the transmembrane region that are distinct from those in pH2. It was not determined whether this pseudogene was transcribed.

We acknowledge the generous gifts of the HLA-B cDNA plasmid from Dr Sherman Weissman and the mouse liver cDNA library from Drs John Monahan and Michael Tocci.

Cloning and analysis of cDNAs encoding plant storage protein precursors

Ronald R. D. Croy, Grantley W. Lycett, John A. Gatehouse, Jennifer N. Yarwood & Donald Boulter

Department of Botany, University of Durham, Science Laboratories, South Road, Durham DH1 3LE, UK

The major storage protein in many legume seeds is legumin, a hexameric molecule of molecular weight (M_r) 360,000–400,000 consisting of six subunit pairs, each of which comprises a 40,000-M_r, acidic polypeptide linked by disulphide bonds to a 20,000-M_r, basic polypeptide[1]. We have recently shown that these subunit pairs are synthesized, *in vivo* and *in vitro* in *Pisum* and *Vicia*[2,3], as a 60,000-M_r precursor polypeptide, putatively containing one copy each of the acidic and basic subunits covalently linked together. We describe here the cloning and identification of cDNA sequences coding for the legumin precursor. Additionally, we have used these cDNAs to verify that the legumin mRNAs are of sufficient size to code for the precursor and to demonstrate the presence of four single-copy legumin genes in genomic DNA. Possible mechanisms for the processing of the legumin precursor are discussed. Identification of cloned cDNA sequences coding for vicilin, the secondary storage protein of *Pisum sativum*[4], is also reported.

Double-stranded DNA complementary to poly(A)$^+$ RNA from developing seed cotyledons was prepared[43] and cloned in plasmid pBR322[5,6] as described in Fig. 1 legend. Transformed colonies strongly hybridizing to mRNA or cDNA probes were selected as putative legumin and vicilin cDNA clones and plasmid 'minipreps' made according to Klein *et al.*[7]. Southern 'blots' of cDNA inserts, excised from the recombinant plasmids, strongly hybridized mRNA and cDNA probes, further confirming the presence of cDNA inserts. The cDNA inserts were used to prepare and identify complementary mRNAs by hybrid-selected translation[8,9] (Fig. 1).

An initial selection of 12 clones contained 6 cDNAs encoding vicilin 50,000 and 47,000-M_r subunits[4,10–13], two encoding the legumin 60,000-M_r precursor[2,3] and several others coding for unidentified polypeptide products (Fig. 1).

Physical maps of two legumin cDNAs have been constructed from restriction endonuclease analyses and are shown in Fig. 2 together with the sequencing strategies. The legumin cDNA, pRC 2.2.4, identified by hybrid-selected translation, has been completely sequenced and corresponds to a 638-nucleotide sequence from the 3′ end of the legumin mRNA (Fig. 3). There is, in addition, a polyadenylated sequence at the 3′ terminus. The second legumin cDNA (pRC 2.11.7), selected by screening the cDNA clone bank with pRC 2.2.4 cDNA, has been partially sequenced. It is essentially identical to 2.2.4, but is larger by about 150 nucleotides extending towards the 5′ end of the message.

The close agreement of the predicted amino acid composition, tryptic peptide and N-terminal sequence data with published data[1,14,15] unequivocably identifies the nucleotide sequence as that of a legumin cDNA and also locates the basic (20,000 M_r) subunit at the 3′ end of the legumin messenger coding sequence. The additional coding sequence of pRC 2.11.7 shows that the amino acid sequence extends unbroken upstream beyond the N terminus of the basic subunit for at least 30 amino acids, presumably past or approaching the C terminus of the acidic subunit[1,16]. There are no termination or initiation codons in this pre-N-terminal sequence, confirming the legumin precursor theory[3]. The sequence data also show that the legumin mRNA has a significant non-coding sequence between the coding sequence and the poly(A) tail. This 137–nucleotide sequence is A+T rich, in common with many other eukaryotic mRNAs, and contains the hexanucleotide sequence -AATAAA-, about 20 nucleotides upstream from the 3′ end, as also found in other eukaryotic mRNAs[17–22].

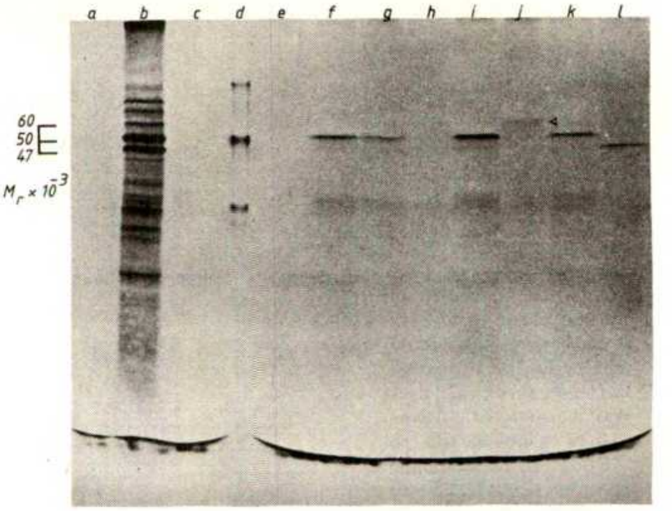

Fig. 1 Identification of recombinant plasmids containing cDNAs by translation of hybrid-selected mRNAs. Polyadenylated RNA, purified from 14-day-old pea cotyledons, was used to synthesize double-stranded cDNA by avian myeloblastosis virus reverse transcriptase and DNA polymerase I as described previously[43]. The double-stranded cDNA was cloned in the *Bam*HI site of pBR322 after attachment of *Bam*HI synthetic oligonucleotide linkers, essentially by the method of Sippel *et al.*[6]. 1 μg of ^{32}P- or ^{3}H-labelled cDNA, blunt-ended with DNA polymerase I, was ligated to 400 pmol of 5′-phosphorylated linkers for 15 h at 12.5 °C (ref. 6). After digestion with an excess of *Bam*HI, the cDNA was fractionated on a Sepharose 6B column (100 mm × 15 mm diameter) and the fractions containing the largest cDNAs were pooled and recovered by alcohol precipitation. pBR322 (5 μg) linearized with *Bam*HI, was treated with alkaline phosphatase to remove the 5′-phosphate groups (to prevent self-ligation and non-recombinant transformations[6,44]) and after extensive phenol extraction the plasmid was passed through a Sephadex G-50 column and recovered by alcohol precipitation. The cDNA was ligated to the plasmid for 48 h at 12.5 °C. 0.5–1.0 μg of the recombinant DNA was used to transform competent cells prepared from RecA$^-$ or BedBC$^-$ strains of *Escherichia coli* K-12, after 24 h incubation in calcium chloride to enhance competence[22]. Transformants were selected on ampicillin plates and screened by colony hybridization on nitrocellulose filters with ^{32}P-labelled cDNA and mRNA[45]. Hybridizations were performed in the presence of polyadenylic acid to prevent any non-specific binding of probes to poly(dT-dA) regions in the clones[44]. Probing with pea ribosomal RNA showed the complete absence of any ribosomal cDNA clones. cDNA containing plasmids, purified by the method of Clewell[4,6] and Katz *et al.*[47], were restricted with *Bam*HI to excise the cDNA inserts, and 20–30 μg aliquots of total DNA were denatured and applied to freshly prepared diazobenzyloxymethyl paper[9] as described by Smith *et al.*[8]. Poly(A)$^+$ mRNA was allowed to hybridize, 5 μg per filter, to the plasmids and specifically bound mRNAs were eluted[8] and translated in the reticulocyte lysate system[3]. Translation products labelled with ^{3}H-leucine were separated and visualized by SDS-polyacrylamide gel electrophoresis followed by fluorography[48]. Track *b* shows the translation products from total poly(A) mRNA: tracks *a* and *c* show, respectively, endogenous translation products from RNA nonspecifically bound to pBR322. Tracks *e*–*l* show the translation products from mRNAs specifically bound to cDNA plasmids. pRC 2.1.7, 2.1.8, 2.1.18, 2.1.20, 2.2.1, 2.2.4 (band indicated with an open arrow), 2.2.5, 2.2.10, respectively. (Track *d* shows a ^{3}H-labelled standard protein preparation.) Legumin 60,000 M_r precursor and vicilin 50,000 and 47,000 M_r precursors were identified as described previously[3,4]. Characterized and ^{32}P-nick translated[28] cDNAs, prepared as described in Fig. 4 legend, were used to rescreen the cDNA clone bank for related but longer cCNA sequences. Clones were arrayed and grown on nitrocellulose filters and subjected to colony hybridization using the legumin cDNA insert from pRC 2.2.4. In this way the complementary and larger legumin cDNA, pRC 2.11.7, was detected and isolated.

As further evidence for synthesis of legumin as a single polypeptide precursor, we have determined the size of the

0028-0836/82/010076—04$01.00

legumin mRNA. Total and polyadenylated RNA preparations from developing cotyledons and leaves were denatured by glyoxylation[23] and size fractionated by agarose electrophoresis, and after transfer to nitrocellulose paper[24], the 'Northern' blots were probed with ^{32}P-labelled legumin cDNAs (Fig. 4). Legumin cDNA hybridized strongly to a single component in both seed RNA preparations corresponding to a 19S mRNA (2.2×10^3 bases), sufficiently long to code for a precursor polypeptide of at least 60,000 M_r. Although hybridization of legumin cDNA to smaller mRNA species was observed in seed polyadenylated RNA (Fig. 4), the binding was never to discrete mRNA sizes and was unique to polyadenylated preparations. No such hybridization was observed in total seed RNA preparations, indicating the absence of small mRNA species which may have coded for the smaller (basic) polypeptide components found in legumin isolated from mature seeds. We conclude from these results that extensive degradation of the 19S legumin mRNA occurs during the preparation of polyadenylated RNA, in agreement with the reports of Dunham *et al.*[25]. There was also no hybridization of the probes to any components in the leaf polyadenylated RNA preparations, verifying the tissue-specific expression of the storage protein genes[26].

We have also used the legumin cDNAs to probe for the homologous sequences in genomic DNA. Pea genomic DNA was prepared from leaf tissue[27] and equal aliquots were digested to completion with *Eco*RI or *Hin*dIII restriction endonucleases (which do not cut within the cDNA sequence) (Fig. 5). After separation on agarose gels, the genomic DNA fragments were blotted on to nitrocellulose paper[24] and then hybridized to an excess of ^{32}P-nick-translated[28] cDNA insert (specific activity $\geq 2 \times 10^7$ c.p.m. per μg) from pRC 2.2.4 (Fig. 5). Various amounts of linearized pRC 2.2.4 corresponding to different gene copy numbers were also included on the gels[29] (Fig. 5). We have only been able to detect four *Eco*RI genomic fragments (excluding any intron sites) hybridizing to legumin cDNA and an estimate of the intensities of hybridization to genomic fragments and cDNA plasmids indicates a single gene copy per fragment and therefore an apparent maximum complement of four legumin genes per haploid genome. This agrees with the recent reports of Spencer and Higgins[30] of a set of at least three legumin precursors found *in vivo*, and of J.A.G. *et al.* (unpublished) of at least three legumin precursors *in vitro*. Other reports have indicated that up to four major legumin species exist in mature pea seeds, depending on the genetic line[16,31–34]. However, there have also been many reports of a greater number of minor legumin species in pea and other legumes, based on polypeptide

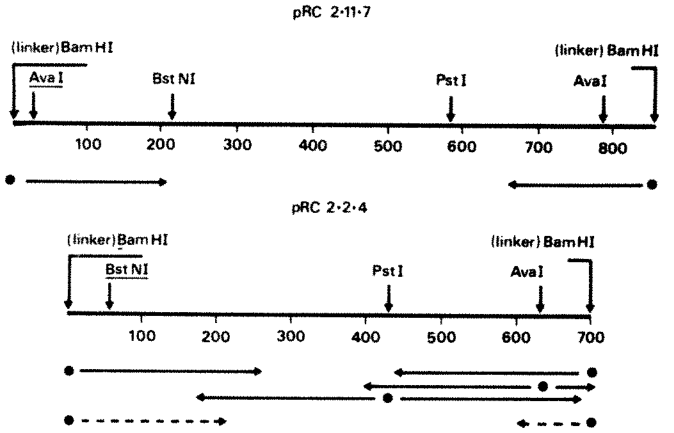

Fig. 2 Restriction maps of cDNAs from plasmids pRC 2.11.7 and pRC 2.2.4 showing the positions of restriction enzyme targets used in the sequencing experiments. The horizontal scales represent nucleotide base pairs from the 5′ end of the coding strand. Numbers of nucleotide base pairs in pRC 2.11.7 correspond to the scale in the nucleotide sequence (Fig. 3). The horizontal arrows indicate the extent of the fragments sequenced and the direction of sequence reading from the 5′-labelled ends (●). Sequencing was by the method of Seif *et al.*[49] (continuous arrows) or that of Maxam and Gilbert[50] (broken arrows).

Fig. 3 Composite cDNA sequence coding for the legumin basic subunit. The figure shows the DNA (mRNA) sequence (line *a*) derived from pRC 2.11.7 and pRC 2.2.4. Numbering in the nucleotide sequence corresponds to that of pRC 2.11.7 in Fig. 3. The asterisk at position 787 indicates the only position at which the two sequences differ, with an adenine residue occurring in 2.2.4 and a thymine residue in 2.11.7. Restriction endonuclease sites are overlined and the termination codon is underlined, as are the overlapping AATAAA hexanucleotide sequences at the 3′ end of the mRNA. DNA sequencing was by the methods of Seif *et al.*[49] or Maxam and Gilbert[50]. Where the method of Seif *et al.*[49] was used, the products of forward and backward reactions were pooled before lyophilization. In both cases, end-labelled DNA fragments were prepared according to Maxam and Gilbert and sequencing gels (6 and 8% polyacrylamide) were prepared as described by Smith[51] and run at 1,500 V. The predicted amino acid sequence (line *b*) was obtained from the DNA sequence by the use of a computer program (provided by Dr M. D. Watson). Line *c* shows peptide amino acid sequences matching the predicted sequence. The N-terminal peptide sequence was obtained from the published data of Casey *et al.*[15] and all other sequences (underlined) were obtained by sequencing purified tryptic peptides from the legumin basic polypeptides (J.N.Y., in preparation). Basic subunits were isolated from total legumin by ion-exchange chromatography in formamide, as described by Gatehouse *et al.*[37]. The separated basic subunits were extensively dialysed against distilled water and lyophilized. Tryptic digestions were carried out for 6 h at 37 °C (100/2 w/w) and the peptide mixture lyophilized before separation by HPLC. The tryptic peptides were separated on a reverse-phase column (C18, 10μ, Varian MCH-10) using a trifluoroacetic acid/acetonitrile gradient (0–70% acetonitrile). Separated peptides were collected and lyophilized before being sequenced by the DABITC method of Chang *et al.*[52].

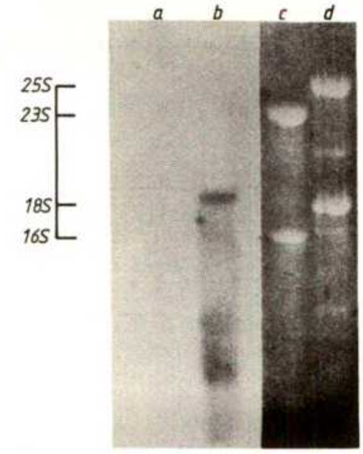

Fig. 4 Identification and sizing of legumin mRNA. Poly(A)$^+$ mRNA (1 μg) or total seed RNA (5 μg), prepared according to the methods of Hall *et al.*[53] and Girard[54], were denatured by glyoxylation and electrophoresed on 1.5% agarose gels by the method of McMaster and Carmichael[23]. The nucleic acids were transferred to nitrocellulose paper according to Thomas[24] and hybridized with ^{32}P-end-labelled or -nick-translated[28] cDNAs (specific activity 10^7 c.p.m. per μg). cDNAs were excised from the plasmids with *Bam*HI and separated on 0.5% agarose gels. The cDNAs were electroeluted from gel slices into dialysis tubing and recovered by alcohol precipitation. After end labelling or nick-translation, the cDNAs were re-electrophoresed through 0.5% agarose into dialysis tubing and used without alcohol precipitation for the hybridizations. Hybridizations were performed in the presence of 100 μg ml^{-1} polyadenylic acid to prevent nonspecific binding[44]. Autoradiographs of the hybridizations are shown as follows: track *a*, poly(A) mRNA from leaves; track *b*, poly(A) mRNA from developing seeds hybridized with ^{32}P-legumin cDNA (pRC 2.2.4). Tracks *c* and *d* show standard ribosomal RNAs, *E. coli* 16S and 23S, and pea 18S and 25S respectively, stained with acridine orange[23].

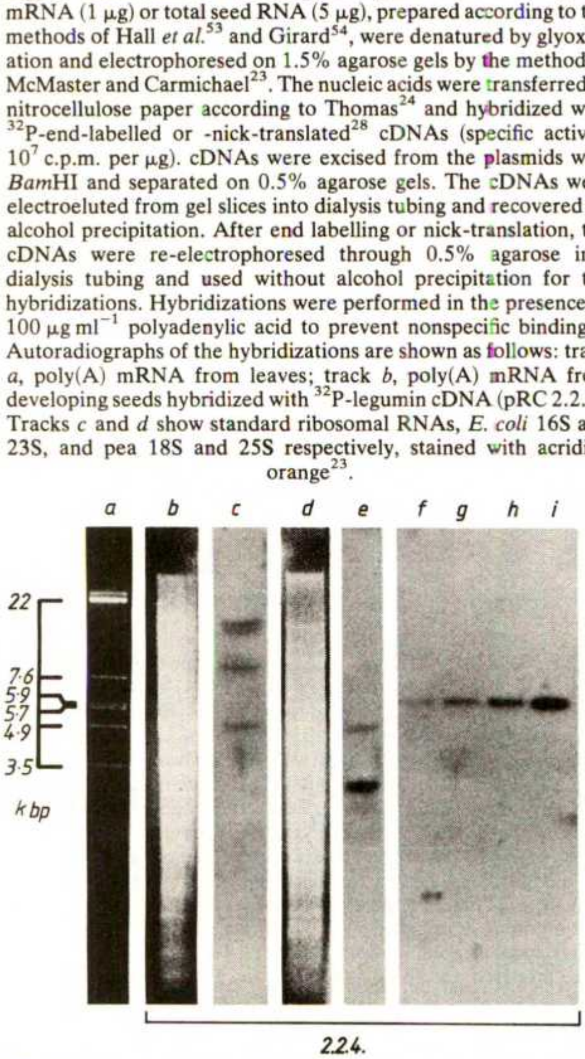

Fig. 5 Use of specific cDNAs to probe for legumin genes. Genomic DNA was isolated from developing pea leaves and purified twice on caesium chloride gradients[27]. Aliquots (5 μg) of the pure DNA were digested to completion with *Eco*RI, or *Hin*dIII. The fragments were then separated by electrophoresis overnight on 0.5% agarose gels and transferred to nitrocellulose paper[24]. The genomic blots were hybridized with ^{32}P-cDNAs prepared as described in Fig. 4 legend (specific activity $\geq 10^7$ c.p.m. per μg). Track *a* shows standard fragments of an *Eco*RI digest of λNM258, stained with ethidium bromide; tracks *b*, *c* show *Eco*RI and tracks *d*, *e* *Hin*dIII digests of pea genomic DNA stained with ethidium bromide (tracks *b*, *d*) and probed with ^{32}P-legumin cDNA (pRC 2.2.4) (tracks *c*, *e*); tracks *f*–*i* show 2.6, 5.3, 10.6, 26.5 pg of linearized plasmid pRC 2.2.4 (corresponding to 0.5, 1, 2 and 5 legumin gene copies in 5 μg of genomic DNA[27]) and hybridized with ^{32}P-legumin cDNA.

analyses and amino acid sequencing of purified acidic and basic polypeptides (refs 16, 31–33, 35 and Nielsen, personal communication)—that is, more than could be specified by four genes (for a review see ref. 36). Some of the additional heterogeneity may be accounted for by post-translational modifications[3,37] or, on the other hand, the probe used here may not have hybridized to all legumin DNA sequences. Similar analysis of genomic DNA isolated from pea seed cotyledons gave no evidence for selective amplification or alteration of the legumin genes in these tissues, supporting previous work[38].

The amino acid sequence deduced from the legumin cDNA nucleotide sequence clearly shows that the coding sequence for the acidic subunit precedes that of the basic subunit in the mRNA. The processing of legumin[1] seems to be analogous to that of animal insulin, where excision of a linking (C) peptide from the precursor proinsulin by proteolytic cleavage at Arg-Arg and Arg-Lys paired basic residues produces two disulphide-linked subunits[39,40]. Such adjacent basic residues have a prominent role as endopeptidase recognition sites in the processing of many animal polypeptide hormones and secretory proteins[21,40,41]. Although a similar linking peptide has not been demonstrated for the legumin precursor, examination of the deduced amino acid sequence upstream from the N terminus of the basic subunit reveals an unusually high content of the basic amino acids and the presence of an Arg-Arg sequence only five residues from the N-terminal amino acid. Although this may be a processing site, clearly further peptidolytic processing would be required to produce the N-terminal glycine. Similar 60,000-M_r legumin precursors have been demonstrated for *Vicia faba*[3] and *Glycine max* (unpublished results), suggesting a common processing mechanism.

The relatively long half life of the legumin precursors established by *in vivo* labelling[3,28] is in accordance with the above suggestions, and implicates a secondary membrane system distinct from the endoplasmic reticulum, such as the Golgi apparatus, in this processing. Harris[42] has suggested that the Golgi apparatus may be involved in the post-translational modifications and internal secretion of seed proteins, and it is known that the processing of proinsulin is carried out in this membrane system.

Results to be published elsewhere suggest that, like legumin, the vicilin polypeptide precursors[4,12] are synthesized only from high molecular weight mRNAs (17S) and these vicilin mRNAs are also derived from genes present in single or low copy number in the pea genome.

We thank Philippa Brown, Dave Bown and Ray Taylor for technical assistance, and Bill Brammar and Dick Flavell for their help and advice on cloning strategy. The financial support of the SRC is acknowledged.

Carboxyl–carboxylate interactions in proteins

Lindsay Sawyer* & Michael N. G. James†

MRC Group in Protein Structure and Function, Department of Biochemistry, University of Alberta, Edmonton, Alberta, Canada T6G 2H7

Much of our present understanding of macromolecular architecture has come from the extrapolation to large molecules of rules derived from analysis of small molecules. This is exemplified by the work of Pauling *et al.*[1] on polypeptide conformation, which depended on the insight afforded by the crystal structures of individual amino acids and some dipeptides. Now that accurate protein crystal structures are available, it appears that most of the hydrogen-bonding patterns that are observed have already been found in the structures of small molecules. Thus we can learn much about weak interactions in proteins by analysing small molecule crystal structures. Here we comment on the existence of hydrogen bonds between two carboxyl groups, forming what amounts to the acid salts of monobasic carboxylic acids. We believe these interactions are more important in stabilizing the structures of protein crystals and multi-subunit complexes at low *p*H than has been realized previously. Furthermore, the interaction contributes to hydrolytic activity and may be involved in inter-subunit recognition.

Speakman[2] has described type A and B monobasic acid salts of general formula MHX_2. Examples of type B, having the formula $M^+X^-.HX$, rubidium hydrogen bisglycollate hydrate[3] and potassium hydrogen di-*p*-nitrobenzoate[4]. On the other hand, type A salts have formally equivalent X units requiring the O...H...O bond to be situated on a symmetry element. For example, the carboxyl groups in the crystals of potassium hydrogen bisphenyl acetate are related by a centre of symmetry[5] and, of more interest here, sodium hydrogen diacetate has a dyad axis relating the acidic groups[6]. Only one proton is involved in the interaction so that the carboxyl groups adopt an offset arrangement which allows a variety of conformations. We have defined these conformations in terms of five angles and the distance of the hydrogen bond (see Table 1). The remaining negative charge in the case of the small molecule is balanced by a nearby cation, M. The structures of many such acid salts have been reported and it is not surprising to find that they exist in proteins. Table 1 shows some typical carboxyl group dimensions for these salts.

'Pronase', a crude extract from cultures of *Streptomyces griseus*, contains several distinct proteolytic enzymes, of which the crystal structures of protease A (SGPA) and protease B (SGPB) have been refined at high resolution. Each has a distinctive carboxyl–carboxylate hydrogen bond as an essential intermolecular interaction. SGPB crystallizes in space group $P2_12_12$ from 1.2 M KH_2PO_4, *p*H 4.2 (ref. 7). Refinement has given an *R* factor of 14.9% for the data to 1.7 Å. From Fig. 1*a*, which shows the region around the crystallographic dyad, it can be seen that the Glu 137 residues (192A) form a close interaction. (Numbers in parentheses refer to alternative numbering schemes[9,10].) This relationship is precisely that found in type A acid salts and the separation is consistent with a very short hydrogen bond (see Table 1). Note that there is no balancing cation as observed in the small molecule structures. O255 could perhaps be considered a cation but the occupancy and temperature factor would be consistent only with H_3O^+. However, in every case where an oxonium ion has been examined in a crystal, there is a pyramidal arrangement with three hydrogen bonds of ~2.6 Å (ref. 8). The hydrogen bond from Glu 137 O^ϵ (192A) to Cys 162 N (220) will partly counteract the extra negative charge because of the peptide dipole. At *p*H ~4, partial protonation of a glutamic acid side chain (pK_a = ~4.3) is expected. Removal of

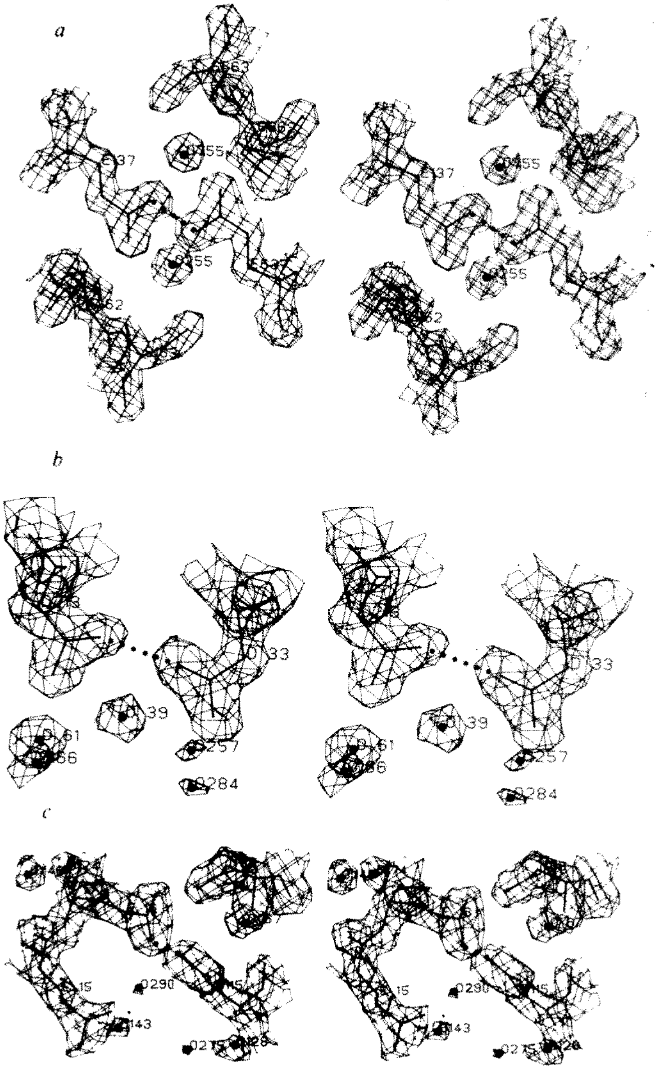

Fig. 1 The carboxyl–carboxylate interactions in *S. griseus* protease B and penicillipepsin. In each case, the hydrogen bond is shown as a dotted line but for clarity the other hydrogen bonds have been omitted. *a*, Type A interaction in SGPB viewed in the direction of the dyad axis parallel to *c*. The contour level is 0.6 e $Å^{-3}$. For ease of identification the residues of the twofold-related molecule have had 500 added to their sequence numbers. *b*, Type B interaction of the two catalytic residues in penicillopepsin, Asp 33(32) and Asp 213(215). The contour level is 0.5 e $Å^{-3}$. *c*, The second type B interaction in penicillopepsin involves Asp 115(114) and Glu 16(13). The contour level is 0.45 e $Å^{-3}$.

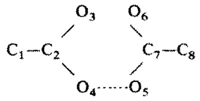
Table 1 Distances and angles for carboxyl–carboxylate interactions

Compound	κ_1	κ_2	κ_3	κ_4	κ_5	d (Å)	Type
Rubidium bisglycolate hydrate	172.6	172.6	57.0	115.7	120.6	2.53	B
Potassium hydrogen di-*p*-nitrobenzoate	175.5	149.0	81.3	109.7	140.4	2.49	B
Potassium hydrogen bisphenyl acetate	177.7	180.0	177.7	113.9	113.9	2.44	A
Sodium hydrogen diacetate	166.8	137.7	166.8	110.8	110.8	2.45	A
Imidazolium hydrogen maleate*	49.8	38.7	49.6	109.6	109.2	2.37	A
SGPA	168.2	130.9	54.9	118.5	116.1	2.51	B
SGPB	173.0	159.5	173.0	112.5	112.5	2.49	A
Penicillopepsin Asp 33–Asp 213	123.8	149.8	147.1	159.0	147.4	2.88	B
Penicillopepsin Glu 16–Asp 115	168.4	134.1	163.7	123.1	113.0	2.75	B
Actinidin†	168.6	174.8	168.0	124.5	119.5	2.51	B

The angles are defined with respect to the carboxyl groups assigned, for type B acid salts, such that subscript numbers 1–4 refer to the —COOH and, for proteins, to the group of lower sequence number.



Torsional angles: κ_1, C_1C_2–O_4O_5; κ_2, C_2O_4–O_5C_7; κ_3, O_4O_5–C_7C_8. Bond angles: κ_4, $C_2\hat{O}_4O_5$; κ_5, $O_4\hat{O}_5C_7$. Distance: d, O_4–O_5. Angles are measured in degrees. Standard deviations for the small molecule structures are of the order of 0.01 Å for bond length, 0.1° for bond angle and 0.2° for torsion angle. For the protein structures, the corresponding values are ~0.1 Å, 3.0° and 5.5°. Type A salts exhibit very short, apparently symmetrical hydrogen bonds typified by[22] OH stretching frequency in the 700–1,000 cm^{-1} region and bond strength of ~8 kcal mol^{-1}. * Ref. 21. † Ref. 16.

the proton by raising the *p*H leads to repulsion of the two negative charges, which in turn destabilizes the crystals and at *p*H values >4.5, both SGPB and SGPA crystals dissolve. In a paper describing the refinement of SGPA, Seilecki *et al.*[11] present the interaction between the carboxyl group of Asp 123 and the terminal carboxyl group of Leu 242. This hydrogen-bonded interaction is of type B and includes a charge neutralizing Na^+. The two carboxyl groups arise from separate molecules and thus contribute to the stability of the crystal structure. Parameters for this interaction are also included in Table 1.

The crystal structure of the aspartyl protease, penicillopepsin[12], has recently been refined at 1.8 Å resolution to an *R* factor of 13.6% (to be published). The carboxyl groups of the two catalytic aspartyl residues, Asp 33(32) and Asp 213(215), also share a proton at *p*H 4.4, the *p*H of the native crystals. These carboxyl groups are at the junction of the two large domains of the aspartyl proteases, at the bottom of the substrate-binding cleft. Their spatial arrangement is different from the examples given above (see Fig. 1*b*). As in SGPB, there is no balancing cation for the type B acid salt in penicillopepsin. However, the excess negative charge is in part balanced by the proximity of several peptide dipoles[13]. The carboxyl groups are also arranged so as to provide an electrophilic proton as well as to help stabilize the inter-domain junction. Furthermore, pepsin is reported[14] to have a slightly raised pK_a for Asp 215(213) which is as expected where two carboxyl groups are maintained in close contact. That such a juxtaposition can cause an unfavourable interaction is seen in the structure of *Rhizopus chinensis* pepsin, where the homologous aspartyl residues adopt a totally different disposition to relieve the repulsion evident at *p*H 6.5 (ref. 15).

A further example of this is found in penicillopepsin (Fig. 1*c*), where the juxtaposition of the carboxylate of Asp 115(114) with that of Glu 16(13) demands that they share a proton, but the torsion angles (see Table 1) in this case seem more in keeping with a type A structure, although the small molecule data may not be representative. This seems to be associated with the additional presence of a hydrogen-bonding amide group from Asn 118(117) which donates the proton from Asn 118 $N^{\delta2}$ to the other oxygen $O^{\epsilon1}$ of Glu 16 ($d = 2.91$ Å). It can be seen that the carboxyl group of Glu 15 is not involved directly with these interactions.

The values of torsion angles κ_1–κ_3, bond angles κ_4 and κ_5, and bond length d, for the proteins examined are not unusual when compared with those of the acid salts (Table 1). However, the values of κ_4, κ_5 for the Asp 33(32)–Asp 213(215) interaction in penicillopepsin are appreciably higher and the distance separating the oxygen atoms is slightly longer than in the other examples. This is consistent with the less than ideal arrangement of proton sharing expected if the proton is to take part in catalysis.

The imposition of a restricting, near-neighbour arrangement for two carboxyl groups can lead to an anomalous pK_a. Thus, the *cis*-double bond of maleic acid leads to the high pK_{a2} of 6.1 as compared to that of 4.4 for the *trans*-isomer, fumaric acid. In proteins it seems unlikely that an anomalous pK_a may arise from an analogous restrained environment around two carboxyl groups. Unfortunately the unambiguous assignment of anomalous titration data to particular carboxyls in proteins does not coincide with the highly refined structures available. For example, the actinidin structure at *p*H 5.9 (ref. 16) shows a type B acid salt interaction between glutamic acid residues 50 and 86 but no titration data are available. In the case of tobacco mosaic virus there is ample evidence for anomalous carboxyl groups[17,18] but their interactions, although almost certainly of the type we describe, are not yet known in sufficient detail[19,20].

We may conclude that the carboxyl–carboxylate interaction is an important stabilizing force in protein–protein interactions at low *p*H and, at higher values, may occur more frequently than previously believed in association with an anomalous pK_a. Conversely, the unambiguous detection of an anomalous pK_a for acidic groups in proteins can be, and often is, a sign of carboxyl–carboxylate interactions of the type described here.

We thank W. Anderson for helpful criticism and C. Broughton, C. McPhalen and A. Sielecki for valuable assistance. L.S. thanks the MRC (Canada) for a Visiting Scientist Award and Lothian Regional Council for leave of absence. This work was supported by a MRC (Canada) grant to the Group on Protein Structure and Function, University of Alberta.

BOOK REVIEWS

Nationalized science and technology

Eric Ashby

THIS is a sober and sobering book. Professor Tisdell was asked "to prepare an independent background report on the subject of priority assessment in science and technology for the Australian Science and Technology Council". His book is an expansion of this report. Don't assume that it is of interest only to Australians; the prospects for Britain might be less depressing if a number of senior civil servants and members of the present government were to be given three days' leave in order to read the book and ponder its message.

When Queen Victoria came to the throne the pursuit of science, like the pursuit of literature, was a career for the self-employed, often subsidized by payment from some other occupation. T.H. Huxley earned his living at first by teaching; Anthony Trollope by inspecting post-offices. The notion that there was need for a science policy would have been as crazy as the notion that there was a need for a policy among poets and novelists.

By the time Queen Elizabeth came to the throne all this had changed. Poets and novelists could still pursue their stars without deviations caused by governments, but scientists were no longer immune from influence. The critical time was the year when the government grant to universities exceeded 50 per cent of their total income. There was no *dirigisme* at first, of course. The taxpayer had become paymaster and patron of science but initiative was left, still, to individuals. But the seeds of *dirigisme* had been sown. We are now painfully reaping the harvest: a rank growth of policy-documents, technology assessment, predictions about research and development. The public interest is now called a "customer" and the laboratory worker a "contractor": science by mail order.

This is, of course, the inevitable result of the staggering successes of science applied to human needs (though in one sense it would be more accurate to say science applied to human destruction). Governments have realized that research and development is too important to be left to industry alone. More and more scientific research — both pure and applied — is now the "property" of the taxpayer, whose money pays for government research establishments, the grants from research councils and a great deal of the costs of universities. The scientist, provided he is willing to work on problems for which he can get grants, can adapt himself to this situation. It is the customer who is in a dilemma. He has to draw up a shopping list and he hasn't enough money to pay for all the science he would like to have. So he has to decide priorities. And since "he", in a pluralistic democracy, is the social welfare function — the consensus of society — the task of deciding priorities is, on rational criteria, insuperable. The best one can do is to make provisional choices on imperfect evidence.

Science and Technology Policy: Priorities of Governments. By C.A. Tisdell. Pp.222. ISBN 0-412-23320-7. (Chapman and Hall: 1981.) £12, $25.

Tisdell's book is a manual of advice for those who make such choices. His starting points are the lists of research and development objectives published by OECD and the EEC. They are taxonomic lists of no great value. He then discusses an issue of special relevance to countries with small economies (compared with the giants), namely how much science should such countries import and exploit? And to what extent should such countries rely on their own springs of initiative in pure research? There is, he explains, a trade-off between the import of ideas and their local production. The profit to be made out of the exploitation of a new idea will vanish as soon as some (so called) less developed country starts marketing it at a fraction of the manufacturing cost.

The bulk of Tisdell's book is taken up with an analysis, well documented and supported by quantitative data, of the research and development policies of large economies (Germany, Japan, Britain and the USA) and small economies in the OECD (Belgium, Canada, Netherlands, Sweden and Switzerland). In all of these countries there is some formal procedure for setting priorities, sometimes well co-ordinated, sometimes (notably in Britain) fragmented among different government departments. For a while these procedures were conducted by bureaucrats and experts without reference to the public and without canvassing public opinion. This, as Tisdell demonstrates, is no longer practicable or desirable. Not only does the public want to participate through public interest groups — that is proving difficult enough — but also there are surges of pressure to change the order of priorities. Thus in the 1950s the assumption was to use profit and market success as the units for assessing research and development. Then in the 1970s the assumption was challenged; improvement of the quality of life rose higher in the shopping list. Now we are back again to less exalted objectives: in a world depression, the high priority is to survive economically by capturing markets, and this has come to be the short-term aim of research and development.

In a sombre last chapter, Tisdell asks the questions — though of course he cannot supply the answers — that spin round in the policy-maker's mind all the time. Everyone admits that the optimum social welfare function cannot be derived from individual welfare functions; no one has a *politically* practicable alternative except to bring to politics the techniques of the oriental marketplace: haggling, trade-off and bluff. Not everyone, but many thoughtful people, admit that high unemployment among untrained people is a consequence of much modern technology; no one has a remedy for this evil except to repeat platitudes about making education more relevant (hardly a practicable proposal for schools on their present starvation diet).

At one point Tisdell suggests three options open to governments for science and technology: to try to slow down the rate of change; to let change proceed unplanned, in which individual governments and industries pursue their own self interest "with scant regard to the common good"; to establish collective or social priorities (and, I would add, international priorities) for the programme of change in science and technology. The first of these options is as feasible as stemming the tide; the second is an open cheque for chaos; the third is the only tolerable option. But will a nation as pluralistic as the United States, or as socially polarized as Britain is these days, adopt this option? President Carter's call for austerity to cope with "the moral equivalent of war" didn't meet with much response; Britain's attitude to the Brandt Report hasn't provoked a surge of altruism. The question, often asked and not yet answered, is whether human communities can make painful adaptations to avoid a breakdown in economic order before it comes; or whether, like communities of animals and plants, the adaptations will follow only as a response to a harsh environment after its effects have begun to bite. It is a sign of his anxiety that Tisdell turns at the end of his book to Daniel Bell's ominous book on the post-industrial society, with its "lack of an ordering mechanism to make social choices". Tisdell warns: "We may all know that collectively we are heading for tragedy but individual self-interest of nations and of individuals may necessitate the tragedy to be played out". In a sensational pamphlet on doom such a sentence as this might be shrugged off. In an economist's sober report to the Australian Science and Technology Council, the sentence has a ring of integrity and conviction; for Tisdell offers an antidote to despair: "A fall in exports and in living standards *could* be worthwhile from the point of view of achieving more basic ends". ☐

Lord Ashby was formerly Master of Clare College, Cambridge. His most recent book, written with Mary Anderson, is The Politics of Clean Air *(Clarendon/Oxford University Press, 1981.)*

From myth to methodology

C.K. Brain

Bones: Ancient Men and Modern Myths. By Lewis R. Binford. Pp.320. ISBN 0-12-100035-4. (Academic: 1981.) £24.20, $36.50.

IT IS perhaps surprising that a new book by one of the most influential of archaeologists should deal, not with cultural remains, but with bones. By way of explanation, Lewis Binford observes that almost all of our ideas on the behaviour of prehistoric men have been based on interpretations of faunal remains and their depositional context — not, as so many textbooks would lead one to believe, of stone tools. So, in discussing reconstructions based on bones, Binford has significant things to say about the proper conduct of scientific enquiry as well as about the behaviour of early man.

Most of the inferences that have been drawn about the nature and activities of our prehistoric ancestors are seen by Binford as little more than "myths of prominent men". Some of these concepts may well have been accurate, but unless they were the products of a robust and reliable methodology for giving meaning to bones, they remain myths based on the opinions and perhaps even the biases of the investigating archaeologists. In traditional archaeology, Binford believes that concepts about early man have often been judged in accordance with the status of the archaeologist who propounded them. "We desperately need to abandon the technique of evaluating men and adopt the strategy of evaluating ideas", he writes, for in the absence of methodology it is people's reputations that are reshuffled.

The kind of methodology proposed by Binford as an alternative to myth-making is embodied in what he calls "middle-range research". A crucial characteristic of theories resulting from such research is that they are intellectually independent of the arguments about the phenomena they are used to illuminate. As an example, Binford cites the case of carbon-14 analysis, where independent physical research had established a reliable body of theory about the relationships between living organisms, atmospheric ^{14}C and rates of degeneration of the radioactive isotope. Such relationships have been put to good use by archaeologists wishing to date organic remains preserved at their sites.

Apart from philosophical considerations of myths and methodologies, the main aim of the book is to provide a set of objective criteria for the recognition of human influence in the accumulation of a bone assemblage. What are the characteristic patterns of bone modification produced by non-human agents and how can these be distinguished from human modes of bone alteration? In attempting to answer these questions, Binford has drawn on his own extensive observations of Nunamiut Eskimos and their dogs in Alaska, as well as of wolves that inhabit those parts. He has provided a wide-ranging review of relevant work done elsewhere and has set up a convincing array of diagnostic criteria for separating hominid- from non-hominid-built bone accumulations.

Finally, in the third part of the book, Binford applies his methodology to bone assemblages from Olduvai Gorge, making use of data provided by Mary Leakey in Vol. 3 of *Olduvai Gorge.* As Clark Howell has pointed out in the foreword to Binford's book, these data were not collected for this specific purpose and so are not ideal. Nevertheless, some bold conclusions have been reached by Binford, such as that there is no evidence that Olduvai hominids hunted, or that they made use of base camps to which food was carried to be shared. Instead, our hominid ancestors are seen as having been scavengers at discarded carnivore kills where hammerstones were used to break open leg bones to extract marrow.

Binford's book is a major, if controversial, contribution to the rapidly expanding literature on the new science of taphonomy. Already his conclusions are being challenged, for example by H.T. Bunn (*Nature* **291**, 574–577), and it will be interesting to follow the fortunes of his ideas under the impact of the rigorous methodology that he so eloquently advocates. ☐

Nature's plumbing

Philip England

Geysers and Geothermal Energy. By John S. Rinehart. Pp. 223. ISBN 3-540-90489-1. (Springer-Verlag: 1981.) $22.50, DM 38. *Geothermal Resources: An Energy Alternative.* By Harsh K. Gupta. Pp. 227. ISBN 0-444-41865-2. (Elsevier Scientific: 1981.) $61, Dfl. 125. *Geothermal Systems: Principles and Case Histories.* Edited by L. Rybach and L.J.P. Muffler. Pp. 359. ISBN 0-471-27811-4. (Wiley: 1981.) £22, $52.25. *Geothermal Systems.* By John Elder. Pp. 508. ISBN 0-12-236450-3. (Academic: 1981.) £20.60, $49.50.

STATED simply, a geyser is a water system to which mass and/or heat are added until a portion of the column is super-critical. At some stage nucleation of boiling occurs in this region and the consequent expansion partially empties the water column, reducing the pressure within it and leading to further boiling in the decompressed system, with spectacular eruptions of steam and water at the surface. The diversity of style and periodicity of geyser eruptions results from the almost endless variations on this theme which are possible given the multiple recharge–discharge systems occurring in nature.

In *Geysers and Geothermal Energy* John Rinehart has provided a detailed — one might say an affectionate — catalogue of these idiosyncrasies, together with the complex hydrological interpretations of them, when available. He also discusses briefly the geochemical and environmental aspects of geysers. One disappointing aspect of the book is that not enough attention is paid to the central process of geyser eruption: the problems of boiling initiation and bubble nucleation are dealt with in a cursory fashion. In other respects the book provides all the information on geysers that the layman or student could reasonably ask for. There is, in addition, one chapter of 15 pages on geothermal energy.

The remaining three books reviewed here all approach geothermal systems by way of an outline of plate tectonic theory, mantle convection and the present distribution of tectonic activity, and then diverge along lines that are to be expected from their formats. Gupta's *Geothermal Resources* is one of Elsevier's series on Developments in Economic Geology, and attempts to cover every aspect of the subject at the expense of the brevity which a 200-page format imposes on such an approach. The book is a review of the subject, covering everything from Earth structure and the basics of heat transfer (although convection is treated solely in terms of Newton's law of cooling) to production technology and world energy problems. The level and quality, however, are considerably lower than either of the two remaining books. The section on global dynamics is not good, and nothing is dealt with in adequate detail. Further, the material is not particularly up-to-date and for a book of its price and brevity it has been poorly edited.

Geothermal Systems: Principles and Case Histories, a collection of papers edited by Rybach and Muffler, concentrates on specific topics. Following an introduction on geothermal anomalies and global tectonics, there are contributions on heat and mass transfer in hydrothermal systems, geothermal prospecting, heat extraction from reservoirs and resource assessment and environmental aspects, on which lucid and informative reviews (with up-to-date references) have been provided by people active in these particular fields. The reviews fill two-thirds of the book, the remainder consisting of case histories from various geothermal fields. These latter papers provide roughly the same sequence of information — geological framework, history of exploration, present-day exploitation — but are of a more variable quality than the first part of the book. The areas covered are the low enthalpy resource of the Pannonian Basin, the use of steam for electrical power generation from the Krafla field in Iceland, the Takinoue field in Japan and the Ahuachapan field in El Salvador, and the Jemez geothermal field — which contains high- and low-temperature hydrothermal systems as well as hot dry rocks. The book concentrates on the geological and geophysical aspects of geothermal energy extraction, so that there is little information on the engineering problems or the economics of this source of power.

To a greater extent than is usual for a collection of papers, this volume does succeed in giving a coherent picture of the subject. Credit for this must go to the editors who have chosen judiciously the areas to concentrate on and, I suspect, exerted some unifying influence on the contributions in the last one-third of the book.

If the antipodean reader were to feel that the geothermal fields of New Zealand are given unduly little attention in Rybach and Muffler's book, this hole is firmly plugged in Elder's volume of the same title. The book ought more properly to be called *Hydrothermal Systems*, as the possibility of extracting heat from dry rocks is not addressed. Instead, Elder provides a comprehensive survey of the mechanisms of heat and mass transfer within the Earth, at a higher level, but in a style which will be familiar to readers of the *Bowels of the Earth*. I am not referring to the use of anatomical analogies; that aspect is, mercifully, absent from the book (one may imagine the emunctory analogues which could be produced for hydrothermal systems).

The approach Elder adopts is more that of the engineer than of the applied mathematician or physicist; as he explains in the preface, this arises from a natural desire to avoid deducing from first principles a set of results that are inconsistent with our observations of the Earth. It leads him to produce models for each system that he investigates which are characterized by pragmatism and simplicity, and which permit him to estimate order-of-magnitude figures for everything from global partial melting to the motion of steam bubbles in mud. Such an approach can be extremely successful (more so with bubbles than partial melt) but depends on the amount of common ground one shares with Professor Elder; certainly, it beats deriving every aspect of water–rock interaction from the Second Law of Thermodynamics, but it can be carried too far. After 400 pages of models being pulled out of whichever hat Professor Elder is wearing, either one suspends critical faculties and accepts each model at face value (rather than working out the extent to which it matches geological reality), or one starts to feel the need for a more explicit physical base to what is being said. This is more of an error of judgement than a major drawback and there is much to gain from such a refreshing approach to the subject.

My only other criticism is of a similar order: the first 160 pages of this book are devoted to global tectonics and the origin and emplacement of magma bodies: aside from the fact that a newcomer to the subject would gain from it an impression that no geophysicist or geologist has worked on these problems, this is surely an over-long introduction. ☐

Ecology: a Japanese perspective

John Lawton

Comparative Ecology, 2nd Edn. By Y. Itô. Edited by Jiro Kikkawa. Pp. 436. ISBN hbk 0-521-22977-4; ISBN pbk 0-521-29845-8. (Cambridge University Press: 1981.) Hbk £22.50, $54; pbk £9.95, $19.95.

SCIENCE, like pop music or *haute couture* has fads and cliques, although scientists like to pretend otherwise. Ecology is no exception, with too many groups isolated to a greater or lesser extent by language, geography, tradition and the impossibility of reading even a fraction of the relevant literature. Contact between European, North American and Japanese ecologists has generally been good, but inevitably many papers in Japanese go unread by English-speaking scientists. A major strength of Professor Itô's book is to summarize and publicize work originally published in Japanese — roughly ten per cent of the entries in the long and comprehensive bibliography are in this category.

That said, I have to admit that I found the book heavy going, not because of Jiro Kikkawa's excellent translation, but because of the almost overwhelming mass of detail which Itô compresses between the covers, organized around a single unifying, but in the end not wholly convincing, theme.

For Itô, the animal kingdom is divided into beasts of the two sorts. On the one hand are those opting for high fecundity, living in environments where food for their young is easily procured; and on the other are species whose young enter a more hostile world, displaying low fecundity and parental care as a consequence. The whole of population dynamics, territorial behaviour and animal society are then interpreted within this simple framework.

Itô is at pains to show how his world view differs from the deeply entrenched traditions of "r and K selection" more familiar to European and North American ecologists. Certainly there are differences, albeit rather subtle. More importantly, Itô's view stands or falls on his ability to provide an independent measure of food supply. On this fundamental point his thesis is distinctly shaky. Food supplies are never measured directly; indeed his logic is often

Circle No. 12 on Reader Enquiry Card.

circular — if an animal displays parental care, its young, by definition, face an impoverished habitat.

To be fair, I suspect that Itô hopes to provoke others into making the necessary measurements, and like all attempts to force the bewildering variety of the living world into a manageable framework, his vision is certainly true in parts. Thus high, or low, fecundities (Chapter 1) do tend to be associated with particular types of survivorship curves (Chapter 2), generating particular patterns of population fluctuations (Chapter 3), and social systems (Chapters 4–6). But there are bound to be numerous exceptions, and in trying to force every example into one mould, the book sometimes makes difficult reading.

European and North American colleagues will also feel uneasy with those parts of the book which fail to incorporate important concepts from their own contemporary literature. I noticed this particularly in Chapter 3, which deals with population fluctuations in a way that fails to reflect major advances of recent years.

I make these criticisms very reluctantly, because any book which increases the flow of ideas and information between groups of ecologists is to be welcomed. Nonetheless it must be said that this is not a good book to use with undergraduates, despite the fact that they may be more receptive to new ideas than teachers! But I do think that anybody interested in animal population dynamics and social behaviour should look at it, particularly for the richness and relative unfamiliarity of many of its principal characters. □

John Lawton is a Senior Lecturer in Ecology in the Department of Biology, University of York.

The inconstant biological membrane

A. Silberberg

Mechanics and Thermodynamics of Biomembranes. By E.A. Evans and R. Skalak. Pp.272. ISBN 0-8493-0127-0. (CRC Press/ Blackwell Scientific: 1981.) $34.95, £26.

MOST material systems are not mechanically simple. The stresses which arise cannot be expressed by the one- or two-parameter relationships which, nevertheless, have scored enormous practical successes. Much of fluid mechanics is based on the Navier–Stokes equations for an incompressible Newtonian fluid, and much of solid state deformation theory on a loss-less, purely elastic material constitutive equation.

The science of rheology has tended to bridge this gap in the engineering world, but in biology such complications are still mostly avoided. This is particularly reprehensible when, as is natural with living systems, movement of components, and indeed chemical reactions, have to be considered alongside any description of the stresses and strains which shape and confine the structural components. In developing the analysis of the chemical potential gradients along which transport of the various distinguishable chemical species will occur, the mechanical contribution is generally represented by a hydrostatic pressure gradient at most. Structural elements are taken out of consideration by being thought of as chemically inert and mechanically rigid.

This book by Evans and Skalak is thus a most welcome newcomer. It contains four main sections which, following an introduction, cover the kinematics, the dynamics and the thermodynamics of membranes; the final section summarizes the experimental situation. Some 100 references are given and a good index is also provided. The authors deal specifically with those membranes which confine cells or sub-cellular compartments, discussing the factors which mechanically govern the shape and thermodynamically will influence the stability of these systems.

This is, to my knowledge, the first systematic attempt to develop the considerations basic to the field in textbook form. The book is thus highly recommended to all workers in physiology and biophysics — to all scientists, in fact, who are dealing with the mechanics and thermodynamics of the interface in systems of heterogeneous and complex structure.

A. Silberberg is the Joseph and Marian Robbins Professor of Biorheology in the Department of Polymer Research, The Weizmann Institute, Rehovoth, Israel.

Electron microscopy

- A new volume in the series *Practical Methods in Electron Microscopy*, edited by Audrey Glauert, has recently been published by Elsevier/North-Holland Biomedical Press. Volume 9, *Dynamic Experiments in the Electron Microscope* by E.P. Butler and K.F. Hale, deals with the study of the response of materials to a change in state, using the transmission electron microscope, and costs hbk Dfl.195, $95; pbk Dfl.92, $45.
- M.A. Hayat's *Principles and Techniques of Electron Microscopy: Biological Applications* has now appeared in a second edition. Like its predecessor, the aim of the new edition is to provide a foundation in the biochemical concepts underlying the preparation of specimens for transmission electron microscopy. Co-published by University Park Press and Edward Arnold, the book costs $34.50, £27.50.

MeV volume

M.H. Key

Laser Interaction and Related Plasma Phenomena, Vol.5. Edited by Helmut J. Schwarz *et al.* Pp.850. ISBN 0-306-40545-8. (Plenum: 1981.) $75, £47.25.

LASER plasma interactions at high levels of irradiance involve a fascinating variety of physical processes and phenomena. Plasma produced in this way has many significant applications, arising mainly from the extreme energy density available. Laser fusion is the major motivation of much of the world-wide activity, but basic physics investigations — for example into X-ray lasers, energy transport in high temperature gradients and the characteristics of matter at extreme pressures — are beneficiaries of the technical developments arising from laser fusion research.

It is difficult to produce books which adequately describe the state of the art in such a wide-ranging and fast-moving field. The well-tried formula of a compilation of contributions from specialist authors has the best possibilities and the present volume is the latest in a series of this genre.

The old editorial team of H.J. Schwarz and H. Hora has been strengthened by M.J. Lubin and B. Yaakobi of the University of Rochester, and the book presents contributions from an internationally representative panel of 37 scientists who lectured at a workshop in 1979. I find that the book provides a better-organized selection of material than some of the earlier volumes; it has a mix of basic reviews and current research topics, and therefore offers something both for those researching in the same field and for those with a more general interest.

There are five major sections, covering lasers and alternative pulsed power sources, interaction experiments, general considerations for fusion, fusion-related experiments and interaction theory, and here the reader is given a fairly good guide to the topical issues of 1979–1980. The review material covers subjects such as new lasers, free electron lasers, light ion beams, new fusion fuels, high-density diagnostics, target manufacture, soliton theory, Rayleigh–Taylor instability, stimulated scattering and Stark broadening of high Z ion lines. It is generally authoritative and up to date. The descriptions of more detailed research activities have inevitably become somewhat dated, though specialists will find them useful as sources of reference to past work.

I feel researchers in the field will want access to this book as a valuable compendium of information, while non-specialists may wish to consult one or more of its review sections. □

M.H. Key is Deputy Head of the Laser Division at the SERC Central Laser Facility, Chilton, Oxfordshire.

Creationists and science in schools

Creation science has rightly been denied a licence in Arkansas on the grounds that it is religion in disguise. The educational implications are even more sinister.

The creationists may have lost the battle in Arkansas, but they are unlikely now to abandon the war on which they are engaged. Science educators everywhere, but especially in the South, had better reconcile themselves to that. The United States courts are notoriously a means by which determined if misguided people can refuse to accept the inevitable, creating confusion and widespread nuisance. In the circumstances, it is important that everybody should be clear what the war is about. It is not a war about the validity of Darwinism, however understood and glossed. Nor is it a war between religion and science, for some of the most influential evidence against the creationists in Judge William Overton's court came from religious people anxious to dissociate themselves from the claims of the creationists. The underlying dispute is between a small section of the religious community in the United States to whom the evolutionary view of the world, inanimate and living, is anathema. The claim that "creation science" should be taught alongside orthodox evolution as if it, too, were science is both preposterous and disingenuous.

The richest irony in the creationists' case is the attention that it pays to the supposed flaw in Darwinism, which is alleged to be unfalsifiable experimentally. By what logic can it be held that because Darwinism is unfalsifiable in some technical (and disputed) sense, a set of hypotheses which is in the same sense falsifiable and amply falsified should be given equal time in the curriculum of the public schools of Arkansas and elsewhere? How, in the side-by-side science lessons for which they have been asking, would the creationists deal with questions such as the presence in the Earth's crust of lead isotopes which have apparently accumulated over the past 4,500 million years? By asserting that the technically falsifiable but amply verified explanation of radioactive decay is also false? And in that case, why should the proportions of radiogenic and nonradiogenic lead have been created at some later time in such a way as to mimic the effects of geochemical differentiation? To fool us? Or to show that the Creator was a good geophysicist? Most religious people rightly and consistently dismiss such questions as irrelevant, and and even sacrilegious.

Other educational questions remain. Although the chief basis of Judge Overton's decision was that the state law he struck down was unconstitutional by providing a disguise for religious teaching, in many ways its requirements of science teachers were a more sinister threat to good sense. For teachers who are not allowed to tell what they consider to be the truth and who are required to tell lies are necessarily bad teachers. How are these epitomes of duplicity to be trained? Or is it thought, in Arkansas and elsewhere, that the teaching of science consists of the recitation of facts by teachers and feats of memory by students? Legally, what Arkansas had planned to ask of its teachers was an offence against the First Amendment. The damage that Arkansas had unthinkingly proposed inflicting on the education of its young people would have cast a longer shadow. When the issue of creationism in the schools comes up next, in Louisiana or wherever, the educational folly of giving equal time and place to a literal interpretation of *Genesis* should be given as much attention as its consitutional impropriety.

At the same time, some thought should be given to the way in which an over-literal interpretation of the constitutional interdiction against religious teaching in the public schools is itself an impoverishment of American education. *Genesis* may be a pack of lies, or of allegories, but it is also an important part of the cultural heritage. So, too, is the Koran. Is it necessary that these important topics should be forever ignored, or relegated to "Eng Lit." or fuzzy courses such as "the world about us" simply because school boards fear they may be accused of propagating religious views? For that matter, should the history of the world outside the Americas continue to be considered suitable only for colleges and universities? It is unlikely that the creationists now pushing for creation science would be mollified by concessions along these lines. But school boards throughout the United States should not think that Judge Overton's judgement is an all-round endorsement of the present curriculum.

Selling off telephones

Settlement of the anti-trust suit against AT&T will change the company — and the world

The Justice Department in the United States has followed the only sensible course by agreeing to stop its long-standing action against the world's largest company, American Telephone & Telegraph Company (AT&T). The basis of the complaint, that the dominant telephone company in the United States has used its profits from one kind of service (long-distance telephone calls for example) to subsidize other services (local telephone services) has in any case been overtaken by events. In a long succession of decisions in the past decade, the Federal Communications Commission has balanced a relaxation of the rules restricting regulated telephone companies (such as AT&T) from entering unregulated business (such as data transmission) with increasingly explicit rules against cross-subsidies. If the judgement in the suit had gone against the company, it would have seemed a nonsense in present circumstances — and would have left unresolved the question of what, in any case, should happen to AT&T. Only the lawyers would have profited.

So does last week's settlement presage the most radical transformation of American industry since Standard Oil of New Jersey was broken up in 1911? Not necessarily. AT&T has undertaken to sell off its interests in those local and regional telephone companies across the United States which at present deal directly with local customers. It will retain its long-distance network and will also win the right to compete directly with other companies in the telecommunications business, both domestically and overseas. Perhaps more important in the long run, the company will retain control of the Bell Laboratories (and of its manufacturing subsidiary, Western Electric). This formidable technological enterprise has hitherto functioned partly with one hand tied behind its back. Plainly the company is now gambling on the chance that even though its assets will be reduced by nearly two-thirds, it will be able to grow more quickly when disencumbered of the unprofitable telephone companies. Three uncertainties lie ahead. The process of divestment may be more difficult than foreseen. Congress and the courts may decide that they do not like the settlement, or some parts of it. And the fields that AT&T hopes to enter are already partly occupied by other unregulated telecommunications companies. (There would

0028-0836/82/020085-02$01.00

have been howls of protest if the anti-trust suit against IBM had not also been dropped last week.) So for AT&T the future has the air of being an unaccustomed gamble, but a good one.

The chances are that it will succeed, and that the consequences will be profound, not merely in the United States. First, the emerging public telephone system in the United States will be an invaluable economic model for suggesting how such enterprises can be run on commercial lines. Nowhere else is such a task attempted. United States users of the telephone will most immediately discover that it costs them more to use the local telephone service as if it were unmetered water. Further ahead, however, they will find their habits changing, and telephones will be used increasingly for what they are best suited for in present circumstances — long-distance communications. It will be interesting to see how long telecommunications authorities elsewhere will be able to pretend this model is irrelevant to them.

The liberation of AT&T from the regulatory framework will also help to change the character of telecommunications. For several years it has been clear that technical innovation has outstripped the capital resources of the industry (and the capacity of potential consumers to buy its products). The result is that people who read in the technical literature of novel kinds of office switchboards, facsimile transmission by satellite, electronic mail of various kinds and high-density communications channels, have to put up with the much more rudimentary means of communication already in service. Competition from AT&T should help to bring down the prices at which these novel services are sold. More important, the entry of even a truncated AT&T into such fields should help to speed the exploitation of existing innovations as well as to sustain the pace of discovery.

But why all the bother? Can it really be of such great importance that people who have not yet learned to use pocket-size computers should be more able to install computer terminals in their living rooms? Or that people in Europe should be able to watch American television (and vice versa)? There is a widespread and unhealthy scepticism prompting these and other questions. The common underlying fallacy is to ignore the present importance of the telecommunications industry and to dismiss as unimportant the potential growth. Yet if the industrialized world wishes seriously to find something with which to occupy itself in the decades ahead, can it afford this insouciance?

How to save a university

The University of London is in danger of collapsing. It needs a recipe for survival.

For a quarter of a century, and in spite of a succession of supposed reforms, it has been clear that the University of London could not continue as it had become. The question now is whether it can survive. The request by University College, the university's largest college, to be supported directly by the University Grants Committee and not through the university's own bureaucracy (see page 88) is not intended as a threat to the continued existence of the federal structure. But that is what the effect will be. If University College gets its way, others — the London School of Economics, for example — will want the same, and will not easily be denied. And even though separate financing does not of itself mean separation, what would be left of the university's central administration would be even less able than at present to give the university a sense of coherence.

How, it will be said elsewhere, have the mighty fallen. Within living memory, the University of London was not merely the largest single university in the United Kingdom and the largest source of qualified physicians (which it still is) but a godfather to emerging universities in Britain and elsewhere in the British Commonwealth. The university was then an important source of academic qualifications (by means of its external degrees) for those studying on their own while, almost as a sideshow, it administered school-level examinations in most Commonwealth countries, old and new. In its heyday, the university was imaginative and flexible, setting up a number of internationally important postgraduate institutions. Although always a federation in the sense of being the umbrella beneath which several constitutionally autonomous educational establishments agreed to function, the university appeared as a unified academic institution because its examinations and degree systems were administered centrally. Under the pressure of disparate events, most of these activities have been shed. The emergent universities have emerged, and no longer need an avuncular guiding hand. Countries once eager for London's services as a school-level examiner increasingly prefer to look after themselves. The demand for external degree examinations fell away as access to universities became easier in the 1960s. And, for more than a decade now, the university had delegated to its constituent parts much of the responsibility for setting their own degree examinations, largely in recognition that any common system must inhibit the pursuit of excellence by the stronger colleges. At the centre of the university is now to be found little but an office.

The past year has shown how vulnerable is an entity like this. The federation has become so loose that its vice-chancellor at the time (Lord Annan) was less able than his colleagues elsewhere to protest convincingly at the British government's decree that overseas students' fees must be increased (in 1979) and at the proposed cut in university budgets. Lord Annan did his eloquent best, but since last summer his successor, Professor Randolph Quirk, has had little choice but to hope against hope that the plans for retrenchment at individual colleges will somehow add up to compliance with the instructions of the grants committee for the university as a whole. (The obviously necessary survey of the scale of teaching in various subject areas, put in hand last September, will nevertheless probably come too late to provide individual colleges with timely guidance.) The university has promised to put redundant academics on a central register, and has asked colleges about to hire staff to think first of people being put out of work elsewhere within the university. So far, however, there is little prospect that the university will be able to put together an academic plan for the years ahead. The committee set up to do just that, under Sir Peter Swinnerton-Dyer, has been pre-empted by events. And if a plan should emerge by accident from the work of the subject review committees, the chances are meagre that this would be adopted by the university's senate.

It will, however, be tragic if the university simply withers away because it has no way of deciding what to do or how to do it. But time is so short that almost any plan will be better than none. So it is that it falls to the vice-chancellor to do off his own bat what the university's maze of committees cannot accomplish, and to say what the future will be like. A few simplifying assumptions will help. First, University College (bigger than many other British universities) is, like Imperial College, big enough to look after itself but should pay for its financial independence with unbreakable promises of help for the smaller fry. It is absurd, for example, that research facilities remain as jealously protected as they are, or that colleges wishing to provide specialized teaching must usually provide it for themselves. Second, the London School of Economics merits a similar degree of independence by its success in recruiting students from overseas.

Third, the vice-chancellor's chief concern should be with the rest of the university — seven or eight smaller colleges and a host of postgraduate institutes. The past few months have shown clearly that even willing partners in schemes for collaboration are given pause by the stark truth that collaboration cannot preserve jobs at all the institutions concerned, and may also hurt the academic pride of many of the teaching departments. The moral is that there should be an academic plan for these smaller components of the University of London that will, in due course, make collaboration between them natural and relatively painless. Any plan would enable these small but distinctive parts of the university to know where they are likely to be standing some years from now. No plan is a recipe for the further erosion of the university — or even for an agreement among the rump that it too would like collective independence. In that case, there would be nothing left.

0028-0836/82/020086-01$01 00

Arkansas verdict against creation science

But battle now to move to Louisiana

Washington

Last week's ruling by a federal judge in Little Rock, Arkansas, that a state law requiring equal treatment of "creation science" and Darwinian evolution in public schools is unconstitutional, represented a significant victory for those who have argued that, even without any explicit reference to the Bible, such laws violate the required separation of church and state

Yet if this particular battle has been won, the war against the creationists is far from over Indeed both the publicity given to last month's trial in Arkansas and the apparent reasonableness of the demand for "balanced treatment" have in some ways helped the creationists' case Only minutes after Judge William Overton had announced his verdict, the state Senate in Mississippi passed by a substantial majority a virtually identical bill to the one which had just been declared unconstitutional in Arkansas

Judge Overton was uncompromising in his criticisms of Act 590, passed hurriedly by the state legislature in March during the closing hours of its 1981 session Declaring creation science as having "no scientific merit or educational value", he said that "the conclusion is inescapable that the only real effect of Act 590 is the advancement of religion"

The verdict came on a suit against the state which had been brought by the American Civil Liberties Union (ACLU) on behalf of 23 local religious organizations, biology teachers and school children ACLU had asked that the judge overturn the law on the grounds that the act constitutes an establishment of religion, abridges the academic freedom of both teachers and students, and is impermissibly vague, "all in violation of the constitution and laws of the United States"

During ten days of hearings at the beginning of December, ACLU produced a series of religious and scientific witnesses to support its arguments The former developed the claim that, whatever the wording of the act, they felt its intention to be clearly religious, since the particular set of circumstances which it implied for the origins of the Earth was only compatible, among available descriptions, with the version that appears in the Bible

Scientists called to testify on behalf of ACLU disputed claims made by creationist groups that conventional evolutionary theory is so full of holes that the alternative hypotheses they support are at least sufficiently plausible to deserve a hearing in a public school classroom They also claimed that creation science did not meet the criteria for scientific theories generally accepted by the scientific community, although this was disputed by some of the creationist witnesses produced by state attorney general Steve Clark as part of his defence of the law

In the end Judge Overton — as had been widely expected — agreed with ACLU's position But the strength of his criticisms of the supporters of the bill surprised even those who had been expecting a favourable verdict In a 38-page written opinion, the judge provided a detailed description of the reasons why he found none of the creationists' claims convincing and said that they had admitted that the law was "a religious crusade coupled with a desire to conceal this fact"

The judge criticized the creationists for not taking data and weighing them against alternative scientific data in an empirical way to reach their conclusions Rather, he said, "they take the literal wording of *Genesis* and attempt to find scientific support for it"

The verdict was, predictably, welcomed with relief by the scientific community The American Association for the Advancement of Science, whose annual meeting in Washington last week had spent much time discussing the implications of the creationist controversy, issued a statement saying that, in Arkansas at least, "teachers now can get back to teaching science, and students can get back to learning"

Similarly the National Association of Biology Teachers, co-plaintiffs in the ACLU suit, said that it was "gratified" by

Creationism judged a religion, not science

Washington

In his verdict, Judge William Overton said that the evidence presented during the ten-day trial "established that the definition of 'creation science' has as its unmentioned reference the first 11 chapters of *Genesis*", and that "references to the pervasive nature of religious concepts in creation science texts amply demonstrate why state entanglement with religion is inevitable" under the Arkansas law, referred to as Act 590

"The two-model approach of the creationists is simply a contrived dualism which has no scientific factual basis or legitimate educational purpose", Judge Overton wrote "The emphasis on origins as an aspect of the theory of evolution is peculiar to creationist literature Although the subject of origins of life is within the province of biology, the scientific community does not consider origins of life a part of evolutionary theory "

In line with arguments that had been presented by the American Civil Liberties Union, Judge Overton stated that the essential characteristics of science were (1) that it is guided by natural law, (2) that it has to be explanatory by reference to natural law, (3) that it is testable against the empirical world, (4) that its conclusions are tentative, that is, are not necessarily the final word, and (5) that it is falsifiable Creation science, he said, as defined in the Arkansas act, failed to meet these essential requirements

"Some of the state's witnesses suggested that the scientific community was 'close-minded' on the subject of creationism and that explained the lack of acceptance of the creation science arguments," Judge Overton wrote "Yet no witness produced a scientific article for which publication had been refused Perhaps some members of the scientific community are resistant to new ideas It is, however, inconceivable that such a loose-knit group of independent thinkers in all the varied fields of science could, or would, so effectively censor new scientific thought

"The methodology employed by creationists is another factor which is indicative that their work is not science A scientific theory must be tentative and always subject to revision or abandonment in the light of facts that are inconsistent with, or falsify, a theory A theory that is by its own terms dogmatic, absolutist and never subject to revision is not a scientific theory "

The next biology lesson is taken from the Book of Revelations

As he had indicated during the court proceedings last month, Judge Overton made no direct reference in his ruling to the status of evolutionary theory as a science

David Dickson

0028 0836/82/020087 02$01 00

the ruling, claiming that "school boards can now resist pressure to include creationism in science classes". Indeed, as a result of the Little Rock decision, a school board in Tacoma, Washington, last week stopped requiring the teaching of creationism in biology classes.

However, the dispute is not going to wither away and the next major test will come later this year in Louisiana, which also passed a law requiring equal treatment for creation science and evolution in its public schools last year. Ms Martha Kegel, the executive director for the state's ACLU chapter which is mounting a comparable challenge to that raised in Arkansas, said last week that she was "elated" not only by Judge Overton's verdict, but by the detailed critique of creation science that he had developed on the basis of the testimony delivered during the Little Rock trial.

Yet the Louisiana case is far from clear-cut. In the first place, the local judge is under no legal obligation to take Judge Overton's verdict into account, since it is a separate jurisdiction.

Second, the Louisiana bill omits some of the detailed provisions of the Arkansas law, for example its stipulation that creation science must include the notion that the Universe, energy and life were created "from nothing", a requirement which several religious witnesses said clearly implied the necessary existence of a creator. ACLU claims that this change only exacerbates the extent to which the bill is unconstitutionally vague, the creationists hope that this revision will remove the basis for some of the strongest objections.

Third, leading members of the creationist movement are likely to take a much more active role in the prosecution of the Louisiana case than they were permitted to do in Little Rock.

Meanwhile in Arkansas the state attorney general has yet to decide whether to implement his previous promise that he would appeal against the verdict if it went against him. And in ACLU, contingency plans are being discussed for Mississippi, in case it is decided that the law should be contested there as well. **David Dickson**

University of London

Separatists emerge

The University of London, parts of which already live with the threat of bankruptcy, now faces balkanization as well. Last week, University College, the largest multidisciplinary college in the university (with 6,000 students) formally asked that it should in future be dealt with financially as if it were an independent university, with its own grant allocation from the University Grants Committee.

The demand is more like gauntlet thrown down before the university's management than a unilateral declaration of independence. Sir James Lighthill, Provost of University College, nevertheless says that the college would continue to play a full part in the university even if, like Imperial College, it were directly financed.

Especially since last summer's delayed allocation of funds to the London colleges by the court of the university, University College has been a fierce critic of the court's procedures. Last year, Sir James Lighthill won acceptance of the principle that a college's success in obtaining research grants should count — in its favour — in the annual distribution. The precedent for his latest move is Imperial College, which has been directly financed for the past two decades.

The problem now facing the university court, the ultimate authority which shares out funds among the colleges, is tricky. It is certain to regard financial independence for University College as a dangerous precedent. But the court must also be conscious that with the impending retirement of the principal (its chief officer), Mr J R Stewart, together with some of his more experienced colleagues, its ability to administer its funds intelligibly may be further impaired.

Discontent about the court's procedures has been simmering since the summer, when the court translated the grants committee's targets for 1983–84 into financial allocations for the present academic year and target student numbers for two years ahead. One difficulty for the colleges is that they are required to adjust to reduced budgets without knowing whether their individual plans for the future will add up to what the grants committee expects of the university as a whole. This gap will be bridged only after the publication (expected next week) of the reports of the committees set up in September to consider the balance of teaching in broad subject areas.

Meanwhile, the non-medical parts of the university have made little headway with reorganization. The announced bethrothal of King's College and Bedford College has not led to marriage but to an agreement to associate. The plan for an association between Queen Elizabeth College (the smallest in the university) and Imperial College has been put on ice, partly because Queen Elizabeth College could not accept that the association should be contingent on conditions, such as the provision of new buildings, that could not be satisfied for some time to come.

The late starters have on the whole done best. Chelsea College, faced with starkly reduced numbers and the continuing cost of buying its new site, began the academic year with a draconian plan which entailed the elimination of whole departments, and is now in a position to make substantial economies while softening its plan. And Royal Holloway College, blessed with a huge site 20 miles from central London, is being reluctantly courted by various suitors hopeful that they may be able to turn their city sites into handsome dowries.

Academic censorship

Shadow ahead

Washington

Admiral Bobby Inman, deputy director of the US Central Intelligence Agency, last week dismissed as "somewhat disingenuous" the blanket claims of scientists to scientific freedom in the light of arrangements routinely made with private, corporate sources of funding, and said that the overlap between technical information and national security "inevitably produces tension".

Admiral Inman, who as head of the National Security Agency under the Carter Administration started a dialogue with the scientific community over how to handle potentially sensitive but unclassified research in cryptography, also urged cooperation between scientists and security agencies to find a mutually acceptable relationship "before significant harm does occur which could well prompt the federal government to overreact". He suggested that a potential balance between national security and science "may lie in an agreement to include in the peer review process (prior to the start of research and prior to publication) the question of potential harm to the nation".

The admiral's remarks, delivered to a session forming part of the annual meeting of the American Association for the Advancement of Science (AAAS) in Washington, provoked a strong protest from some of the scientists present.

Professor Peter Denning, for example, professor of computing at Purdue University and president of the Association for Computing Machinery, claimed that efforts to restrict the publication of technical research data reflected a growing protectionist mood in the government which would stifle scientific communication and ultimately prove destructive to the growth of new technologies.

Responding to such concerns, the board of directors of the AAAS later passed unanimously a resolution opposing government restrictions on the dissemination, exchange or availability of unclassified knowledge. Others who took part in the AAAS session, however, accepted that the issue was not clear cut, and that many of the government's concerns were legitimate — even if they had occasionally been executed over-zealously, or had had their legal ambiguity exploited in the past.

Dr Mary Cheh, for example, professor of law at George Washington University, said in a paper on the government control of private ideas that the real question was not whether the government was justified in imposing secrecy on scientific research, but how far its efforts should be permitted to go.

Similarly, Congressman Paul McCloskey presented a paper, read in his absence, describing his legislative efforts to introduce a new bill aimed at clearing up

0028-0836/82/020088-02$01 00

the ambiguities that allowed the government to prosecute *The Progressive* for publishing an article on how the hydrogen-bomb works, even though it was based on material taken from public library shelves

As Admiral Inman and others pointed out, however, the debate over the national security implications of scientific research is no longer purely a military question, linking up directly with concerns about the "export" of commercially valuable information through open publication

"Some of our most carefully nurtured technological advances have suffered from a haemorrhage of foreign technology transfer from international trade — the licit or illicit selling of everything from chips to detailed manuals — to explicit espionage efforts", the session was told by Mr Daniel C Schwarz, an attorney who, as general counsel to the National Security Agency, had helped draw up the proposed prepublication review procedure for cryptography research

Admiral Inman also suggested, though emphasizing that he was expressing a personal opinion only, that there were several other fields such as computer hardware and software, lasers, crop projections and manufacturing procedures where publication of certain technical information "could affect the national security in a harmful way"

He also reacted to the charge that the National Security Agency had not provided public proof of its concerns about the potential damage that could be caused by the publication of the results of cryptography by arguing that such information was often even more sensitive than the basic information itself

"Nowhere in the scientific ethos is there any requirement that restrictions cannot, or should not, when necessary be placed on science", he said "Scientists do not immunize themselves from social responsibility simply because they are engaged in a scientific pursuit "

He quoted several other areas, such as controls on genetic engineering research or on the protection of proprietary data, in arguing that there was nothing inherently wrong with an attempt to impose restrictions on science "Some of these restrictions are common sense, some are federal requirements, some are simply good business and some are good science," Admiral Inman said **David Dickson**

Relative prosperity

A gift of $1 million from Mr Harold McGraw, chairman of McGraw-Hill the publishers, has ensured that work on the Einstein papers can continue to completion But Dr John Stachel, the editor of the project for the past four years, says that although the gift is enough to ensure continuity, more money will be needed if the staff of the project is to be increased from two (at present) to the desired four or five

For the time being, work is concentrated on the early years of Einstein's academic life The intention is to include not merely extant letters and published papers but also ancillary documents Dr Stachel is pleased to have come across already a letter of commendation from Einstein's eventual colleagues at the Eidgenossische Technische Hochschule (ETH), Zurich (where Einstein went from the Patent Office in Berne) saying, in effect, that although Einstein was a Jew, he was "quite a nice Jew, not like the others"

At this stage nobody is prepared to guess how long the project will take, or how many volumes will eventually be published (by Princeton University Press) although there will certainly be a score of them Dr Stachel expects to be working on the project for twenty years

Polish crisis

Exiled students speak

Paris

Poland's "independent student association" was disbanded last week by order of the Ministry of Science, Higher Education and Technology According to this decision, the association was disbanded for continuing militant activity after the declaration of martial law Activists had, it is alleged, continued to distribute leaflets calling for strikes and other protest actions which represented a "flagrant violation of the decree on martial law"

The day after the decree, a group of Polish students, stranded in the West by the declaration of martial law, set up a "coordination group of the independent student association" with a provisional office in Paris The group intends to work mainly for the relief of academics and students interned in Poland under the martial law regulation At a press conference in Paris last week, however, it stressed that the current situation, with the threat that oaths of loyalty must be taken by academics and students who wish to continue working in the universities, will prove disastrous for higher education in Poland

It has therefore asked students throughout the world to press for the liberation of the interned students, and for all intellectuals to take a similar stand concerning intellectual and academic staff In particular, it called for a boycott of scientific, economic and sporting cooperation with "representatives of Jaruzelski, Moscow and the Eastern bloc" until martial law is lifted in Poland

One of the speakers at the conference, Miss Anna Krajewska, a philosophy student from Kracow, said that one of the major "sins" of the independent student association had been its participation in a plan to create a new international student organization independent of all political slant or affiliations

Recent announcements by General Jaruzelski's military government has accused the association of "striving to create a new anti-socialist student international organization and at the same time to break up the existing international students' association" (a reference to the Prague-based and socialist-oriented IUS)

According to official statements in Poland, the Ministry of Science, Higher Education and Technology (which is at present without a minister) feels sure that members of the former independent student association will "judge correctly" the extremist leaders who "abuse the confidence" of rank and file students By taking up studies, says the ministry, and "respecting the law", they can be sure of preserving their student status This is a clear hint that the current process of political "verification" now taking place in Polish industry will be imposed on students before they are allowed to resume their studies A meeting last week between the rectors of medical academies and political leaders suggests that in medical schools the process will be introduced even more rapidly and strictly **Vera Rich**

British medical research

Vacancy filled?

Dr J D ("Dai") Rees, from Unilever, is for the time being the Medical Research Council's preferred appointment as director of its National Institute for Medical Research at Mill Hill, in suburban London An appointment has become necessary because Sir Arnold Burgen, the present director, is leaving in the summer to become the Master of Darwin College, Cambridge A definite proposal has not yet been put to Dr Rees, it is understood

Dr Rees has been connected with the Medical Research Council for the past two years, since his part-time appointment as co-director of the council's Biophysics Unit based at King's College, London Recently he has played an important part in suggesting a new management structure for the National Institute, which has an annual budget of £8 million Part of this proposal, on which senior staff at the institute are being consulted, is that the new director should be advised by a four-member management committee empowered to determine the general pattern of research

Dr Rees, in his early forties, is a carbohydrate chemist by background who has established a dazzling reputation at Unilever by his work leading to the development of polysaccharides capable of lending physical structure to otherwise fluid materials The technique is now used commercially in the manufacture of ice cream and of instant desserts

More recently, Dr Rees has turned to cell biology, including the study of cell movement on surfaces

0028-0836/82/020089 02$01 00

Dr Rees's obvious attractions as director at Mill Hill include his combination of individual experience with his reputation as a scientist and his formidable reputation for getting on well with people

Among the questions to be settled before an appointment can be offered are an appropriate salary — the director of Mill Hill has traditionally been a physician whose salary has been linked with those of medically qualified academics There is also a question of the new director's freedom to make appointments of his own

US agricultural aid

Balance for all

Washington

A report by the General Accounting Office (GAO), the investigative arm of the US Congress, criticizes the ability of US universities to carry out agricultural research and technical assistance relevant to the needs of Third World countries

The report, recently published in Washington, focuses on the impact of legislation passed by Congress in 1975 which directed the Agency for International Development (AID) to find ways of strengthening and improving the involvement of US universities in solving the food problems of the developing nations. The action by Congress was meant to halt the decline in AID research grants to universities which had taken place in the early 1970s and covers projects totalling about $400 million

After a detailed assessment of the various initiatives taken under the new legislation, an amendment to Title XII of the Foreign Assistance Act, known as "Famine Prevention and Freedom from Hunger", the GAO concludes that progress in achieving its goal had been slow and in some cases virtually non-existent

The debate over the relationship between AID, Third World needs and the US research community has considerable significance for US foreign policy Increased assistance for agricultural research was one of the recommendations that won universal endorsement — including that of President Ronald Reagan — at October's summit meeting in Cancun, Mexico

The Reagan-appointed administrators of AID, who see Title XII as providing a firm basis for switching the emphasis of foreign aid towards technical assistance, particularly in agricultural research, claim that parts of the GAO report create an impression "which seriously understates the very substantial progress made during the first five years of Title XII"

However, Mr Herbert L Beckington, the agency's inspector general, commenting on a draft report, said that in general AID accepts its recommendations and intended to carry them out And AID deputy administrator Mr Joseph Wheeler told a recent meeting of the Board for International Food and Agricultural Development that plans were already under way to issue a policy directive clarifying the agency's commitment to the Title XII concept and to make implementation more effective.

AID officials emphasize that the legislation was originally intended to ensure that US universities with a tradition of agricultural research received adequate support to enable them to provide technical assistance to developing nations, a capability which they claim was eroded in the early 1970s as foreign-aid policy switched to commodity and credit agreements They accept many of the criticisms of the way in which technical assistance programmes have worked out in practice The GAO investigators, for example, found that many AID field missions distrusted teams sent out by US universities, claiming that members of such teams often lacked relevant experience of the problems they were meant to tackle.

The GAO report also criticizes the AID contract procedures in universities In some cases, for example, it is claimed that the agency has taken up to two years to approve the award of a contract to a particular university In addition, it says that the resource registry used to identify the best institutions and individual resources is not up to date, contains inadequate information and is cumbersome to use

Supporters of Title XII within AID, who feel that their efforts to implement the legislation effectively received only lukewarm support from the Carter Administration, have generally welcomed the GAO report and hope that the new Administration will prove more sympathetic **David Dickson**

Drug regulation in Brazil

Troubles building

Rio de Janeiro

The inauguration last month of a new headquarters for Brazil's National Institute for Health Quality Control underlines the urgent need to bring order to the chaotic system of marketing pharmaceuticals in Brazil Over the past ten years, Brazil has licensed on average 8,000 new brand names for drugs each year and the country is among the most liberal in the developing world for allowing the exploitation of pharmaceutical products

Brazil now ranks sixth in the world for pharmaceutical sales, and the market is dominated by the multinational companies which lobby in Brasilia against tighter regulatory measures Import licences are issued by the Ministry of Commerce which registered US $5 5 million of "pharmaceutical drug imports" and $300 million under the category "other pharmaceutical additives" during the first three months of 1981 Total sales last year amounted to almost $2,000 million, or six times the amount spent for all public health programmes in the country

Last month Brazil's president, General Figueiredo, opened a new $5 million seven-point star-shaped building for the National Institute for Health Quality Control and its director, Eduardo Peixoto, outlined the institute's main role — that of "moderating the free flow of licensing of pharmaceutical products in Brazil" Such steps are clearly needed, but the institute's predecessor, the National Secretariat for Health Vigilance (SNVS), given the responsibility for registering and controlling drugs six years ago, did not set a good precedent Its Central Control Laboratory functioned for three years with only two technicians, at the end of which time it received its new name — and now after a further three years, a new building

In the absence of effective controls, Brazil's pharmaceutical industry has gone on expanding despite the general economic recession, with the biggest growth area being psychotherapeutic drugs Almost all drugs can be sold over the counter in any pharmacy without a prescription and the average consumption per person is several times greater than in developed countries

One of the most alarming problems is the indiscriminate use of antibiotics Antibiotics are routinely bought to treat colds, and with six of the ten best-selling drug products being antibiotics there have been many examples of falsification by private laboratories and distributors The Maerson Laboratory of São Paulo was providing hospitals with "ziricillin" and "ampicillin" capsules which in fact contained pure starch And in Rio de Janeiro, after a series of complaints from consumers, Roche Laboratories discovered that their Bactrim balsam had been the victim of large-scale falsification by distributors and that several Rio pharmacies were selling an adulterated product diluted to half its normal concentration A further abuse of antibiotics came to light last November when the respected Adolfo Lutz Institute of Biology confirmed the accusation made by the president of the Pharmaceutical Association of São Paulo that the milk sold in São Paulo contained antibiotics used as preservatives

In a recent report, Dr Carlyle Guerra de Macedo, a consultant to the World Health Organization, denounced the "inefficiency of official controls which permits the marketing of many dangerous drugs" Many drugs are still available in Brazil, even with no prescription, long after they have been prohibited in the United States And many of the products on sale contain no warnings about the possible harmful effects of abuse These problems are further complicated by the fact that in many pharmacies the staff are inadequately trained and know little about the products they sell

The list of faults in the Brazilian way of marketing drugs is extensive, and the revitalized National Institute for Health Quality Control faces a daunting task

Maurice Bazin

UN technical development

Licence to spend

Washington

The General Assembly of the United Nations has agreed on a new financing system which came into operation at the beginning of the year, aimed at supporting efforts by developing nations to build up their scientific and technological capabilities.

In effect the resolution prolongs for one more year the interim arrangements for carrying out an ambitious plan of action agreed at the UN Conference on Science and Technology for Development (UNCSTD), held in Vienna in 1979. However, the form of the final arrangements is still under discussion.

The money so far received for the plan of action remains far below target. While it was agreed in Vienna, for example, to set up an interim fund under the auspices of the United Nations Development Programme (UNDP) to attract voluntary contributions of at least $250 million during 1980 and 1981, less than $40 million has been formally pledged.

The new resolution talks of setting up a financing system which would raise an annual $200 million over 1983–85. Several UN observers feel that this, too, is wildly optimistic, pointing out that Congress has even deleted the $10 million the United States was to have contributed to the fund from the foreign aid bill signed by President Reagan in November.

Perhaps more significant than the financial targets, however, has been the outcome of a dispute running since before the Vienna conference over who should control the distribution of the funds.

At UNCSTD the interim fund was established under UNDP, but at the same time a new Center for Science and Technology was created within the United Nations, under a new assistant director-general, whose principal responsibility was to provide secretariat services for an Intergovernmental Committee, open to all UN member states. The committee has had broad responsibility for the policy directions taken by the fund, but despite the strong efforts of some of the more militant developing countries, it was not given direct control of the fund.

During recent negotiations in New York on the resolution to set up a financing system that could be approved by the General Assembly, several of the more advanced developing nations again pressed for the Center for Science and Technology to be given greater responsibility for distributing funds.

Other countries opposed this move, however, on the grounds that if the management of the fund became too much an instrument of the more militant members of the Group of 77, this would further reduce the chances of the fund receiving significant resources from the developed nations.

Eventually, the latter view prevailed. The financing system approved by the General Assembly will have transferred to it the projects and personnel that now make up the interim fund, with the Intergovernmental Committee involved primarily through a small subgroup which will negotiate with potential donors. The resolution does not mention the centre.

It is hoped in New York that during the first year of these arrangements, definite procedures can be devised for raising donations from both developed and oil-producing countries along the lines endorsed by 20 developing nations at a meeting in Caracas in early October.

Observers in Washington remain sceptical. Although the State Department has offered moral support for the new initiative, Congress eliminated from the foreign aid bill $38 million which was to have gone to another special fund, the International Fund for Agricultural Development, on the grounds that much of the promised OPEC contribution had failed to materialize. In New York there is more optimism that a pragmatic compromise between political demands and technical needs can eventually be found.

Biotechnology

Going Dutch

Brussels

Dutch biotechnology researchers are awaiting with keen interest a report due early this year which is to define areas deserving future investment. A government-sponsored committee was set up last May under the chairmanship of Professor Schilpoloord of the University of Leiden with the aim of coordinating research in the Netherlands and increasing its emphasis on commercial applications.

The committee, which brings together experts from industry, the governmental applied research organization (TNO) and universities, is a by-product of the Dutch government's drive to stimulate innovation which was launched on the basis of a 1979 white paper which recommended that the government invest in new technologies.

A sum of 4 million guilders (£870,000) a year has been set aside for the biotechnology committee to allocate to selected projects. This is already being spent, with researchers at the University of Groeningen the first to benefit. The committee is expected to make recommendations on priority areas for funding which will include not only commercially viable projects but also related needs for developing, testing and producing genetically engineered microorganisms on a commercial scale.

The construction of a laboratory for work at P3 containment level is in progress under the aegis of TNO, and work should be completed in 1983. Whether the new laboratory will be used as soon as it is ready depends on advice from another committee set up last May — the Committee on the Ethical Implications of Genetic Engineering. This panel includes theologians, a professor of ethics, scientists and doctors, and is chaired by a former politician, Mr Oele.

At present the committee is undecided whether to go ahead with a separate report on research at P3 level followed by a general report or to leave the first issue to the final report even though it may mean the laboratory is unused for a while. Research at P1 and P2 levels is currently subject to authorization by municipal authorities but P3 research will be agreed on at national level. Industry in the Netherlands is at present battling against some decisions by municipal authorities which are alleged to be overcautious and restrictive. As an official of the government's science policy department confessed, "in Holland the whole issue is a political can of worms".

Jasper Becker

Cold comfort

Bombay

India has launched its first scientific expedition to Antarctica. A group of 20 scientists left Goa last month aboard the *Polar Circle*, a 600-tonne ship chartered from Norway. The cruise to Antarctica and back is to last 80 days and should include a total of 15 days actually on the ice doing experiments.

The Indian expedition is being led by Dr S. Z. Qasim, secretary to the Department of Environment and former director of the National Institute of Oceanography in Goa.

The Antarctic expedition, which will cost approximately £1.3 million, is one of several major projects of the newly created Department of Ocean Development, directly under Prime Minister Indira Gandhi. The expedition team consists of scientists from ten organizations including the National Institute of Oceanography, the Indian Meteorological Department, the Geological Survey of India and the Indian Institute of Geomagnetism. Two Norwegian scientists are with the expedition to assist in the operation of specialized equipment from Norway.

As well as collecting oceanographic and weather data, the expedition team will be looking for samples containing evidence that India was part of Antarctica before it broke away some 100 million years ago. During the cruise the ship will survey the ocean bed for nodules.

India becomes the third developing country after Chile and Argentina to reach Antarctica — shortly to be followed by China, which is planning to send its first expedition this year. So far there are no plans for a permanent Indian research station in Antarctica.

CORRESPONDENCE

Data on dioxin

Sir — In discussing the metabolism of chlorinated dioxins, Alastair Hay[1] reviews the epidemiological evidence for an association between soft tissue sarcomas and phenoxy herbicides

In fact the evidence in favour of an association is much stronger than he suggests He fails to mention that in addition to the findings of the surveys of two different groups of Swedish agricultural and forestry workers exposed to phenoxy acids and chlorophenols[2,3], studies of industrial workers exposed to these substances during manufacture in the United States have also been published A review of four such studies[4] showed that 3 of 105 deaths in the workers under observation had been due to soft tissue sarcomas This compares with 0 07 per cent of deaths in the total population of US males aged 20–84 Since the publication of this review a fourth (non-fatal) case of soft tissue sarcoma has been reported in one of these groups of men[5] A fifth case has been described in an employee of one of the American firms but it is not clear whether he was under observation as part of one of the published cohorts[6]

The Finnish study quoted by Alastair Hay has not followed a sufficient number of men for a long enough period to furnish other than weak negative evidence The study might easily have missed an increased relative risk of five

The epidemiological data cannot at present distinguish between a risk due to 2,4,5-T itself (or to related herbicides) and one which is due to contaminants of these compounds

Beat the clock

Sir – The anonymity of journals' referees has been much discussed A common nuisance is the tardy referee who sits on papers sometimes for months, and about whom authors can do little I believe these could be dealt with effectively if the anonymity of referees were maintained for say a month from dispatch to them of the manuscript After that the editor would automatically pass on the identity of the offender to the authors who could, and usually would, then take up the cudgels directly on their own behalf

I am sure this simple measure would effect a speedy acceleration of the turnover time of papers in editorial offices Many of us who are sometimes authors, sometimes referees, would, I am sure, accept this constraint on our latter function in the interests of our former

Niche work

Sir — Concerning H G Pickles' imagined "very small niche indeed" (Pharmacology Issues, *Nature* 1 October 1981, p 355) for *Journal of Ethnopharmacology* compared with *Journal of Cardiovascular Pharmacology*

I propose that more people can certainly be directly involved and interested in what plants they can eat or apply therapeutically or in any other useful way (because anyone may pluck, cultivate or look for plants) than can be directly involved in cardiovascular drugs (because they are not readily available)

All the best to cardiovascular pharmacologists, but please watch out for the relegation to niches (To be honest, I did think I was writing esoterica when I submitted my first article to *Journal of Ethnopharmacology* but there must be a lot of people out there in a lot of very small niches, because I received 48 reprint requests immediately following publication and they are still dribbling in)

Howard H Hirschhorn

Morphic field sports

Sir — The rather intemperate reaction of *Nature* to Sheldrake's hypotheses (24 September 1981, p 245), against which Josephson has protested (*Nature* 15 October 1981, p 594), is in part the result of Sheldrake's own choice of Bergsonian — or Paracelsan — explanations for the effect he postulates, and in part the result of noncommunication between biology and physics

Had Sheldrake said that the quantum interconnectedness might extend to macrosystems, including biological systems, I do not think that *Nature* would have felt that its virginity was in peril A model of interconnectedness does in fact flow from Bohm s idea of explication The experimental agenda is to see how far beyond the subatomic level this patterning extends If particles correspond to the asteroids and space-ships of a video game, appearing to behave as objects subject to cause–effect, but being in fact virtual displays built up from pulses which bear no translational resemblance to the "display", Darwinian evolution might well be (some would say, "must be") a video game of the same order, appearing to follow simple selection–adaptation principles, as the game-pieces appear to collide, explode and so on — but in fact determined by information from an implicate substrate

The relevance of interconnectedness to middle-order systems looks like a prime candidate for confirmatory research If it were confirmed, Sheldrake would be both right in principle and wrong in his postulated mechanism of "morphic fields" viewed in this way, his suggestion is far from absurd

One awaits with interest *Nature*'s reaction to the first book which points out that Bohm's model also blows up the convention of Helmholtzian mind That suggestion might prove even more alarming than a physics-based neovitalism

Dead-end theory

Sir — In a recent letter Darnbrough, Goddard and Stevely (*Nature* 2 December 1981, p 302) have argued in support of Creationism They claim that given belief in a God who reveals Himself in the structure of nature they "expect to find evidence consistent with His revelation of Himself" In their view "the fact that all things exist, and show evidence of design and purpose" is the only form of empirical evidence providing support for Creationism

In their arguments, your correspondents have forgotten that evidence which is merely consistent with a theory does not necessarily support that theory An illustration of this is that all possible evidence is consistent with the hypothesis that one minute ago a God created everything in the Universe, including our memories Clearly, for an observation to be consistent with a theory is only a necessary but not sufficient condition for it to provide that theory with evidential support

A fundamental problem with creation theories is that because the mechanisms proposed are supernatural, the theories fail to provide an explanation of natural phenomena which can be further investigated, developed and understood In fact, unlike present evolutionary theory, all theories which invoke a supernatural creator are scientific dead ends, failing to lead to new knowledge

This difference between creation theory and modern evolutionary theory can be illustrated by considering how each handles anomalous evidence Darnbrough, Goddard and Stevely claim that such evidence tends to be put to one side to await future investigations which will either show the evidence to be erroneous or permit its asssimilation into the original theory They neglect to point out that the development of creation theory through time, unlike evolutionary theory, has been one long retreat from the evidence In order to assimilate anomalous evidence, numerous *ad hoc* changes have been made to creation theory Such alterations were made in respect to the age of the Earth, the number of centres of creation, the number of separate creations and catastrophes through time, and the existence of variation within species, to name only the better known examples Meanwhile, evolutionary theory has not been without its own troubles, as the current debate over possible rates of evolution shows However, in the past, anomalies have been assimilated into evolutionary theory in a non *ad hoc* manner, leading to the further articulation and development of the theory This is a major difference between the two theories

What is being claimed here is that evolutionary theory is explanatory and has a heuristic function which helps our understanding of natural phenomena to grow Creation theory, however, is a pseudo-explanation which aids us not at all in our understanding of nature and leads us nowhere Naturally individuals may hold any metaphysical beliefs they wish, but the introduction of the notion of supernatural creation into scientific explanations should be resisted as contributing nothing, or worse, to our understanding of the world

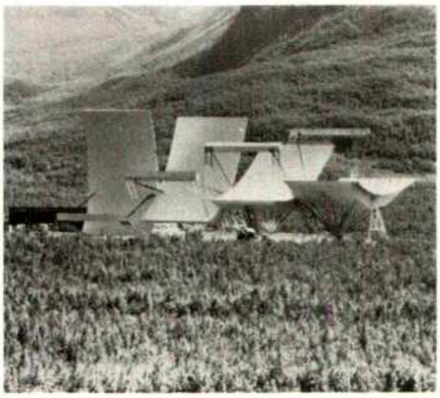

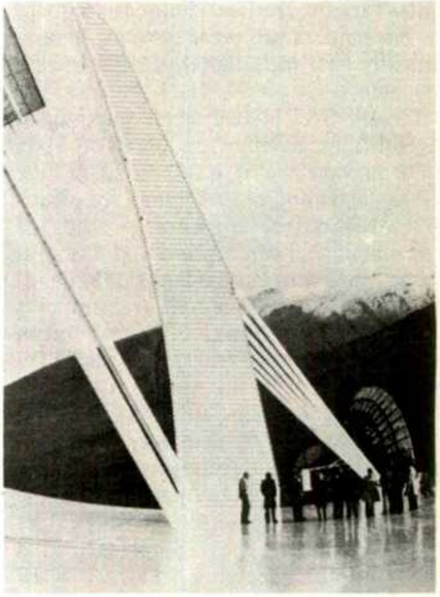

Fig.2 The EISCAT UHF dish and VHF antenna at Tromsø, Norway.

(EISCAT Scientific Association photographs, taken by Henry Rishbeth.)

FORMALLY opened by HM The King of Sweden on 26 August 1981, the European Incoherent Scatter programme (EISCAT) has begun its experimental task of probing the auroral ionosphere with ultrahigh frequency (UHF) radar. Next year, the very high frequency (VHF) transmitter should be commissioned and, after some frustrating delays due to transmitter problems, the system will then approach full operation.

The idea of a high-power radar in northern Scandinavia was mooted at the 1969 General Assembly of URSI, the International Union of Radio Science. Following years of planning and negotiations an agreement between national scientific organizations of six European countries, setting up the EISCAT Scientific Association with headquarters at Kiruna (Sweden), entered into force in December 1975. Three of the associates — CNRS of France, MPG of the German Federal Republic and SRC (now SERC) of the United Kingdom — each contribute one-quarter of the funding, the remainder coming from the 'Nordic' Associates — SA of Finland, NAVF of Norway and NFR of Sweden. Total capital expenditure to date is about £13 million.

The incoherent scatter technique[1], envisaged[2] in 1928 but not seriously proposed[3] until 1958, was demonstrated successfully in the latter year[4], and subsequently exploited at a few sites ranging from the magnetic equator in Peru to the sub-Arctic in Alaska. The technique uses a powerful radio beam at a frequency (between 40 and 230 MHz) much too high to undergo the almost mirror-like reflection from the ionosphere that is used in radio communication. The 'target volume' in the ionosphere is defined either by pulsing the radar beam and sampling the scattered echoes at a selected time delay, or geometrically by using separated, highly directional transmitting and receiving antennas. EISCAT uses both methods in its UHF system, but only the pulse method in its VHF system. Of a peak transmitted power of some megawatts, all but microwatts escape into space and mere picowatts are typically intercepted by the receiving antennas.

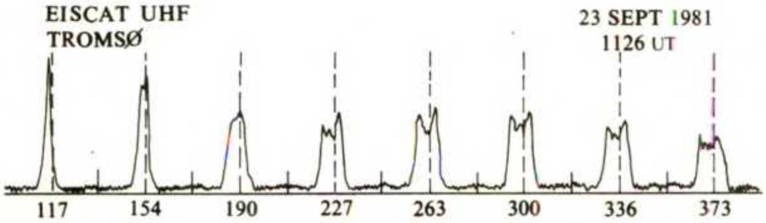

Fig. 1 Early EISCAT data: incoherent scatter spectra taken at eight heights over Tromsö, with approximately 37 km height resolution and 30 s integration. The amplitudes have not been corrected for the inverse-square dependence of scattered power on height. With increasing height, the spectral shape progressively changes from the narrow collision-dominated spectrum in the E region to the broader two-humped spectrum characteristic of the F region. The vertical dashes mark the transmitted frequency, and the vertical bars mark the limits of the 100 KHz passband of each spectrum.

The incoherent scatter spectrum (Fig. 1) depends on the spectrum of random thermal fluctuations of plasma density in the ionosphere. Analysis of the spectrum can yield a variety of parameters which (according to circumstances) may include ion density, composition and drift velocity, ion and electron temperature, and ion–neutral particle collision frequency (see ref. 1 and refs therein). Application of well established theory to these data gives several

---

0028-0836/82/020093-02$01.00

other ionospheric and upper atmosphere parameters, such as electrical conductivity and current density, electric field, neutral air temperature and wind velocity. Further information on electron density, temperature and drift velocity may be derived from the 'plasma sidebands' flanking the main spectrum, which are excited by photoelectrons or other low-energy particles[5-7]. In the highly active conditions of an auroral arc, with particle bombardment and large electrical currents, additional spectral features are produced by various plasma waves — the more so in an intensely heated ionosphere such as can be produced by a powerful high-frequency 'heating' transmitter. Incoherent scatter experiments have to be designed within a variety of constraints set by the equipment, the ionosphere and scientific requirements such as height and time resolution. The EISCAT system meets these constraints with a variety of radar techniques: frequency hopping, multi-pulse groups, phase-coded pulses, with digital data processing to match.

The EISCAT UHF system, operating at several frequencies centred at 933.5 MHz (0.32 m wavelength), has three 32 m fully steerable paraboloid antennas, of which that at Tromsó (Norway) is used for transmission and reception and those at Kiruna (Sweden) and Sodankylä (Finland) for reception only. The UHF transmitter is rated at 2 MW peak, 0.25 MW mean power and the VHF transmitter at 5 MW peak, 0.6 MW mean power. The VHF transmitting/receiving antenna at Tromsó (Fig. 2), 120 m × 40 m in size, can scan in the meridian plane by tilting its four panels; its beam can be offset by up to 20° from the meridian plane by inserting phasing cables in the feed system. The USSR plans to build an array for receiving EISCAT VHF signals at a Polar Geophysical Institute site in the Apatiti region.

EISCAT will primarily study the ionosphere, at heights of about 70–2,000 km. The list of measurable parameters shows that the technique can be used to study the upper atmosphere as a whole, not just the ionization. The aim is to build up an integrated picture of the structure, motions and energy sources and sinks of the upper atmosphere. Incoherent scatter observations at low latitudes, complemented by intermittent but more mobile data from satellites, have revealed much about the temperatures, winds and tides — in particular the motions driven by solar UV and X rays.

In addition the upper atmosphere receives a substantial input of energy from the magnetosphere, mainly at high latitudes. This input is very variable, peaking during auroral substorms when the input of electric currents and high-energy auroral particles sets up atmospheric gravity waves and circulatory winds which carry energy to lower latitudes. EISCAT will study such disturbances at their source, and its electric field measurements in the lower magnetosphere should help to elucidate one major outstanding question: the acceleration mechanisms of auroral particles. The auroral input is superimposed on another high-latitude input, not quite so rapidly varying — the input of momentum from the solar wind — probably through the impulsive connection and subsequent disconnection of the interplanetary and terrestrial magnetic fields as the solar wind flows past the Earth. This process sets up a large-scale circulation of plasma in the magnetosphere and ionosphere, which causes a related circulation of the neutral air above 150 km at polar latitudes.

EISCAT is also being used as a plasma diagnostic to study waves and instabilities in nature's vast plasma laboratory in the magnetosphere. This usage involves cooperation with the GEOS 2 satellite, kept in operation for the purpose, and with the West German ionospheric heating experiment at Trosmsø[8]. The 'plasma physics' aspect of EISCAT's work will be boosted when the VHF transmitter becomes operational.

EISCAT's immediate tasks include cooperation with several other programmes: the NASA Dynamics Explorer satellite, the USSR/French ARCAD 3 satellite, rocket experiments at ESRANGE, Kiruna, and optical interferometric measurements of upper atmosphere winds made from Spitzbergen. There are also investigations of small-scale ionospheric structure and (without the transmitter) radio-astronomical studies of interplanetary scintillations. An experiment is proposed in which UHF signals, transmitted from the Chatanika radar in Alaska and incoherently scattered from the polar ionosphere, will be received by EISCAT. EISCAT will also be used as a stratospheric radar. The move of the Chatanika radar to Greenland, planned for 1982, will intensify the scientific probing of the high-latitude ionosphere, particularly the magnetospheric 'polar cleft'. Meanwhile the processed EISCAT data being accumulated at the Rutherford Appleton Laboratory in the UK, and institutions in other EISCAT countries, will receive keen study from scientists. ☐

Do all laboratory mice trace back to a single female?

from M.F.W. Festing

IN this issue of *Nature*, Ferris, Sage and Wilson suggest that all the 'old' inbred strains of laboratory mice are descendants of one single female who lived some time between 1200 BC and AD 1920 (see p.163). At first sight this is an astonishing claim. Further reflection shows, however, that it is really not so unexpected, and that in view of the maternal mode of inheritance of the mitochondrial DNA (which they analysed) through the egg cytoplasm, the implications for the genetic pool of variation in laboratory mice are not as profound as they would at first appear to be.

What Ferris, Sage and Wilson have done is to study genetic variation in mitochondrial DNA (mtDNA), using eleven restriction enzymes. They sampled wild mice from a wide geographical distribution, as well as nine 'old' inbred strains (for example, BALB/c, C57BL/6 and DBA/2) and five colonies of inbred mice recently derived from wild mice. Among 20 wild mice they found 15 distinct types of mtDNA. All the old inbred mice had identical mtDNA, while four of the five new wild-derived inbred colonies differed from the old inbred strains. They concluded that the most likely explanation is that all the old inbred mice can be traced back to a single female who could have lived as recently as 1920.

Evidence that wild mice differ in many ways from laboratory mice is accumulating rapidly. The two groups differ in cell surface antigens[1], biochemical markers[2] and in some types of behaviour[3]. Several different wild populations have also been shown to carry chromosomal polymorphisms not found in laboratory stocks[4]. Such differences could have arisen as a result of the very different selective pressures on wild and laboratory mice, or as a result of a strong founder effect, or as a result of both these forces. Unfortunately, the historical records are very incomplete and provide little useful information on the domestication of our laboratory mouse stocks.

Mice have been domesticated since at least 1100 BC in China, and our laboratory stocks are believed to be descended from

---

0028-0836/82/020094-02$01.00

these mice following their establishment in Japan, and subsequent importation to Europe by traders in the early nineteenth century[5]. However, mice had also been independently domesticated in Europe, where they were frequently used for auguries and for pharmaceutical purposes.

Many of the old inbred strains may be traced back to the mouse colony established by Miss Abbie Lathrop in Grancy, Massachusetts, in the early part of this century. The origins of these mice are not known in detail, but they included fancy mice imported from Europe, as well as wild mice. Potter[6] describes this colony as "the American mouse melting pot", but there is very little information on the extent to which wild mice actually contributed to the gene pool. If there were crosses involving the wild mice, it is likely that wild males would have been crossed with tame females, which are far more likely to rear their young successfully in captivity. Thus, such crosses would not have altered the mtDNA, though they would have altered the nuclear DNA of the tame mice. However, not all the old inbred strains are derived from this colony. Strain SWR, one of the strains studied by Ferris, Sage and Wilson, was established from 'Swiss' mice which were not imported into the US until 1926[7]. This would imply either that the Swiss stock became contaminated by American mice, or that the common ancestral female lived some time before about 1920.

Although pedigree records are not available for our mouse stocks, study of other domestic species in which reliable pedigrees are available shows that a single individual often makes a substantial contribution to the development of a breed. Sewell Wright showed that in 1920 55 per cent of individuals of the Shorthorn breed of cattle could be traced back to a single bull, Favourite, born 20–24 generations previously in 1793. Similar close inbreeding was also found in several other breeds[8]. True, breeds of cattle cannot directly be equated with fancy mice. However, there were probably few tame mouse colonies in Europe during the early part of the nineteenth century, and when mouse fanciers did become organized in England in 1895, they were dominated by Walter Maxey, known as "father of the fancy"[9]. Those that found their way into research may well have been passed from one investigator to another as quite small groups, leading to a number of severe population bottlenecks.

If Ferris, Sage and Wilson's findings are not, therefore, too surprising, what are the scientific implications? First, it must be emphasized that what they have shown is that the *cytoplasm* of the old inbred strains may have come from a single female. Few, if any, of the nuclear genes need have come from that female. Thus, their results do not necessarily imply that laboratory stocks come from a narrow nuclear gene pool, as does the Shorthorn breed of cattle. Infusions of new genetic material from wild males, as may have happened in Miss Lathrop's colonies, would leave the mtDNA unaltered. This study will then be of most significance to developmental biologists who are interested in the relationship between the nucleus and the cytoplasm. In more general terms it also shows that the study of wild mouse populations can be extremely profitable — had Ferris and his colleagues not included wild mice in their studies, they would have concluded that mice are monomorphic for their mtDNA genomes[1]. It is hoped that their work will further stimulate studies of all types of genetic variation in wild mice, with the importation of much more genetic material into the laboratory. This should provide more insight into the genetics and evolution of the mouse, as well as providing many more variants which can be used as tools in the study of all aspects of mammalian biology. □

How black is the Universe?

from Richard A Muller

ALL but 10^{-9} of the known particles in the Universe are microwave photons of the 3K cosmic background radiation, discovered by Penzias and Wilson in 1965[1], and still the subject of intense study and interest. We believe that these photons are the Doppler-shifted remnant of the thermal radiation from the hot matter of the early Universe. The big bang theory[2] predicted that the photons would have a Planck frequency spectrum similar to that of the thermal emission from a black (that is, totally absorbing) object, hence the microwave signal came to be known as the cosmic blackbody radiation. True justification for this name came only recently, when the measurements of Woody and Richards[3] confirmed that the spectrum followed the general shape of the blackbody predictions.

But the Woody and Richards data also showed a small, statistically significant departure from the perfect blackbody curve. The radiation was slightly more intense than expected at the peak of the spectrum (near 1 mm wavelength) and somewhat less intense in the shorter wavelength region. Woody and Richards were properly cautious about this observation. They state

> "Although there is a statistically significant deviation from a Planck spectrum, there are serious limitations to the statistical analysis where systematic errors are likely. It is clear that another generation of measurement with better accuracy is required before any deviation from a Planck spectrum can be firmly established."

Others have been less cautious. The literature is now full of analysis of the 'observed distortion' by theorists starved for cosmological data. A likely candidate to produce a deviation from the blackbody shape is Compton scattering from free electrons released relatively late in the history of the Universe, during the era of star formation. However, the effect of Compton scattering is to depress the peak of the spectrum and to elevate the low frequency tail[4,5], this signature is opposite to that required. Other possible causes of distortion involve injection of energy in the early Universe, perhaps by early star formation. Unfortunately, most explanations involve so many parameters that one cannot feel confident that a true explanation has been found. Attention is more properly focused on the reality of the distortion.

Measurement of the millimetre region of the microwave radiation is extremely difficult because of interfering thermal emissions from the atmosphere, the Earth and the apparatus itself. Measurements must be made at high altitudes, from rockets, balloons, or satellites. Calibration requires a source with known emissivity and temperature similar to that of the radiation (3K). Accurate calibration is critical, a 27 per cent error could account for the entire distortion reported by Woody and Richards. (The peak would be reduced by the calibration error, the high frequency depression would be accounted for if the temperature of the radiation were 2.7K instead of 2.0K.) Woody and Richards calibrated their balloon-borne instrument on the ground both before and after their flight, and checked the calibration in-flight by observation of atmospheric O_2 emission lines. The check was consistent with the ground calibrations, indeed they have been unable to discover any mechanism which could cause a change in calibration during flight by the amount required to discredit the distortion.

Nonetheless, the in-flight calibration has recently been called into question. H Pickett, E Cohen and D Brinza[6] at the

0028-0836/82/020095-02$01 00

California Institute of Technology measured the pressure broadening of the oxygen lines on which the calibration check depends, and found a value larger than that assumed by Woody and Richards Ironically, as the Cal Tech group points out, the result is opposite to that needed to explain away the distortion of the microwave spectrum If we were to use as the primary calibration of the Woody and Richards experiment the oxygen emission measurements with the new widths determined by the Cal Tech group, we would conclude that the distortion in the spectrum is greater than originally reported It is not clear, however, that the in-flight oxygen measurements provide a better calibration than the ground-based measurements

Several experiments are being built which could independently test the existence of the distortion These include not only new spectrum measurements from balloons and satellites, but also high frequency observations of the cosine anisotropy caused by the motion of the Earth, comparison with existing low frequency anisotropy measurements[7-9] allows the shape (but not the overall normalization) of the spectrum to be determined[10] Woody and Richards give sound advice when they urge that we wait for "another generation of measurements" before accepting the deviation from blackness as real □

Islet cell precursors are neurones

from A G E Pearse

In a recent report Teitelman and her colleagues[1] describe parallel immunocytochemical studies on the localization, in mouse embryo pancreas, of the peptide hormone glucagon and the four catecholamine-synthesizing enzymes tyrosine hydroxylase (TH), DOPA decarboxylase, dopamine-β-hydroxylase and phenylethanolamine-*N*-methyltransferase A later study[2] has added insulin to the list The presence in a cell of all four enzymes would signify an adrenergic phenotype, of the first three a noradrenergic and of the first two only, a dopaminergic phenotype With the exception of the decarboxylase, the other three enzymes have been found only in cells of neuroectodermal origin The results of this elegant study once again bring into focus arguments concerning the derivation of the pancreatic islet cells and hence the whole basis of the APUD concept[3], particularly as it concerns the pancreatic and related endocrine cells of the gastrointestinal tract

APUD is an acronym, standing for amino precursor uptake and decarboxylation, that was first attached in 1968[4] to a short list of established or presumptive peptide-secreting cells which were situated either in established endocrine glands or diffusely in other regions of the body These two amino-handling functions were considered to be the most representative ones of seven cytochemical and ultrastructural characteristics possessed in common by the cells designated by the acronym Growth of the original list has brought the number of APUD cells to more than 40, if one includes, as one must, the magno- and parvo-cellular neurosecretory cells of the hypothalamus

Classically the islet cells are regarded as modified intestinal mucosal cells[5,6] For around a hundred years they have been considered to arise from stem cells in the pancreatic ducts[7], thus sharing a common endodermal origin with the cells of the exocrine pancreas[8] A more modern hypothesis, postulating a neural or neural crest origin for the cells, was first proposed in 1966 as part of the original APUD concept[4,9] This view required modification when work with rabbit embryos[10] and avian chimaeras[11] showed that the cells of the definitive crest could not be implicated as ancestors or antecedents of the islets, and the concept was then amended to derive them from committed neuroendocrine-programmed precursors arising in the embryonic ectoblast[12,13]

The real question is whether in the pancreas the four peptide-producing cells of the APUD series, and in the gut a further fourteen, are descendents *seriatim* and from day to day of multipotent endodermal stem cells, capable of differentiation into enterocytes, Paneth, goblet, duct, acinar and endocrine cells, or whether they arise by transformations occurring in committed neuroendocrine cells In the former case the enteropancreatic APUD cells cannot be regarded as sensory effectors, and they cannot be components of the postulated third division of the nervous system which the cells are held to constitute They can only be by-products of an exocrine, mucous, absorptive and duct cell replacement programme The functional characteristic of the cells, demonstrated cytochemically, and their independently long turnover time[14], have been held to support the second possibility and a neuroectodermal origin, or at least neuroendocrine determination, but morphological evidence has continued to support the unitarian (endodermal) hypothesis[15]

Teitelman and her colleagues[1] have now established, in embryonic mice, that the catecholamine-synthesizing enzyme TH appears in a population of cells in the developing (dorsal) pancreas at day 11 From day 12 to day 14 TH and glucagon can be localized, by serial immunocytochemistry, in identical cells and in up to 40 per cent of all cells containing either antigen At 14 5 days some of the TH cells are found to contain immunoreactive insulin rather than glucagon[2]

Expression of the catecholaminergic (dopaminergic) phase is transient, TH is no longer detectable in the glucagon or insulin cells, or in any other cell, after the fifteenth embryonic day It reappears, in a morphologically distinct islet cell, some time after birth This observation parallels the transient APUD facility exhibited by enteroendocrine cells in fish[16] and avian[17] embryos By contrast, the conversion of DOPA to dopamine can be detected in the endocrine cells of the developing mouse pancreas from the eleventh day onwards[18,19], and this function continues into the adult state It may also be observed that Teitelman *et al* have now provided concrete, rather than inferential, evidence of the presence of the decarboxylase in all the islet cells

What conclusions can be drawn from their investigations? Teitleman *et al*[1] formulate their own hypothesis which implies "that all the pancreatic A (glucagon) cells and, conceivably, other pancreatic endocrine cells originate by the transformation of precursors that express catecholamine biosynthetic enzymes" Their current formulation presumably includes the B (insulin) cells as originating in the same manner What, then, are the implications of this view? "All cells in the periphery that express one or more specific catecholamine biosynthetic enzymes are of neuroectodermal origin"[1] Do the pancreatic A and B cells constitute the first exception to this rule? That seems unlikely, to say the least

According to Teitelman *et al*[1] their data

A G E Pearse is Emeritus Professor of Histochemistry in the University of London at the Royal Postgraduate Medical School, Hammersmith Hospital, Ducane Road, London W12 0HS

clearly "tend to support Pearse's hypothesis" but "full validation of the developmental aspect of the APUD concept would require the identification of the germ layer from which the TH cells of the pancreas are derived" But the germ layer theory has probably outlived its usefulness The point at issue is not so much whether the APUD cell precursors are initially of endodermal or ectodermal origin, but rather whether they are an irrevocably neuroendocrine-determined self-replicating entity, needing only to effect relatively facile transformations to express functions clearly shown to be related, such as the co-production of amines and peptides[8] and the switch from one peptide to another, by modification of existing genes (gene splicing)[20] or by transcription of closely related genes in place of the original ones

Significant as they are, the investigations of Teitelman and her colleagues must clearly be extended to include further parallel studies of the association between TH and the other two pancreatic peptides, somatostatin and pancreatic polypeptide (or three if one includes gastrin, which is present in fetal islets) These matters require examination not only in the dorsal pancreatic anlage, where glucagon and then insulin are the first demonstrable peptides, but also in the ventral equivalent where, in the adult, pancreatic polypeptide comes to predominate We need to know which peptide, if any, is expressed by the morphologically distinct TH-positive cells of the adult mouse islet and, on a broader basis, whether the other peripheral and perhaps likewise the central APUD cells of the pituitary gland and hypothalamus express a transient or permanent dopaminergic function.

Conclusive proof of a neuroectodermal origin has now been established for just two of the enteropancreatic endocrine cells Confirmation of neuroendocrine status for the remaining sixteen cells can confidently be expected to follow ☐

The nature of galactic shells

from Gerard Gilmore

THE outer regions of galaxies are rapidly becoming as mysterious as their nuclei Kinematic studies have shown that the outer regions of disk galaxies like the Milky Way rotate with the same angular velocity as their inner regions, thus requiring the dominant contributor to the total mass of the galaxy (and the Universe) to be dispersed over a much larger volume than the luminous mass The nature and true distribution of this 'missing mass' is still unknown Now it seems that the luminous mass of stars in the outer regions of at least some galaxies is distributed in a much more ordered fashion than expected, with several narrow ripples and shells present at very large distances from the galactic nuclei In this issue of *Nature* (p 126), Carter, Allen and Malin from the Anglo-Australian Observatory present a detailed study of one such shell, which is 180 kpc (roughly twenty times the distance of the Sun from the galactic centre) from the nucleus of the galaxy NGC1344 Their observations show that the shells are probably normal stars with colours a little bluer than those of the more central regions of the galaxy

Why then do they form such dramatically sharp features? If the stars currently in the shells have spent their whole lifetimes in the outer regions of the galaxy without perturbation, their velocity dispersion in the radial direction would long ago have smeared out any sharp features in their spatial distribution The stars must, then, either be young or have had their orbits recently modified The first possibility was discussed by Fabian, Nulsen and Stewart[1], who suggested recent stellar formation from the gas driven from the galaxy by supernovae blast waves While young star formation cannot take place in regions of low gas density, Fabian *et al* showed that shocks can form as the outflowing gas meets the intergalactic medium, thereby producing locally enhanced density and permitting stellar formation These young stars will, however, fall back into the parent galaxy in the free fall time Thin shells will be visible only for times short compared with this, or perhaps 3 x 10^8 years The shells will therefore be populated predominately by luminous young stars, which are very blue — too blue, in fact, for consistency with the observations reported by Carter *et al*, which therefore require another explanation

One likely possibility is that the shells are remnants of galactic cannibalism Mergers of galaxies can produce an amazing variety of shapes and structures, possibly including shells Numerical simulations of the passage of a mass similar to that of a dynamically cool (disk) galaxy through the disk show a strong circular density wave to propagate outwards, possibly followed by lesser waves[2] In a recent simulation by Peter Quinn[3] of the Mount Stromlo Observatory in Canberra, a spherical and a disk galaxy were merged, and attention was focused on those particles ejected to large distances from the central region In all such simulations, dynamical friction causes the galaxies to merge after a bumpy meeting Initially, the disk passes through the main spheroidal component, then falls back in a series of rapidly dying oscillations, each of which ejects some of the disk stars In this way Quinn was able to generate three or four shells at large distances from the galactic centre, which bear some resemblance to those observed The stars in the shells are somewhat bluer than the main galaxy as they are preferentially ejected from the younger disk population, in agreement with observations The shells formed, however, are not as sharp as those seen, nor is it possible to generate the eight to nine separate features seen at different radii in NGC3923 Whether these are fundamental constraints or merely indicate the limitations of the current N-body simulations is not yet clear

Several examples of galaxies with shells are now known[4,5], in some cases with other evidence of anomalous features (loops, jets, active nuclei) which again suggest recent dynamical evolution Other explanations are, however, possible For example, the colour differential between the shells and the main body of the galaxy is also consistent with a mild radial decrease of the abundances of the chemical elements heavier than helium, which would not be surprising The shells would then have to be explained in terms of, for example, internal resonances in the velocity distribution inside the galaxy

A detailed explanation of the properties of the shells will require both a much more detailed numerical study of galactic mergers, and more specific observations of their properties David Carter is currently carrying out detailed surface photometry of several examples, to define their luminosity and colour distributions in more detail While spectroscopy would be highly desirable to define the kinematic properties in detail, it will be extremely difficult No emission lines have been detected from the shells, and the surface brightness is too low for easy absorption line studies (The surface brightness

reported for the outer shell of NGC1344 corresponds to a photon rate of one per arc second per Angstrom every 3 hours with the IPCS on the 3 9 m AAT) Similarly, no neutral hydrogen 21 cm emission has yet been detected Detailed study of the inner shells of this galaxy, while difficult, is possible, and should provide a fascinating insight into the processes of galactic cannibalism □

Developing synthetic vaccines

from Arie J Zuckerman

In this issue of *Nature* (p 158) Dreesman and his colleagues describe a step towards the production of a synthetic vaccine for hepatitis B infection Using a computer analysis of the amino acid sequence of a major polypeptide portion of the hepatitis B surface antigen they were able to predict hydrophilic regions which would be exposed on the intact 22 nm surface antigen particle and might represent antigenic determinants Two peptides containing one of these regions were synthesized and found to elicit the production of hepatitis B surface antibody in mice after a single injection

In the long term the development of synthetic vaccines is an exciting prospect The ultimate goal is the production of chemically synthesized multivalent vaccines that would replace current bacterial and viral vaccines[1] which can often contain many irrelevant microbial antigenic determinants, proteins and other materials that contaminate the essential immunogen and may cause untoward side effects

Although use of synthetic peptide vaccine may soon be a reality, the urgent need for protective immunization against hepatitis B virus — it is estimated there are 200 million carriers of markers of hepatitis B virus world wide — is likely to be met in the short term by more conventional vaccines Progress in their production and towards the creation of synthetic vaccines is reviewed below

Hepatitis B subunit particle vaccines

The development of a conventional vaccine has been hampered by the failure to grow hepatitis B virus in tissue culture and this has led to attempts to find other preparations which might produce active immunity (see refs 2,3), including the use of inactivated hepatitis B surface antigen purified from plasma of asymptomatic human carriers Guidelines for the preparation of experimental hepatitis B vaccines were suggested by the WHO Expert Committee on Viral Hepatitis[4], and the proposed requirements for hepatitis B vaccine were published by the WHO Expert Committee on Biological Standardisation[5] Progress in the safety and efficacy testing of such vaccines has been rapid The safety, immunogenicity and high protective efficacy of two such preparations have been demonstrated by placebo-controlled, randomized, double-blind trials in susceptible male homosexuals who are known to be at high risk of hepatitis B infection[6] and among healthy volunteer staff from 48 haemodialysis units[7] and in subsequent studies[8,9]

This type of subunit vaccine may, however, suffer from several disadvantages First, pooled plasma, with high titre of hepatitis B surface antigen (often *e* antigen positive), is required in large quantity from persistant carriers, and it is impossible to characterize each carrier donor on an individual basis Second, the supply of such plasma may be difficult to secure in the long term and live virus containment facilities are required for production Third, the manufacturing process is expensive (the reported cost of the vaccine recently licensed is 120–150 US dollars for three doses required for the first course of immunization) and possible extraneous/adventitious agents and other contaminants must be removed Strict safety testing of the vaccine is required, including tests for residual infectivity of hepatitis B virus in susceptible chimpanzees

Polypeptide vaccines

To overcome some of these problems, 'second generation' hepatitis B polypeptide vaccines containing hepatitis B-specific antigenic determinants associated with a nonglycosylated polypeptide with a molecular weight in the range 22,000–24,000 and a glycosylated polypeptide with a molecular weight in the range 26,000–29,000 have been prepared and tested for safety, immunogenicity and protective efficacy in susceptible chimpanzees[10-12] Although the two major polypeptide species of purified hepatitis B surface antigen of molecular weight 22,000 to 25,000 or 26,000 (variation exists between analyses of purified antigen from different sources), and a glycoprotein of molecular weight 28,000–30,000, have been frequently designated p22 or p23 and gp28, Peterson[13] considers that these should more properly be designated p25 and gp30, based on the probable true molecular weight of the protein as deduced from the DNA sequence of the viral gene and the results of amino acid analysis by various techniques

The advantages of polypeptide vaccine, derived from any source[14], include precise biochemical characterization, exclusion of genetic material of viral origin, exclusion of host- or donor-derived substances and potency[15] Disadvantages of polypeptide vaccines include low yield if strong ionic detergents are used for separation, although the yield has been substantially improved by the use of non-ionic detergents[16]

Genetic biosynthesis

Particularly attractive sources of antigenic material would be prokaryotic cells expressing hepatitis B surface antigen proteins Cloning of hepatitis B viral DNA and the production of small amounts of surface antigen have been reported by several groups and in significant amounts by Edman *et al* [17] Expression of hepatitis B proteins in eukaryotic cells has also been achieved in mutant mouse LM cells and in HeLa cells, but sources such as transformed heterotransplantable producer cell lines have not yet been licensed by any National Control Authorities for vaccine production Expression of glycosylated hepatitis B surface antigen in yeast cells has recently been reported by W J Rutter of the University of California, San Francisco, and this is potentially a most important development for large-scale *in vitro* production of an immunogen

Synthetic hepatitis B peptide vaccines

The feasibility[18] of developing synthetic vaccines was first demonstrated by the identification of the amino acid sequences responsible for immunogenic activity of the tobacco mosaic virus Such amino acid moieties can be synthesized and, when coupled to carrier protein, will induce the production of neutralizing antibody in experimental animals In 1976, Langbeheim *et al* [19] accomplished the neutralization of a bacterial virus with antibody elicited by a synthetic antigen The first example of successful active immunization against bacterial toxin — diphtheria toxin — using a synthetic antigen has been published recently[20] Diphtheria toxin is a single polypeptide chain of 62,000 molecular weight with two disulphide bridges The loop of 14 amino acids subtended by the disulphide bridge near the NH_2 terminus has been implicated in the toxicity and immunological specificity of the molecule A synthetic tetradecapeptide linked covalently to two different carriers elicited antibodies in guinea pigs which bind specifically with the toxin and neutralize the dermonecrotic and lethal effects

Induction of type-specific immunity has also been achieved using a synthetic peptide of *Streptococcus pyogenes* M protein containing only 12 amino acid residues[21] The immunogenicity of such small peptides points the way to the development of safe vaccines against streptococcal infections which cause rheu-

---

Arie J Zuckerman is Professor of Microbiology in the University of London at the London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT, and Director of the WHO Collaborating Centre for Reference and Research on Viral Hepatitis

0028-0836/82/020098-02$01 00

matic heart disease, and the efficacy of very small peptides will permit a large portion of the protein molecule to be disposed of, so reducing the chances of eliciting immunological cross-reactions against host tissues Possible approaches to the development of chemically synthesized hepatitis B vaccines were described a few years ago by several groups of investigators, and current progress suggests that such synthetic peptide vaccines are within reach

Valenzuela *et al* [22], and subsequently others, identified an 892 base pair region along the DNA strand of hepatitis B virus with the *adw* determinants using cloned DNA fragments, and the full sequence of the 226 amino acids coding for the 23,000–25,000 molecular weight polypeptide of hepatitis B surface antigen was predicted The corresponding sequence for the *ayw* subtype suggested that it differed in 16 amino acids[23] Employing an unpublished computer program designed by J E Kyte and R F Doolittle, which has been used to predict the internal and external residues of proteins with known structure, Lerner *et al* [24] chemically synthesized 13 peptides corresponding to amino acid sequences predicted from the nucleotide sequence for hepatitis B surface antigen Seven out of the 13 free or protein carrier-linked synthetic peptides elicited an anti-peptide response in rabbits Where used, the carrier protein was keyhole limpet haemocyanin in complete and subsequently incomplete Freund's adjuvant Antisera against four of the six soluble peptides, ranging from 10 to 34 amino acid residues long, reacted with the native antigen and also precipitated the 23,000 and 28,000 molecular weight major polypeptides of hepatitis B surface antigen Hopp[25] also used a computerized analysis of the amino acid sequences of the surface antigen protein to predict an antigenic site determinant An amino acid sequence of residues 138–149 was synthesized and examined for its ability to bind antibodies to a mixture of the *ad* and *ay* subtypes of hepatitis B virus Although the peptide bound only 9 per cent of the antibodies, the maximum binding capacity was not reached

Dreesman and his colleagues used a similar technique to predict two hydrophilic regions of the surface antigen molecule Two cyclic peptides, containing disulphide bonds in the region between amino acids 117 and 137, were synthesized The two synthetic peptides with amino acids 117–137 and 122–137 were incorporated into several adjuvants including Freund's complete adjuvant, alum, and multilamellar liposomes with and without muramyl dipeptide Groups of BALB/c mice were immunized intraperitoneally with each of the preparations Hepatitis B surface antibody was induced 7–14 days after inoculation in approximately 50 per cent of the mice in each group, and in four or five of six mice when the immunizing preparation of the 117–137 peptide was emulsified with Freund's complete adjuvant On day 21, the peak levels of antibody decreased in most groups of mice It should be noted that the antibody response was elicited in mice after a single injection without covalent linkage to a carrier protein

Thus, synthetic peptides may be used, in due course, as vaccines although mixtures of more than one of the peptides may be required Of the many questions which remain to be answered, the critical issues are whether antibodies induced by synthetic immunogens will be protective in susceptible non-human primates, and whether protective immunity will persist in chimpanzees and subsequently in man Nevertheless, it is clear that we are entering the era of antibody engineering, and the prospect of multivalent synthetic vaccines against a variety of microbial agents may well be within reach □

A problem for the theory of biological structure

from David Eisenberg

An unexpected result for the structure of the polyoma virus capsid is presented by Rayment, Baker, Caspar and Murakami on page 110 of this issue of *Nature* It is unexpected because it does not conform to the pattern, proposed by Caspar and Klug in 1962, for the assembly of 'spherical' viruses[1] Their scheme provided a description of highly symmetric structures related to the icosahedron, formed from identical protein subunits, and it seemed able to account for the structure and assembly of a wide variety of structures The central idea was that of quasiequivalent bonding in an icosahedron-like, near-spherical shell, each of many subunits can have an environment nearly equivalent (or quasiequivalent in the terminology of Caspar and Klug) to every other subunit (The importance of this may not seem very great unless you know that it is impossible to arrange more than 60 asymmetric objects in identical environments in a closed shell) The biochemical significance of quasiequivalent bonding is that each subunit forms nearly equivalent bonds to other subunits This equivalence of bonding means that the assembly can be simply encoded in the three-dimensional structure of the subunit It thus becomes easy to imagine how self-assembly of the virus coat might occur, simply through the repeated formation of nearly equivalent, low-free energy contacts

The Caspar–Klug theory has correlated many observations from electron microscopy and X-ray diffraction, and has been welcome in a field where experimental results are emerging at a rate far greater than principles Many previous results on structure and assembly have been consistent with the Caspar–Klug ideas The most striking are the monumental X-ray crystallographic structures of RNA plant viruses from the laboratories of Harrison and Rossmann[2, 3] Both studies revealed virus coats that display quasiequivalent bonding of the sort predicted by Caspar and Klug Thus the new report of decided non-equivalence of bonding of subunits in the polyoma virus coat is particularly startling

Previous analysis of electron micrographs of the polyoma capsid had shown that the sphere-like shell of a surface is built from 72 clumps of subunits, or 72 'capsomeres' Twelve of these are surrounded by five identical capsomeres and are thus termed pentavalent Sixty capsomeres are surrounded by six others and are termed hexavalent In the Caspar–Klug theory such an arrangement is called $T = 7$, where T, the triangulation number, describes the number of subunits and the nature of their quasiequivalence In a $T = 7$ shell, it was expected that there would $7 \times 60 = 420$ subunits, $12 \times 5 = 60$ of these in the pentavalent capsomeres and $60 \times 6 = 360$ of these in the hexavalent capsomeres What would permit nearly equivalent bonding is that each pentavalent capsomere containing five subunits would be surrounded by five other capsomeres, whereas each hexavalent capsomere containing six subunits would be surrounded by six other capsomeres This 'five around five' and 'six around six' arrangement results in each subunit having nearly the same environment as every other, and thus being able to

David Eisenberg is Professor of Molecular Biology in the Department of Chemistry at the University of California, Los Angeles, California 90024

0028 0836/82/020099-02$01 00

form nearly equivalent bonds to neighbours

In their electron density map, Rayment *et al* find unexpectedly that the hexavalent capsomere is a pentamer, as is the pentavalent capsomere Thus there appear to be only $(12\times5)+(60\times5)=360$ subunits of the major coat protein VP1 in the capsid, rather than the expected 420 The authors buttress their observation by citing studies of the molecular weights of the capsid and VP1 protein which suggest that there are indeed fewer than 420 copies

Another consequence of the hexavalent unit being a pentamer is that the bonding among coat protein subunits is distinctly non-equivalent. This is illustrated clearly in Fig 7 on page 114, where the non-equivalence can be seen by comparing panel *c* with panel *d*, and by comparing in panel *d* the various relationships of the five protein subunits of the central capsomere to the six surrounding capsomeres Figure 7*f* illustrates that the observed structure can be accounted for by three types of contact between neighbouring pentamers, a much more complicated pattern than the expected single type of contact

Such an unexpected result, even from the laboratory of a co-author of the Caspar–Klug theory which the result seems to challenge, will no doubt face some scepticism The refinement method used to obtain the phases for the 22 5 Å resolution electron density map is not the thoroughly tested and trusted multiple isomorphous replacement In place of heavy atoms to constrain phases, the refinement is constrained only by the icosahedral symmetry and overall dimensions of the capsid Rayment *et al* present control calculations that suggest the phase refinement procedure leads to a correct and unique result, and they conclude that "the similarity of the hexavalent and pentavalent capsomeres seen in the electron density map is an intrinsic feature of the virus capsid structure rather than some unaccounted artefact of the refinement procedure" The authors go on to suggest that simian virus 40 and other members of the papova family may all have capsids built of pentameric capsomeres Some workers in the field of biological structure, while finding all of this intriguing, may reserve final judgement until the study of polyoma structure has reached higher resolution, presumably with the aid of isomorphous replacement

If the capsomeres of polyoma and related viruses are in fact built all of pentomers, the ideas of Caspar and Klug are in need of some revision They sought to explain why icosahedral shells had been selected for the design of closed containers built from many identical subunits They came up with the elegant idea of quasiequivalence in an icosahedral shell built from 60*T* identical units, each unit can have nearly the same environment and hence form nearly equivalent bonds to neighbours If subunits do not all have similar environments, then the reason for the icosahedral shells is unexplained

The result of Rayment *et al* seems to transfer the problem of virus structure and assembly from the realm of completely symmetric structures, such as the quaternary structures of oligomeric enzymes, for which the principles are obvious, one step towards the realm of asymmetric structures, such as the ribosome and the tertiary structures of enzymes, where the principles still elude us

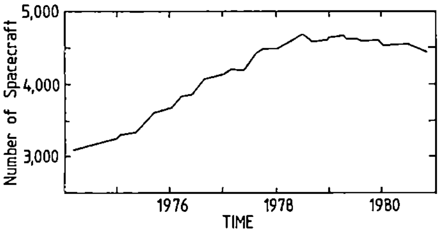
Spacecraft collisions

from David W Hughes

THE region of near Earth space, extending to about 5,000 km above the Earth's surface, contains many orbiting satellites and bits of satellites Collisions between them are inevitable and an estimate of just how frequently this will occur has now been made by L Schnal and L Pospíšilová of the Astronomical Institute of the Czechoslovak Academy of Sciences Their findings are published in a recent edition of the *Bulletin of the Astronomical Institutes of Czechoslovakia* (**32**, 310, 1981)

First, it was necessary to calculate the number of spacecraft per unit volume of space Satellites are continually tracked by radar systems in the US and the results published in *NASA Satellite Situation Reports* The figure below shows how the number of trackable orbiting bodies in near Earth space has varied in recent years



Between 1975 and 1978 the number was increasing at a rate of about 400 per year but more recently it has remained constant at just over 4,500 Radar sensitivity is sufficient to detect a large majority of objects bigger than 10 cm Sensitivity is less at high altitudes and for objects below heights of 500 km The number of small untrackable objects probably exceeds the number of trackable objects by a factor of 2

Orbital perturbations cause the argument of perihelion and the longitude of the orbit's ascending node to change fairly rapidly and this results in a uniform distribution of spatial density as a function of geocentric longitude Analysis of the orbital data leads to a value for the spatial density as a function of distance from the Earth and geocentric latitude The density is highest in the equatorial regions since every satellite must cross the equatorial plane twice per orbit To calculate the number of impacts per unit time one needs to know the relative impact velocity Schnal and Pospíšilova came to the conclusion that 7km s^{-1} was a reasonable overall value in near Earth space, agreeing with the previous estimate made by D J Kessler and B G Cour-Palais (*J. geophys Res* **86**, 2637, 1978) The computed mean is an averaged value resulting from two sets of collision velocities Satellite orbital inclinations are unevenly distributed, the majority being due to satellites moving from west to east One velocity set peaks at about 13 km s^{-1} and is due to head–on collisions between satellites orbiting in opposite directions The other set is peaked around the 1 –3 km s^{-1} region and is due to satellites catching each other up

The authors assume that the mean cross-section of a trackable body is 1 5 m^2 and that the untrackable objects have a mean cross-section of 0 001 m^2 The collision frequency, ΔC, is then given by

$$\Delta C = \tfrac{1}{2} \Sigma A\, V D^2\, \Delta S$$

where A is the assumed average cross-sectional area, V is the relative velocity, D the spatial density and ΔS an element of volume Integrating over all the regions out to a distance of 4,000 km from the Earth's surface results in an average collision frequency per year of 0 017 This is equivalent to around one spacecraft collision per 60 years, the estimated uncertainties being about 50 per cent.

This collision probability has remained reasonably constant over the last few years because the annual number of new launches has remained at about 120 per year Also, the recent solar maximum caused the atmosphere to expand and this has 'cleaned up' the lower regions by enhancing atmospheric drag and causing the small debris to spiral in quickly 'Killer' satellite tests and the accidental explosions of rocket motors have also decreased, thus lowering the number of small objects in near Earth space

A space crash would cause a rapid increase in the number of small orbiting bodies, some of which may be capable of fragmenting another satellite and thus creating even more fragments But still, with a rate of only one collision per 60 years or so, Schnal and Pospíšilová conclude that inner space is relatively safe □

REVIEW ARTICLE

Transcription of *Xenopus* 5S ribosomal RNA genes

Laurence Jay Korn
Department of Genetics, Stanford University School of Medicine, Stanford, California 94305, USA

The accurate transcription of 5S RNA genes when injected into the nucleus of Xenopus *oocytes or when added to an* in vitro *transcription system has allowed identification of the DNA sequences and one of the protein factors required for 5S RNA synthesis. Moreover, 5S RNA genes as part of intact chromosomes maintain a transcriptionally regulated state when injected into* Xenopus *oocyte nuclei. A detailed picture of the developmental regulation of 5S RNA gene expression is now emerging.*

DIFFERENTIAL gene expression underlies many of the differences between cell types. Gene expression in turn is controlled at several levels, with transcription especially subject to cellular regulation. There are two general processes which need to be understood in the transcription of eukaryotic genes: one is the nature of the DNA signals and other macromolecular components required for the initiation and termination of transcription of any gene; the other is how transcription is regulated throughout development, that is, what determines whether a particular gene is transcribed at a specific time and in a specific cell.

In the context of differentiation, the most interesting genes are those encoding proteins, as their products determine the cell phenotype. However, genes specifying a small, untranslated RNA molecule, the 120 nucleotide-long 5S RNA component of ribosomes, have so far yielded perhaps the most detailed picture of eukaryotic gene expression and its regulation. 5S RNA multigene families have been best characterized in the South African clawed toad, *Xenopus*, and are the focus of this review (Fig. 1). (For a more general review of eukaryotic gene transcription see refs 1–4.)

In contrast to most eukaryotic mRNAs, which are modified after transcription by the addition of a 5′ cap structure and a 3′ poly(A)sequence and by the removal of intervening sequences (see refs 4–6 for reviews), *Xenopus* 5S RNA does not undergo post-transcriptional modification[7,8]; the primary transcript is mature 5S RNA. This has facilitated the development of methods for transcribing purified 5S DNA (DNA containing the 5S RNA genes and flanking spacer sequences). When injected into the nucleus of *Xenopus* oocytes[9–11] (immature, unfertilized eggs), or incubated in a cell-free extract[8,12–15], 5S DNA is accurately and efficiently transcribed (Fig. 2). These transcription systems have helped identify the DNA sequences and other macromolecular components required for faithful synthesis of 5S RNA.

Not only are the 5S RNA genes well suited for transcription studies, but they are also amenable to investigations of the regulation of gene expression during development. In amphibians, there are two major classes of 5S RNA genes[16], the 'oocyte type'[17,18] and 'somatic type'[18]. The more abundant class of genes specifies oocyte-type 5S RNA; these genes are transcribed (active) during oogenesis, but are not transcribed in somatic cells[17,18]. In contrast, the somatic-type 5S RNA genes are expressed in somatic cells as well as in oocytes[18]. In the frog *Xenopus laevis*, transcripts from these two types of 5S RNA genes are the same length, but differ in sequence by six nucleotides[18,19], which allows the two types to be distinguished experimentally. The regulation of 5S RNA synthesis during development is discussed below.

Expression of 5S RNA genes in injected oocytes

A method for accurately transcribing purified genes was needed to identify the DNA sequences required for RNA synthesis. The transcription of purified 5S DNA after injection into the nucleus of *Xenopus* oocytes was the first example of faithful transcription of an isolated eukaryotic gene (Fig. 2)[9]. In initial

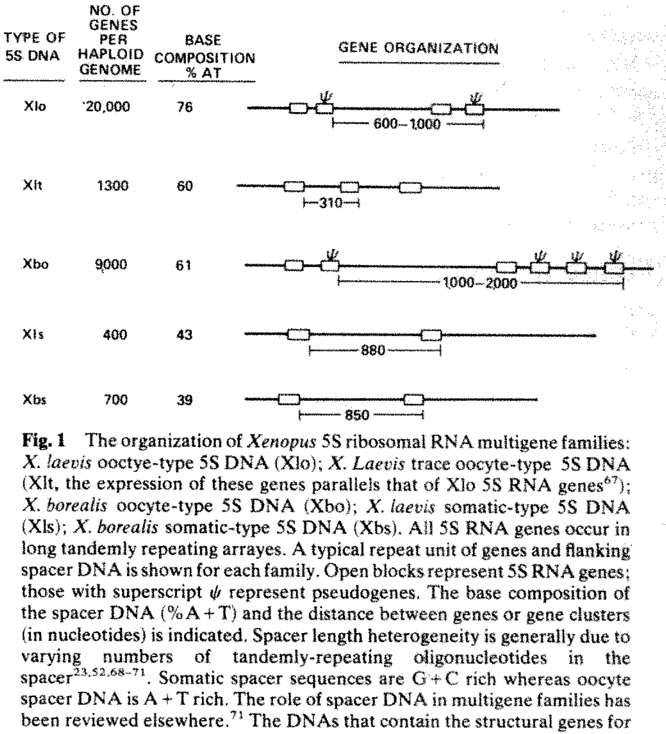

Fig. 1 The organization of *Xenopus* 5S ribosomal RNA multigene families: *X. laevis* ooctye-type 5S DNA (Xlo); *X. Laevis* trace oocyte-type 5S DNA (Xlt, the expression of these genes parallels that of Xlo 5S RNA genes[67]); *X. borealis* oocyte-type 5S DNA (Xbo); *X. laevis* somatic-type 5S DNA (Xls); *X. borealis* somatic-type 5S DNA (Xbs). All 5S RNA genes occur in long tandemly repeating arrayes. A typical repeat unit of genes and flanking spacer DNA is shown for each family. Open blocks represent 5S RNA genes; those with superscript ψ represent pseudogenes. The base composition of the spacer DNA (%A+T) and the distance between genes or gene clusters (in nucleotides) is indicated. Spacer length heterogeneity is generally due to varying numbers of tandemly-repeating oligonucleotides in the spacer[23,52,68–71]. Somatic spacer sequences are G+C rich whereas oocyte spacer DNA is A+T rich. The role of spacer DNA in multigene families has been reviewed elsewhere.[71] The DNAs that contain the structural genes for *Xenopus* oocyte- and somatic-type 5S RNAs have been isolated and cloned[51,52,67,72]. The nucleotide sequence of 5S RNA[17–19,23,73] and the DNA sequence of a complete repeat unit of each type of 5S DNA has been determined[13,23,52,68,74,75]. The dominant 5S RNA sequence of each of the five types of *Xenopus* 5S RNA differs from that of the other types by one to several nucleotides[19]. The nucleotide sequences of 5S RNA from numerous other organisms have recently been reported[76]. A structure resembling the 5S RNA gene, a 5S 'pseudogene', which differs in sequence from the normal 5S RNA gene by ~10%, is present in every repeat unit of *X. laevis* oocyte-type 5S DNA[75,77,78] and in some repeat units of *X. borealis* oocyte-type 5S DNA (ref. 23 and L J. K. and D. D. Brown, unpublished results). In *X. borealis* oocyte-type 5S DNA, the number and relative position of genes and pseudogenes in each cluster is variable (ref. 23 and L. J. K. and D. D. Brown, unpublished results). Pseudogenes can be transcribed by injection into oocytes[79] or by adding them to an *in vitro* system[23,48]. There are no pseudogenes in somatic-type 5S DNA[52]. The structural organization of the *Xenopus* 5S RNA genes has recently been reviewed[80].

0028-0836/82/020101—05$01.00

experiments, the template consisted of 5S DNA containing many tandem-repeat units of 5S RNA genes and surrounding spacer DNA (see Fig. 1 legend). The subsequent finding that a single cloned 5S DNA repeat can support accurate and efficient synthesis of 5S RNA when injected into oocytes (Fig. 2)[10,11] demonstrated that each repeat unit contains all the information necessary for its own transcription. This eliminates the possibility that a site at the beginning of an array of tandemly repeating 5S RNA genes is essential for transcription of all the genes in the array. Further delineation of the specific nucleotide sequences and other factors required for accurate transcription was facilitated by the development of an *in vitro* transcription system.

Expression of 5S RNA genes *in vitro*

As purified RNA polymerase does not faithfully synthesize 5S RNA from naked 5S DNA, but transcribes faithfully chromatin containing 5S DNA[20], it was clear that either certain structural features of chromatin or chromatin-associated components are required for accurate transcription. Unfortunately, chromatin fractionation has not led to the further identification of factors for transcription. Instead, the identification of transcription factors has come primarily from soluble *in vitro* transcription systems using purified 5S DNA and cell extracts.

The first such *in vitro* transcription system consisted of manually isolated oocyte nuclei, disrupted by gentle pipetting and clarified by low-speed centrifugation[8]. The supernatant accurately and efficiently transcribed cloned 5S DNA (Fig. 2). An *in vitro* transcription system capable of synthesizing 5S RNA can also be made from whole oocytes[14] and from extracts derived from cultured somatic cells[15,21,22].

The extracts used in these *in vitro* transcription systems, whether prepared from oocytes[8] or somatic cells[21], support 5S RNA synthesis from both oocyte- or somatic-type 5S RNA genes. Thus, although they efficiently and faithfully transcribe 5S DNA, the *in vitro* systems do not show any developmental control. However, using such systems, significant progress has been made in identifying the DNA sequences and other factors required for accurate transcription of 5S RNA, as reviewed below.

Transcription initiation signals

The minimum DNA sequences required for initiation of 5S RNA transcription as well as the sequences which influence the rate or precise site of initiation have been determined by correlating DNA sequence with transcriptional activity. Specifically, DNA sequences altered *in vitro* and recloned have been tested for their ability to support RNA synthesis.

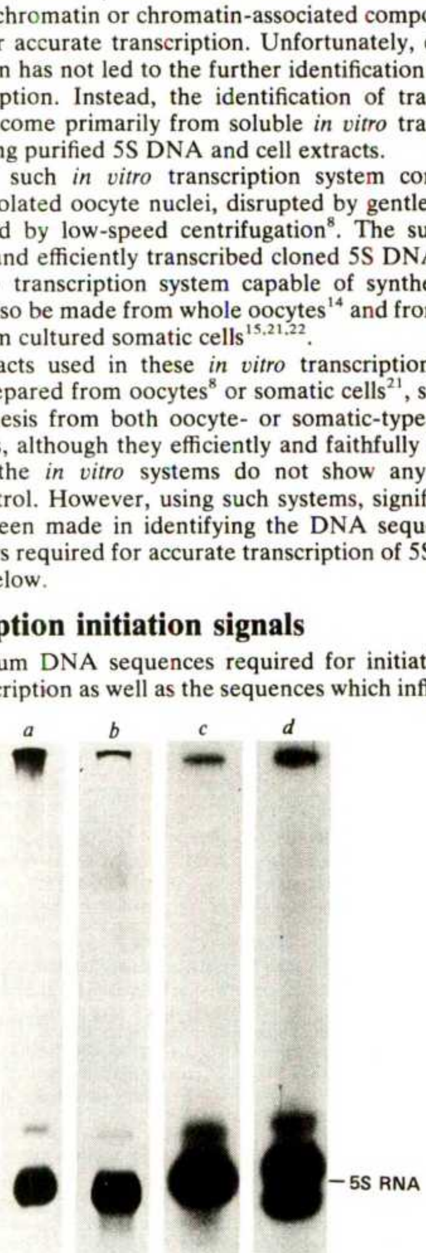

Fig. 2 Polyacrylamide gel electrophoresis of radioactive RNA synthesized after injection of the following types of 5S DNA into *Xenopus* oocytes (*a*, *b*) or after addition of 5S DNA to an *in vitro* transcription system (*c*, *d*). *a*, High-molecular weight genomic Xlo 5S DNA; *b*, plasmid containing Xlo 5S DNA; *c*, plasmid containing Xbs 5S DNA; *d*, plasmid containing Xbo 5S DNA. (Reproduced with permission from Brown and Gurdon[10] and Brown *et al.*[13].)

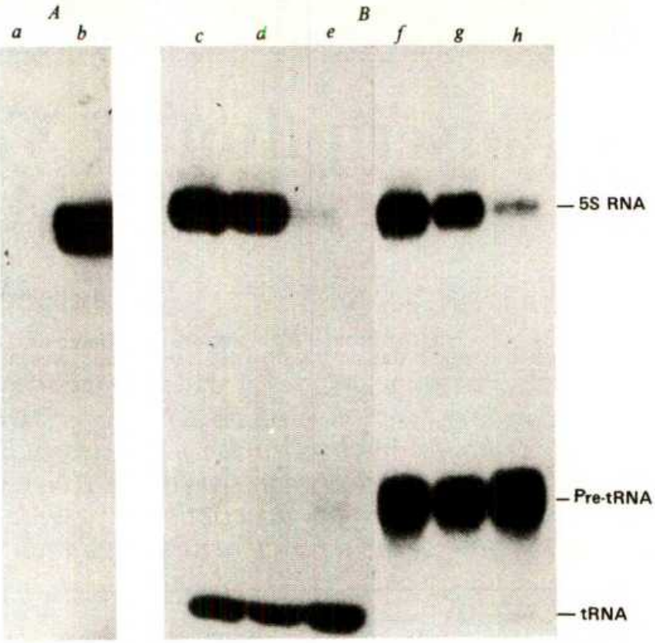

Fig. 3 *A*, polyacrylamide gel analysis of RNA synthesized in an *in vitro* transcription system containing a *Xenopus* egg S100 with no additions (*a*), or supplemented with TF IIIA (*b*). The egg contains very low levels of TF IIIA. This experiment shows that TF IIIA is required for 5S RNA synthesis *in vitro*. (Reproduced by permission from Honda and Roeder[37].) *B*, effect of antibodies against TF IIIA on 5S RNA synthesis. Transcription in an oocyte extract (lanes *c*–*e*) or a somatic cell extract (lanes (*f*–*h*) was performed with a mixture of a cloned 5S RNA gene and a cloned tRNA gene. Lanes *c* and *f*, no additions; lanes *d* and *g*, plus non-immune IgG; (lanes *c*–*e*) or a somatic cell extract (lanes *f*–*h*) was performed with experiments show that TF IIIA is required for 5S RNA synthesis, but not tRNA synthesis. The oocyte, but not the somatic cell extract processes tRNA transcripts. (Reproduced with permission from Pelham *et al.*[21].)

It is known that each repeat unit of 5S DNA contains all the signals required for accurate initiation of 5S RNA synthesis as individual cloned repeat units are transcribed accurately when injected into oocytes[10,11]. Furthermore, deletion of almost all the A+T-rich spacer sequence preceding the 5S RNA gene does not affect transcription[23,24]. In contrast to the situation in bacteria, where promoter sequences are located in the 5′ flanking region[25–28], the minimum sequence required to direct initiation of transcription of 5S DNA has, surprisingly, been shown to lie near the centre of the gene[29,30]. A series of deletions of the *Xenopus borealis* somatic-type 5S RNA gene which extend varying distances into the gene from the 5′ or 3′ ends were constructed. These genes have been characterized by DNA sequence analysis and tested for expression in nuclear extracts. It was found that the entire 5′ flanking sequence can be deleted without loss of 5S RNA gene transcription[13,29]. A transcript of approximately the correct size is still produced even when the first 50 nucleotides of the gene are deleted, although transcription is abolished by deletions extending to nucleotide 55 or beyond[29]. Similarly, initiation is not affected by deleting the 3′ flanking region or by deleting the 3′ end of the gene as far as nucleotide 83, but is abolished in a gene deleted to nucleotide 80 (ref. 30).

The deletions from each end of the 5S RNA gene identify a central region between nucleotides 50 and 83 which specifies transcription initiation. RNA polymerase initiates transcription at an approximately fixed distance upstream from this control region. For example, when a DNA fragment consisting of the central region (nucleotides 41–87) was inserted into plasmid

DNA, it directed initiation at a site ~41 nucleotides upstream[30]. In addition, 5S 'maxigenes' were constructed in which 6 or 20 nucleotides were inserted between the control region and the normal site of transcription initiation. In each case, transcription started within the gene rather than at the usual initiation site[29].

The precise site and rate of transcription initiation is influenced by sequences at or surrounding the start site[29,31–33]. Deletions leaving at least 26 nucleotides preceding the 5S RNA gene are unaltered in their transcriptional efficiency[31]. In contrast, deletion mutants with a shorter 5′ flanking region are transcribed with decreased efficiencies. Furthermore, deletion of 5′ flanking sequences can also allow heterogeneity in the initiation site[29]. These 5′ flanking sequences may include certain oligonucleotides that share homology with the flanking region of other genes transcribed by RNA polymerase III[13,23]. The exact site of initiation may also be influenced by the preference of this enzyme for starting transcription with a purine residue[12,23]. Moreover, an examination of initiation sites of transcription by RNA polymerase III reveals that the initiating purine is generally flanked by pyrimidines (Pyr^{-1}Pur^{+1}Pyr^{+2})[12].

Factors required for accurate transcription initiation

As discussed above, purified RNA polymerase III (the enzyme which transcribes 5S DNA *in vivo*; for review see ref. 34), and 5S DNA are not sufficient for 5S RNA synthesis *in vitro*. To search for other components which might direct accurate initiation, oocyte homogenates have been fractionated. In addition to RNA polymerase III, at least two protein factors are required, one of which has been purified (Fig. 3)[35,36]. Antibodies raised against this purified protein, transcription factor TF IIIA, inhibit 5S RNA synthesis *in vitro* (Fig. 3)[21,37]. When TF IIIA is mixed with 5S DNA, it binds to a region in the centre of both oocyte and somatic 5S RNA genes (nucleotides 45–96)[35]. This region includes that required for initiation of transcription (nucleotides 50–83)[29,30]. Furthermore, the ability of deleted fragments of 5S DNA to bind TF IIIA correlates with their ability to transcribe 5S RNA *in vitro*[38]. These results suggest that the influence of the central region on transcription initiation is mediated by TF IIIA.

A protein that shows immunological cross-reactivity with TF IIIA has been isolated from somatic cells[21]. It is unknown whether this protein, or the small amount of TF IIIA which is also present in somatic cells, is the factor required for 5S RNA synthesis in these cells. However, TF IIIA is not required for the expression of other genes transcribed by RNA polymerase III (Fig. 3)[35].

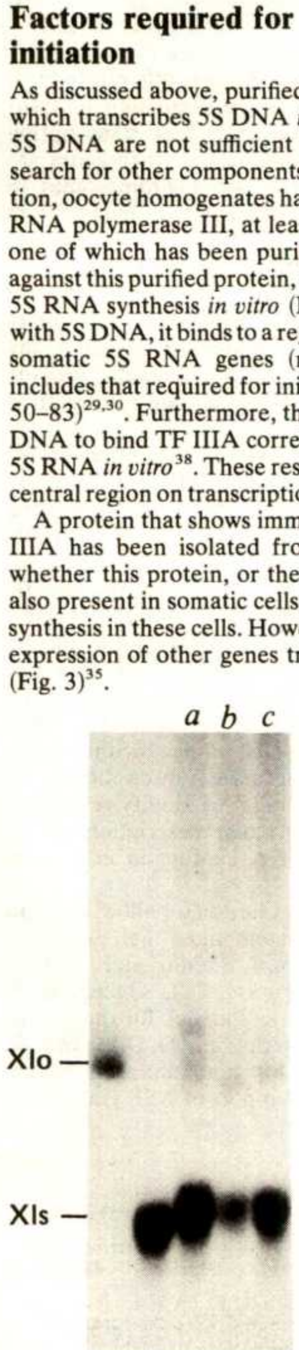

Fig. 4 Polyacrylamide gel analysis of RNA synthesized in *Xenopus* oocytes. 5S RNA genes in somatic nuclei injected into *Xenopus* oocytes continue to transcribe somatic-type 5S RNA, but do not reactivate the oocyte-type 5S RNA genes[64]. Approximately 500 somatic nuclei prepared by lysolecithin treatment of *X. laevis* kidney cells growing in culture[81] were injected into the nucleus of individual oocytes. The RNA from a single oocyte was electrophoresed in each lane of a non-denaturing polyacrylamide gel (lanes *a–c*). Xlo and Xls 5S RNA markers are indicated. The non-denaturing gel system resolves RNA molecules of the same length but which differ in sequence (for example, Xlo and Xls 5S RNA)[64]. (Reproduced with permission from Korn and Gurdon[64].)

Transcription initiation signals for other eukaryotic genes

As reviewed above, the sequence which directs the initiation of transcription of the *Xenopus* 5S RNA genes is contained within the gene. Whether this finding is general remains to be determined, but probably depends on the polymerase responsible for transcribing the gene in question. Experiments analogous to those on the *Xenopus* 5S RNA genes show that an intragenic sequence also controls initiation of transcription of the 5S RNA genes in the newt *Notophthalmus*[39]. Other genes transcribed by RNA polymerase III are controlled in a similar manner to the 5S RNA genes; the control region is within the gene. DNA fragments containing tRNA genes from *Xenopus*[40], *Drosophila*[41] and *Bombyx*[42–44], in which the 5′ flanking sequence has been deleted, can still support accurate transcription initiation when injected into the nucleus of *Xenopus* oocytes or when added to extracts from these nuclei. In contrast, a fragment containing the entire 5′ flanking region and the first 30 nucleotides of the *Xenopus* tRNA$^{\text{Met}}$ gene, but lacking the rest of the gene, cannot support tRNA synthesis[45]. A single base pair change in the middle of the yeast SUP4 tRNA$^{\text{Tyr}}$ gene (position +56) also prevents initiation of transcription[46]. These results suggest that tRNA genes, like 5S RNA genes, contain within the gene a control region which directs transcription. There is also evidence supporting an intragenic control region for the adenovirus VA RNA gene[33]. Sequence homologies have been reported between the 5S RNA gene control region and analogous internal regions of the adenovirus VA RNA gene and tRNA genes[30,33,46].

The other eukaryotic RNA polymerases seem to require different DNA sequences for initiation of transcription. RNA polymerase II transcribes the genes which specify mRNAs for proteins. Deletion of the 5′ flanking sequence of these genes prevents their expression *in vitro* (for review see ref. 4), which implies that DNA signals in the region preceding the gene are essential for transcription by RNA polymerase II. In contrast, the region immediately surrounding the initiation site appears to be critical for gene transcription by RNA polymerase I. Preliminary results indicate that for the *Xenopus* 18S and 28S rRNA genes, the sequence defined by nucleotides −12 to +16 is essential for transcription initiation (B. Sollner-Webb and R. H. Reeder, personal communication).

Transcription termination signals

Termination of *Xenopus* 5S RNA synthesis requires a cluster of four or more T residues in the DNA and is enhanced by an adjacent G+C-rich region[23,47,48]. These requirements have been demonstrated using mutants. A single base change (T → C), in the cluster of four T residues at which termination of 5S RNA synthesis normally occurs, allows RNA synthesis to continue past this site[10,13]. Deletions extending into the gene from the 3′ end, and thus deleting the T cluster at which termination normally occurs, prevent transcription termination, although the 3′ flanking sequence itself can be removed entirely without affecting termination[30,48]. Moreover, two yeast tRNA$^{\text{Tyr}}$ mutations which increase a string of three consecutive T residues in the middle of the gene to five or six T residues, cause premature termination within the T cluster[46]. A similar set of experiments shows that a high G+C content in the region immediately surrounding the termination site increases the efficiency of transcription termination[48]. Prokaryotic termination sequences share with 5S RNA termination sequences T clusters and G+C-rich regions, but also require dyad symmetries that are apparently not needed by the 5S RNA sequences[23,49,50].

Developmental regulation of 5S RNA synthesis

To provide for the massive synthesis of proteins during early development, there are at least 1,000 times more ribosomes in an oocyte than in a somatic cell. Two different mechanisms, selective gene expression and gene amplification, are used by the cell to enhance the rate of synthesis of ribosomal RNA (5S, 18S, 5.8S and 28S RNA) during oogenesis (see ref. 1 for review). Selective gene expression accounts for the synthesis of large amounts of 5S RNA. The 20,000 oocyte-type 5S RNA genes[51,52] per haploid chromosome set in *X. laevis* are present in all cells, but are only expressed in oocytes, where they account for >95% of the 5S RNA[17,18]. In contrast, the 18S, 5.8S and 28S RNA genes use gene amplification to synthesize large amounts of ribosomal RNA during oogenesis. *Xenopus* has 450 copies of the genes encoding these RNAs per haploid chromosome set[53,54]. Disproportionate replication[54-57] of these genes in oocytes provides extra templates for RNA synthesis, which are not used after the end of meiosis[58].

When the oocyte matures into an egg, 5S RNA synthesis stops and remains inactive until blastula formation[19,59,60]. At this point, somatic-type 5S RNA gene transcription resumes; somatic-type genes account for almost all 5S RNA synthesized throughout the rest of development. Thus, both the amount and type of 5S RNA synthesized varies during amphibian development.

Studies *in vitro* have suggested that the amount of 5S RNA gene transcription is regulated by feedback inhibition by the gene product, as 5S RNA specifically inhibits transcription of cloned 5S RNA genes[61]. The mechanism of this inhibition has been determined: 5S RNA binds to TF IIIA to form a 7S ribonucleoprotein particle, thereby competing with 5S DNA for TF IIIA[37,61,62]. As TF IIIA is essential for transcription of 5S RNA, high levels of 5S RNA inhibit its own synthesis[61]. This competition between 5S RNA and 5S DNA for TF IIIA indicates that the amount, but not necessarily the type, of 5S RNA synthesized is determined by TF IIIA.

Several models have been proposed to explain the selective expression of oocyte- and somatic-type 5S RNA genes. In one model an activator, which may be limiting for transcription in somatic cells, has a greater or exclusive affinity for somatic- compared with oocyte-type 5S RNA genes. TF IIIA has certain of the properties of such an activator: for example, it is limiting for 5S RNA synthesis in somatic cell extracts[21,22]. Moreover, the level of TF IIIA and the rate of 5S RNA synthesis are both high in immature oocytes and fall rapidly when the oocyte matures into an egg[21,22,35,37]. However, because TF IIIA has only a fourfold greater affinity for somatic- than oocyte-type 5S RNA genes[63], whereas the ratio of oocyte- to somatic-type 5S RNA changes 1,000-fold during development[64], TF IIIA is unlikely to act alone in regulating transcription. The recent discovery of a factor in somatic cells[21] which has immunological cross-reactivity with TF IIIA raised the possibility that this factor may be involved in regulating 5S RNA synthesis.

Alternatively, chromatin structure may control 5S RNA synthesis. Regions of highly condensed chromatin (heterochromatin) are normally inactive in transcription, perhaps because the DNA is not accessible to certain components of the transcriptional machinery. The 20,000 oocyte-type 5S RNA genes per haploid genome of *X. laevis* are located in blocks of ~1,000 near the telomeres of the long arm of most or all of the 18 chromosomes[65]. The telomeres are thought to be heterochromatic in somatic cells[65]; however, they may not be condensed in oocytes, where the oocyte-type 5S RNA genes are transcribed. This association of the oocyte-type 5S RNA genes with the telomeres therefore offers a possible explanation of their developmental regulation. In support of this model, *X. laevis* liver cells labelled in organ culture or kidney cells in culture, do not normally synthesize oocyte-type 5S RNA[64,66]. However, in one tissue culture cell line some 5S RNA genes are translocated to a novel site adjacent to the nucleolar organizer[65]. In this cell line, 10–20% of the 5S RNA synthesized is oocyte-type[66].

Other models for the developmental control of 5S RNA synthesis include a repressor–operator system analogous to that found in prokaryotes, and changes in the DNA methylation patterns during development. To differentiate between these models, a system is needed that mimics the regulated synthesis of 5S RNA and can be manipulated experimentally. There is no evidence of transcriptional regulation of 5S DNA purified from *Xenopus* or cloned into plasmids. When injected into *Xenopus* oocytes[10,11], or added to an *in vitro* system prepared from either oocytes[8] or somatic cells[21], both oocyte- and somatic-type 5S RNA genes are transcribed. A likely explanation is that the proteins which are normally associated with the DNA in a eukaryotic cell are absent from cloned DNA.

One study of the selective expression of oocyte and somatic 5S RNA genes during development, without using isolated DNA or cloned genes, has involved the transplantation of somatic cell nuclei into *Xenopus* oocytes[64]. When nuclei derived from erythrocytes or tissue culture cells are injected into oocytes from some frogs, they continue to synthesize somatic-type 5S RNA, but do not express the oocyte-type 5S RNA genes (Fig. 4)[64]. This finding leads to two important conclusions. First, 5S RNA genes as part of intact chromosomes behave differently from purified 5S RNA genes with respect to regulation of transcription. Second, the developmentally regulated transcription pattern of 5S RNA genes can be maintained when genes are transferred from one cell to another as part of chromosomes. In specific conditions, including treatment of nuclei with 0.35 M NaCl before injection (a condition which removes some nonhistone chromosomal proteins, but not histones), the oocyte-type genes can be reactivated[64]. Similar results have been obtained using isolated *Xenopus* chromatin[22]. The ability to manipulate 5S RNA genes in chromosomes in such a way as to alter their transcriptional capacity should provide means of identifying factors involved in controlling their expression.

Surprisingly, certain frogs have oocytes in which the oocyte-type 5S RNA genes of injected somatic nuclei are expressed (activating oocytes)[64]. When extracts from such activating oocytes are injected along with somatic nuclei into non-activating oocytes, these genes are then expressed (L.J.K. and J. B. Gurdon, unpublished results). NaCl treatment of somatic nuclei or addition of extracts from activating oocytes may exert their effect by respectively removing or adding specific factors which control 5S RNA transcription[64]. Alternatively, they may act by altering chromatin structure and in so doing influence the ability of factors already present in the cell to regulate 5S RNA synthesis. With our present understanding of the DNA sequences and factors required for accurate transcription of the *Xenopus* 5S RNA genes, and the ability to modify selectively that transcription, a complete molecular description of the developmental regulation of 5S RNA expression may be in sight.

I thank Drs D. D. Brown and J. B. Gurdon for allowing me to study the *Xenopus* 5S RNA gene system under their guidance; Drs D. F. Bogenhagen, D. D. Brown, J. B. Gurdon, F. D. Lee, D. A. Melton, P. Newmark, C. S. Parker, C. L. Queen, M. P. Wickens and R. A. Young and Ms J. Warwick for their comments and suggestions on the manuscript; and D. D. Brown, R. G. Roeder and B. Sollner-Webb for communicating results before publication. I acknowledge support of NSF grant PCM 8104522.

ARTICLES

After the deluge: Mediterranean stagnation and sapropel formation

Martine Rossignol-Strick

Wladimir Nesteroff, Philippe Olive & Colette Vergnaud-Grazzini

Département de Géologie Dynamique, Université Pierre et Marie Curie, 4 place Jussieu, 75005 Paris, France

In an East Mediterranean marine core, the upper sapropel begins soon after the start of a global event—a very heavy precipitation which occurred in the equatorial latitudes during the late Glacial–early Holocene. This heavy precipitation in Africa, channelled by the Nile River across 35° of latitude, produced a low-salinity surface layer in the East Mediterranean. In this confined basin, with high bottom salinity, the steep salinity gradient stratified the water column. The stagnant bottom waters triggered the sapropel formation. Cretaceous sapropels in the tropical oceans may result from the same chain of events in warm, humid climates, with contrasting wet-and-dry seasonal rhythm.

THE periodic sedimentation of black, pelagic muds rich in marine organic matter (sapropels) has been described extensively in Quaternary and Neogene cores of the East Mediterranean Sea[1–6].

Sapropel formation involves the establishment of a steep vertical salinity gradient in the water column, initiated by highly saline bottom waters[1] and completed by a low salinity surface layer[2,3,5,7,8], which prevents thermohaline convection and triggers a stable density stratification[1,3,4]. Stagnant bottom waters are rapidly depleted of oxygen, and this reducing environment preserves the pelagic organic matter. The epipelagic fauna is unusual in abundance, assemblage[2,7–9] and isotopic composition[5,7,10–12], the mesopelagic fauna is normal and the benthic fauna almost disappears[2,8,9,13]. Sapropels occur mostly during Quaternary warming phases, but also during some cool isotope stages[3,5,7,8,14].

As a key to stagnation control, several hypotheses on the origin of the low salinity surface layer have been formulated. The Eurasian ice-sheet meltwater hypothesis[2,3,5,11,15,16] is rejected by our ^{14}C data of the most recent sapropel, 11,760–7,950 yr BP: its flushing into the Mediterranean, through the Bosphorus, ended too early, around 13,500 yr BP (ref. 17). It may have lowered the sea surface salinity, but that did not trigger stagnation.

The local Mediterranean increased rainfall hypothesis[1,2,5], is not supported by pollen data (Fig. 1): in Greece and south-west Turkey, the warming trend started around 10,600 BP, and was probably accompanied by a small increase in moisture which became significant only after 8,200 yr BP (refs 18–20). Further south, in Crete[21], moisture increased around 9,500 and after 10,000 yr BP in Syria[22], where warming occurred at 11,500 yr BP.

0028–0836/82/020105—06$01.00

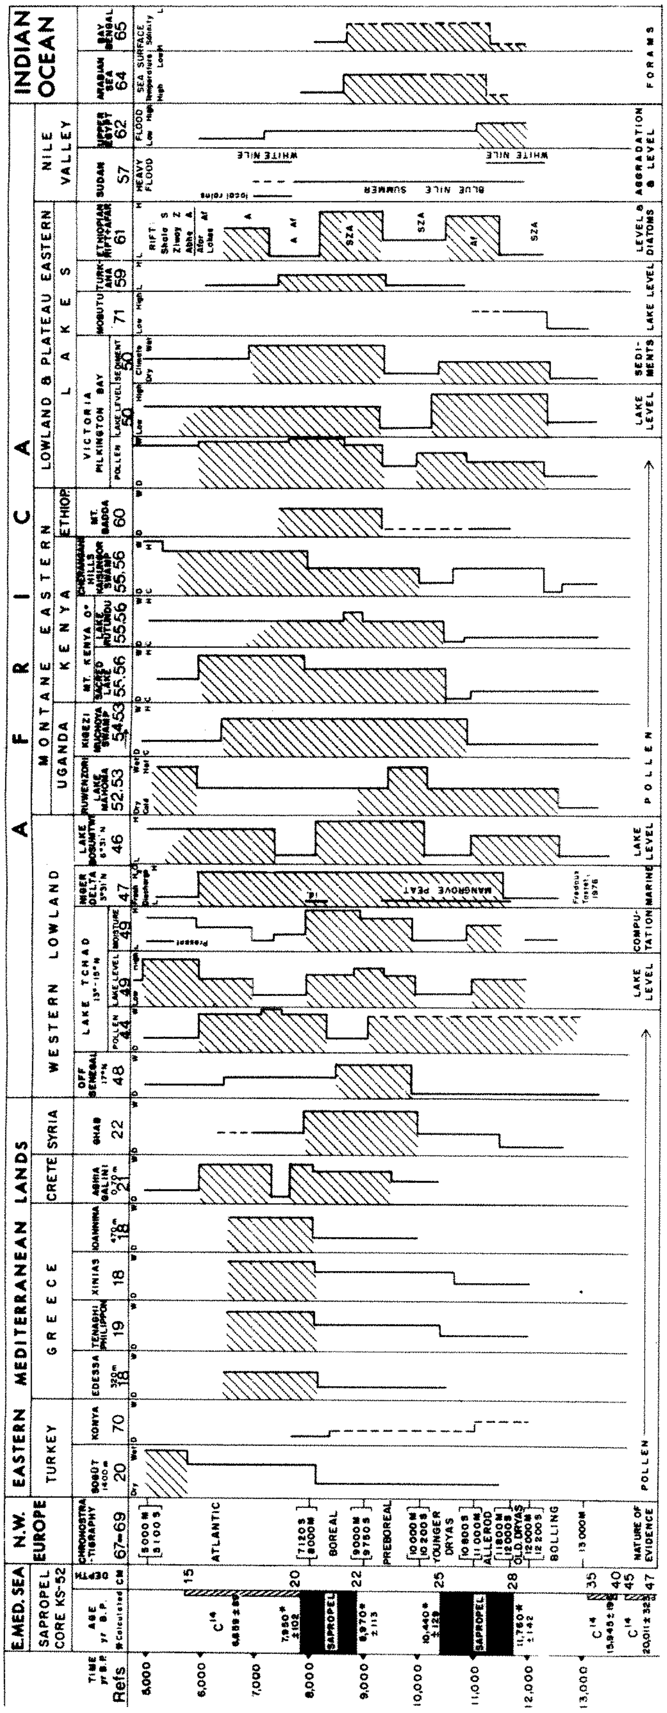

Fig. 1 Chronological setting for sapropel formation, East Mediterranean and African precipitations, Indian Ocean events. Hatched zones indicate the wettest periods.

Around 11,000 yr BP, winters had a very low insolation in the Northern Hemisphere[23], therefore it is unlikely that warmer winter temperatures might have prevented the convective sinking of the Mediterranean surface waters[2]. Downwelling now occurs in winter only in the North Adriatic Sea and around Rhodes[24]. Before stagnation, the marked contrast in seasonal insolation activated the thermohaline convection, with summer evaporation and winter downwelling.

The hydrological isolation of the deep waters in the confined East Mediterranean basin[24] progressively increased their salinity[1]. Stagnation occurred only when the surface water density became appreciably lower than the bottom water[1]. The unusual bottom fauna associated with presapropel layers reflects this increasing bottom salinity as oxygen saturation declines when salinity increases.

Precise dating of the most recent sapropel and isotopic and palynological analysis of its hydrological context suggest that it was the spreading over the sea surface of a low density, low salinity layer of great Nile River floods which triggered total deep-water stagnation. This high-nutrient discharge channelled the precipitation of a very wet period in equatorial Africa into the Mediterranean.

Dating and ^{18}O and ^{13}C isotope analysis

Core Medor 75-KS52 from the Levantine Basin (Fig. 2) (Strabo Trench, south-east of Crete, isolated from Crete by ridges, 34°00′ N–26°19′ E, water depth 3,118 m) displays the upper sapropel from 20 to 28 cm core depth. This is interrupted by a grey nanno-ooze oxygenated layer from 22 to 25 cm (ref. 13). The sapropel overlies a grey hemipelagic nanno-ooze (protosapropel) (40–28 cm) and is topped by a light brown nanno-ooze (20–0 cm).

We have established ^{14}C dates from bulk carbonates above and below the sapropel (Table 1). The absence of detrital material >63 μm does not suggest contamination by older carbonates. Since compensation occurs between the −400 yr apparent age resulting from the ^{14}C 50‰ excess in marine organisms compared with terrestrial vegetals (from the ^{13}C 25‰ enrichment of the former), and the +500 yr apparent age resulting from the ^{14}C 60‰ depletion of marine dissolved C, no correction has been applied to the measured ^{14}C age[25,26]. Assuming a constant sedimentation rate, a linear age–depth regression indicates a mean sedimentation rate between 2.0 and 2.3 cm yr^{-1}. Moreover, the isotopic stratigraphy of this core points to the rapid transition Younger Dryas–Preboreal, which took place sometime between 10,500 and 10,000 yr BP (ref. 27), at core depth 25–24 cm, precisely during the sapropel interruption.

Based on the two bracketing ^{14}C dates and the 10,000 yr BP transition, a linear interpolation yields calculated ages of the two-layered sapropel of 11,760 ± 142 to 10,440 ± 129 yr BP, and 8,970 ± 113 to 7,950 ± 102 yr BP. Although the generally accepted age has been 9,000–7,000 yr BP (refs 3, 14), our chronology is strongly supported by our isotopic stratigraphy.

^{18}O/^{16}O and ^{13}C/^{12}C ratios of the epipelagic foraminifera *Globigerinoides ruber* are presented in an unprecedently tight sampling of 34 levels in 50 cm of core length in Fig. 3. Oxygen isotopic compositions decrease overall by 3.75‰, from about 17,000 yr BP (40 cm core depth), through several large shifts, to minimal values reached between 8,000 and 6,000 yr BP (21–17 cm). This 3.75‰ decrease ought to correspond to the Termination I continental warming and melting of the northern ice sheet. However, it occurs here over 9,000–11,000 yr, which is much too long. Moreover, it displays three main phases:

(1) A stepwise decrease averaging 2‰ between 40 and 28 cm (17,000–11,800 yr BP) before sapropel deposition (at 28 cm) but including several sharp oscillations of about 1‰ amplitude after 14,000 yr BP. The very high, sharp depletion peak at 28 cm, is 1.5‰ higher than the previous average level, immediately before the beginning of sapropel.

(2) From around 11,000 yr BP to around 10,000 yr BP, a return to values slightly higher than at 17,000 yr BP. They

Table 1 Upper sapropel ^{14}C dates in Mediterranean cores

Ref.	Core	Sediment	Depth (cm)	Age (^{14}C yr BP)
72	Alb-194	Sapropel mud	9–17	8,330 ± 130
73	V10-64	Carbonate in sapropel:	23.5–28.5	
		coarse fraction		8,700 ± 1,000
		fine fraction		7,400 ± 200
		organic matter		8,400 ± 250
74	24M067	Sapropel		7,900 ± 170
75	OT 26	Varved layer	174–178	8,210 ± 185
	OT 25	Under finely laminated layer	core basis	9,640 ± 150
14	P6510-4	Organic ooze above sapropel	21–28	6,575 ± 160
		Sapropel (50–63 cm)	51–60	8,215 ± 160
		Hemipelagic mud below	101–110	10,475 ± 140
This work	KS 52	Nanno-ooze above sapropel-S1	15–20	6,659 ± 89 CRG 97
		Nanno-ooze below sapropel-S1	35–40	15,945 ± 196 CRG 98
		Nanno-ooze	45–47	20,011 ± 323 CRG 99

appear during sapropel deposition and precede ~600 yr the deposition of the intercalated oxygenated ooze, during which the maximum $\delta\ ^{18}$O is reached. This interval of high values is synchronous with the Younger Dryas cold event (11,160–10,000 yr BP).

(3) A second large, rapid decrease of 3.75‰ before deposition of the younger part of the sapropel, until minimal values are reached between 8,000 and 6,000 yr BP. A subsequent increase of ~1.4‰ leads to present day (average) values, which appear in the upper 10 cm.

^{13}C depletions correlate with minimal $\delta\ ^{18}$O values at 28.5 and 23.5 cm, but this species displays a rather strong non-equilibrium fractionation[28].

Palaeoclimatic implications

The East Mediterranean basin thus experienced a slow and complicated isotopic transition from glacial stage 2 to postglacial stage 1. The overall 3.75‰ $\delta\ ^{18}$O variation is more than double the 1.7‰ normal difference between glacial stage 2 and present-day values. The 2.05‰ additional difference is too large to signal only a temperature increase, which would be an excessive +10 °C. A 2–3 °C increase is generally accepted in the Mediterranean during Termination I[5,8], accounting for a $\delta\ ^{18}$O of −0.7‰. The remaining 1.35‰ has to be accounted for by fresh water influx forming a low salinity surface layer[5,7,10,11].

Moreover, both ^{13}C and ^{18}O isotope depletions occur rapidly before sapropel deposition. A simple calculation shows that the isotopic composition of the fresh water entering the Mediterranean has to be higher than −10‰. This low estimate suggests that precipitation and river discharge are the dominant source of the surface brackish water layer, and not ice sheet meltwater, which would have an isotopic composition around −30‰. River floods started around 12,500 yr BP (second half of the first decrease), waned around 11,000 yr BP, and reappeared immediately after 10,000 yr BP.

The earliest 2.5‰ $\delta\ ^{18}$O decrease (45–30 cm), dated 20,000–12,600 yr BP, is accounted for by three elements: part of the 1.7‰ global isotopic effect, the 2–3 °C temperature rise, and some salinity decrease due, until 13,500 yr BP, to meltwater influx through the Bosphorus. Partial stagnation developed, resulting in the grey protosapropel layers. Sapropel formation was triggered, after a 230-yr time lag, by the second, sharp, highest 1.5‰ $\delta\ ^{18}$O depletion, (30–28 cm) between 12,600 and 11,700 yr BP, entirely a salinity effect due to heavy floods.

The Nile River is the only contender for such a discharge. Before the Aswan High Dam construction, Nile flood water was partly carried eastward along the Israeli coast, where it flowed as a 15-m thick surface layer, decreasing the salinity from its normal values of 38.8‰ to 31.80‰ in September[29]. Local rainfall from December to March decreases the salinity only to 36‰ (ref. 30). The Nile flood does not seem to exert a temperature effect[30]. Present-day mean weighted isotopic values of precipitation at Entebbe, Uganda, is −2.91‰ (ref. 31). The freshwater discharge becomes brackish when mixed by winds, currents and internal waves with the seawater. The Nile origin of the brackish surface layer accounts for the frequently observed east–west gradient of decreasing stagnation and surface productivity in the sapropels. A 10% decrease (from 38‰ to 34–35‰) of the surface salinity is sufficient to induce water stratification. Today, stable stratification is observed seasonally in the open tropical oceans where the freshwater discharge of large rivers spreads as a brackish surface layer (<50 m deep), sometimes as far as several hundred kilometres. Stratification from monsoonal discharge occurs in the Andaman Sea, caused by the Irrawady[32], off the West Coast of India with the runoff from the Ghats[33], and from non-monsoonal (zenithal) discharge, in the West Equatorial Atlantic under the influence of the enormous Amazon flow, which sends isolated lenses of brackish water as far as Barbados[34]. In all these cases, a 2–4‰ vertical salinity gradient in the upper 50 m is responsible for the density stratification, whereas the generally warm temperature has little effect on the pycnocline.

The present day Amazon discharge (75 times the Nile), would cover the entire Mediterranean Sea with a 3-m deep freshwater layer in one year[34]. If the late Glacial Nile discharge was 2.5 times larger than today, like the present Zambeze, it could have accumulated a 25-m deep freshwater surface layer over the Levantine and Ionian basins in only 15 yr. The lags we see in the core between the two sets of heavy floods and sapropel incipience are 230 and 800 yr.

The very rapid 3‰ $\delta\ ^{18}$O increase from 28 to 26.5 cm (11,000–10,000 yr BP) is a result of the cumulative effects of the Younger Dryas glacial buildup, the colder temperatures, and the dramatic decrease of Nile floods, resulting from the simultaneous period of aridity in equatorial Africa. This arid episode is clearly seen in many African low lake levels and pollen diagrams (Fig. 1). It occurred even though the very high incoming summer insolation[23] could have been expected to promote heavy tropical rainfall. The insolation effect in this case is overrun by the atmospheric cooling of high-latitude origin. Colder temperatures in the Mediterranean area are reflected in the Macedonian pollen diagram (zone Y3)[19].

The sharp 3‰ $\delta\ ^{18}$O depletion from 24.5 to 23.8 cm took place in about 300 yr. It is much too large and rapid to be caused solely by ice melt and warming of the Younger Dryas–Preboreal transition[27]. It signals a salinity lowering due to resumption of heavy Nile floods after 10,000 yr BP. They correlate with the African main rainy period from 10,000 to 8,000 yr BP which builds the highest lake levels around 9,500 yr BP (Fig. 1).

The second half of the sapropel is a consequence of these floods. The time lag between the high floods and sapropel incipience is ~800 yr, which is much longer than the previous one, because the floods discharged over a much more saline sea surface.

In the shallower East Mediterranean core GA32, the bottom-to-surface $\delta\ ^{18}$O gradient increases suddenly at two levels, suggesting a two-step flooding sequence[12]. The isotopic variation related to salinity change is also 1–1.5‰ here.

Although high nutrient input and planktonic productivity are associated today with the arrival in September of the tongue of Nile flood water off the Israeli coast[30,31,35], one should not argue that the low ^{13}C/^{12}C ratios in surface waters are caused by a higher nutrient input. (Each plankton net haul yields 3 cm^3 of

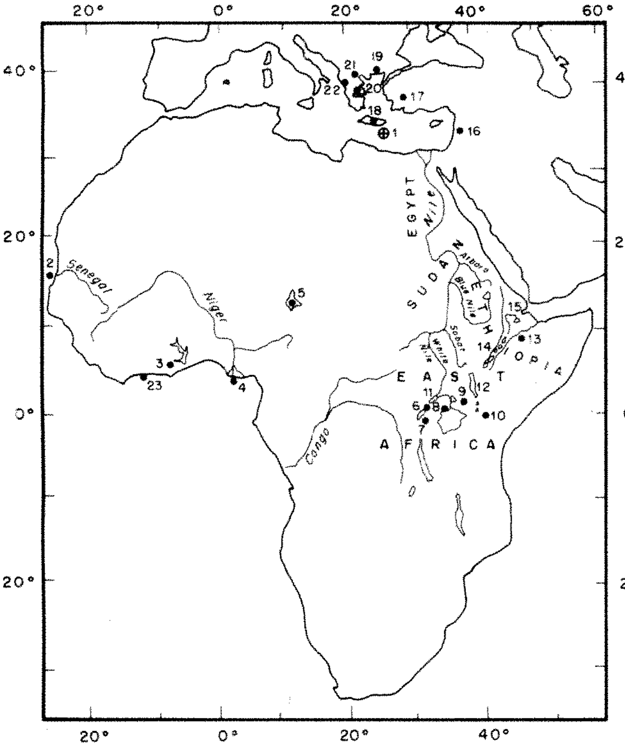

Fig. 2 Location of core and mentioned sites. 1, Core KS52. 2, Core off the Senegal River mouth. 3, Lake Bosumtwi, Ghana. 4, Core off the Niger River mouth. 5, Lake Tchad. 6, Ruwenzori, Lake Mahoma. 7, SW Uganda, Muchoya Swamp. 8, Lake Victoria, Pilkington Bay. 9, Cherangani Hills. 10, Mt Kenya, Sacred Lake, Lake Rutundu. 11, Lake Mobutu Sese Seko (Albert). 12, Lake Turkana (Rudolf). 13, Mt Badda. 14, Ethiopian Rift Lakes. 15, Afar Lakes. 16, Ghab Valley, Syria. 17, Sogüt, Anatolia. 18, Aghia Gallini, Crete. 19, Tenaghi Philippon, Macedonia. 20, Xinias Lake. 21, Edessa. 22, Ioannina. 23, Ivory Coast littoral.

plankton in August, 30–35 cm^3 in September; the yearly average is 4.7 cm^3 and the spring bloom reaches only 12.5 cm^3 (ref. 31).) In the Indian Ocean, the δ ^{13}C of shallow dwelling foraminifera is not related to nutrient supply of upwelling origin[36]. High primary productivity might even be the cause of a higher δ ^{13}C of the ΣCO_2 at the same depths (J. C. Duplessy, personal communication). Thus, the depletion we measure in core KS52 are related to the influx of organic rich freshwaters (with a low ^{13}C/^{12}C ratio of the ΣCO_2) of continental origin. These low surface ratios result in an intense vertical δ ^{13}C gradient in the water column.

Pollen

The upper sapropel pollen spectrum (pollen sum 356) (around 9,500 yr BP) predominantly reflects a Mediterranean (48.2%) and warm temperate (6.5%) vegetation. It is very similar to the earliest Holocene in Macedonia (Zones Z1 and 2, 10,300–9,000 yr BP)[19]. An open (herbaceous: 45.4%) oak (31.1%) pine (15.1%) forest occupied the Greek and Turkish Mediterranean shores, and broad-leaved trees (6.5%) requiring more summer moisture grew higher on the slopes. Littoral or desert halophytes (11.1%) were more abundant here than in Macedonia. The cold steppe *Artemisia* is hardly present (6.0%). The pollen is transported by wind to the sea surface, then dispersed by currents as a pelagic element[37]. Well specified Nilotic pollen[38] is absent: the Nile water does not appear to carry pollen further than its sedimentary load; they are only found in Nile silt[38]. The low density characteristic of the Nile water is thus preserved far beyond the silt and pollen deposition limits. The geological implication is that bottom waters in a deep or shallow basin may become anoxic under the influence of fluvial discharge even if the local climate reflected by pollen cannot feed such rivers, and even where clastic sediments do not reach. In fact, bottom anoxicity may occur whatever the lithology of the depositing sediment, provided distance from the continent is not too great. Moreover, this limiting factor can be enlarged in a globally warm climate like the Cretaceous, during which weak winds and sluggish ocean currents do not enhance water mixing.

Late Glacial–early Holocene equatorial deluge

During the last Glacial maximum (19,000–13,000 yr BP), extreme aridity spread in the tropics. It was immediately followed, during the late Glacial–early Holocene (Alleröd–Preboreal–Boreal), by an equatorial heavy rainfall period of global scale, recorded by pollen, in northern South America (Guantiva Interstadial)[39], the Galapagos[40,41], most probably New Guinea[42], with extensive wet Lower Montane *Nothofagus* forest, Sumatra[43], and the Indian Ocean and Africa. Raised lake levels are also conspicuous. It was the wettest period of the past 20,000 yr.

The formation of the Mediterranean sapropel results from a link (the Nile River) across 35° lat. between this climatic event in equatorial Africa and the marine hydrology. The relevant data are shown in Fig. 1.

In Africa, from west to east, and within 10° N of the Equator, the highest precipitation is recorded between 12,500 and 8,000 yr BP. In West Africa, data are from the southern drainage area of Lake Tchad[44], the Ivory Coast mangrove peat[45], the level of Lake Bosumtwi in Ghana[46], and the Niger River discharge[47]. North of 10° N, the onset of the rainy period is delayed. The mangrove along the Senegal River lower course (17° N) thrives after 9,600 yr BP (ref. 48), and the high level of Lake Tchad (13–15° N)[49] and its wettest vegetation[44] occur after 8,500 yr BP.

In East Africa, where the Nile watershed is situated, reinterpreted pollen data from the mountains, 3 °S–2 °N, correlate aridity before 12,000 yr BP with a cool climate, and moisture thereafter with a warm climate[50,51]. On the Ugandan (Ruwenzori, Kigezi[52–54]) and Kenyan (Mt Kenya, Cherangani Hills[55,56]) mountains, the shift towards a wetter and warmer vegetation

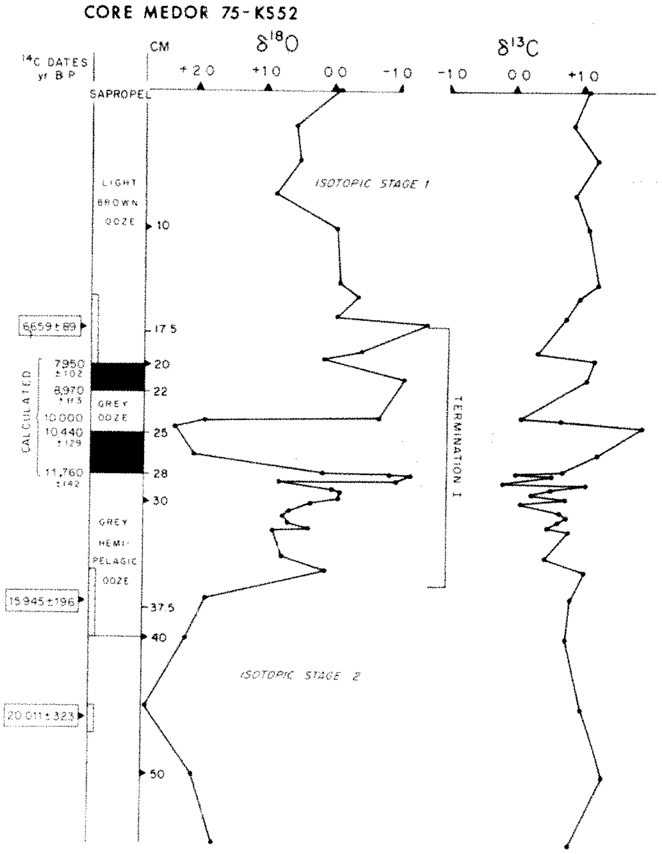

Fig. 3 Sapropel age, ^{18}O and ^{13}C isotopes stratigraphy in core KS52.

belt, of different types according to the altitude of the site, started as early as 12,700 yr BP and developed around 10,800 yr BP. The warmest and wettest local vegetation is usually installed around 8,000 yr BP.

In the lowlands around Lake Victoria, the moisture increased after 12,500 yr BP, and the wettest climate is signalled between 9,500 and 7,000 yr BP by the vegetation, the lake level and its sediments[50]. A widespread dry spell, synchronous with the Younger Dryas, is recorded between 10,800 and 9,500 yr BP in the low levels of Lakes Bosumtwi, Tchad and Victoria, as well as in the vegetation around Lake Victoria and on Mt Kenya.

Before 12,000 yr BP, the Main Nile was dry most of the year, the meagre summer flow fed only by the weak Ethiopian monsoon. After 12,000 yr BP, the East African bi-seasonal rainfall was higher and the White Nile became a very large permanent river, well regulated by the lakes[51,57,58]. Its catchment area was expanded from 9,500 to 7,500 yr BP by the inclusion of the much higher, larger Lake Turkana[59].

Wetter conditions occurred on the southeastern Ethiopian Plateau at Mt Badda, after 11,500 yr BP or possibly only 9,500 yr BP (ref. 60).

Drained by the Blue Nile and the Atbara, the northern Ethiopian Highlands (10–13° N) are inaccessible, but their palaeoclimate is documented by the peripheral Rift and Afar Lakes[61]. The lake levels were highest, much above today, and they merged between 9,500 and 8,500 yr BP. The Ethiopian summer flood of the Nile was therefore much heavier. This seasonal variation accounts for the lamination of the sapropels: the white laminae are formed by coccoliths[14] blooming with the flood, rich in dissolved ions of Ethiopian basalt origin.

The Nile Valley aggradation records these floods mostly from 12,000 to 11,000 yr BP, and from 8,000 to 7,000 yr BP in Sudan and Upper Egypt[57,58,62]. There, aggradation indicates a "wild Nile with aberrant summer floods of a phenomenal volume"[62]. Moreover, higher local Sudanese (15° N) rainfall, which may have reached 550 mm yr^{-1} (163 today)[63], between 8,000 and 7,000 yr BP (ref. 57), suggests decreased evaporation along the course of the Nile. Today, evaporation in the Sudanese swamps heavily reduces the Nile discharge.

The African and Indian monsoons, of equatorial westerlies origin, both controlled by the continental heat trough, displayed the same peak when the summer insolation was higher than today around 11,000 yr BP. At that time, strong monsoonal air flow and high rainfall in India is suggested by low sea-surface summer temperature in the Arabian Sea[64], due to strong upwelling induced by the southwesterly air flow, a mangrove much more extensive than today on the Indian coast near Bombay (E. Van Campo, personal communication), and river discharge higher than today in the Bay of Bengal[65]. The Intertropical Convergence of the tropical easterlies, with its zenithal rains, was reactivated in East equatorial Africa.

From the eastern tropical Atlantic to the Bay of Bengal, along the inner tropics of the African continent and Indian Ocean, and in the other equatorial longitudes, as the summer insolation was highest, the late Glacial–early Holocene was a very wet period, the most humid of the past 20,000 yr. From around 12,500 yr BP, during the Bolling–Alleröd interstadial, the higher rainfall belt migrated progressively from the Equator polewards through the Preboreal and Boreal. The Atlantic was the wettest period in the 50–55° N lat. zone. It was set back by a drier episode which corresponds to the cold Younger Dryas, recorded in the Mediterranean sapropel by the disappearance of the brackish surface layer, thus interrupting the stagnation from 10,400 to 9,000 yr BP.

Conclusion

The Mediterranean two-layered upper sapropel in core KS52 is dated at 11,800–10,400 yr BP and 9,000–8,000 yr BP, the interruption resulting from the Younger Dryas cold/dry event. This is too late to be caused by the influx of Eurasian ice-sheet meltwater. Instead, oxygen and carbon isotope variations in planktonic foraminifera show that the light, low-salinity, organic and nutrient rich sea-surface layer which spread slightly before sapropel deposition and selectively increased the planktonic productivity, originated as rainfall. The pollen record around the eastern Mediterranean does not indicate much increased local rainfall at that time. Meanwhile, in equatorial Africa, very heavy rainfall began at 12,500 yr BP and culminated between 10,000 and 8,000 yr BP. We conclude that this equatorial deluge, channelled by the Nile River over 6,700 km is, as already suggested[58,66], the source of the surface brackish-water layer in the Mediterranean. This layer enhanced the vertical salinity and density gradient, and established stable stratification. Thus bottom stagnation was triggered in this hydrographically restricted deep basin, and sapropel formation resulted. The East Mediterranean behaved as an ectogenic meromictic lake as a stratified estuary and as a fjord during the stagnation events.

The establishment of these climate links have far-reaching geological implications.

(1) The Quaternary climatic chronology of Africa is recorded in the eastern Mediterranean subsurface. Sapropels are formed during all the periods of high summer insolation of the Northern Hemisphere displayed by the Milankovitch curve, which occur even during glacial isotopic stages 3, 4 and 6. The isotope stratigraphy supports these correlations.

(2) Widespread marine stagnation events occurred during certain short and well-defined periods of the Cretaceous. They deposited pelagic laminated sapropels and we suggest that they result from the same chain of events as this recent Mediterranean sapropel. In equatorial West Gondwana around the opening Atlantic, the thick fluvio-deltaic sediments of the Barreirinhas Basin suggest great river discharge in a seasonally very humid tropical climate, with a contrasting dry season enhancing evaporation. These Cretaceous sapropels may be important as possible petroleum generating environments.

Polyoma virus capsid structure at 22.5 Å resolution

I. Rayment, T. S. Baker & D. L. D. Caspar

Rosenstiel Basic Medical Sciences Research Center, Brandeis University, Waltham, Massachusetts 02254, USA

W. T. Murakami

Department of Biochemistry, Brandeis University, Waltham, Massachusetts 02254, USA

X-ray diffraction data from polyoma capsid crystals were phased by refinement of low-resolution starting models to obtain a self-consistent structural solution. The unexpected result that the hexavalent morphological unit is a pentamer shows that specificity of bonding is not conserved among the protein subunits in the icosahedrally symmetric capsid.

X-RAY crystallographic studies on polyoma virus were begun to visualize the protein subunit packing in the icosahedral capsid and to explore the way in which the chromatin core of this tumorigenic virus is packaged inside its protein shell[1]. Analysis of electron micrographs has established that the capsid consists of 12 five-coordinated and 60 six-coordinated morphological units[2] (capsomeres) arranged on a $T = 7d$ icosahedral surface lattice[3] (Fig. 1). It has been presumed, based on the principles formulated to account for the morphology and chemical composition of simple icosahedral virus particles[4], that the capsids of the $T = 7$ papova viruses should be constructed from 420 identical protein subunits quasi-equivalently bonded into 12 pentameric and 60 hexameric capsomeres. High-resolution X-ray structure determination of tomato bushy stunt virus[5] and southern bean mosaic virus[6] has established that quasi-equivalence is used to conserve essential bonding specificity among the 180 chemically identical subunits of these $T = 3$ icosahedral capsids. Our 22.5-Å resolution electron density map of the polyoma capsid reveals unexpected substructure in the hexavalent capsomere that is inconsistent with the expectation of quasi-equivalent bonding of identical subunits. (The adjectives 'hexavalent' and 'pentavalent' are introduced to identify the six- and five-coordinated morphological units without prejudging the nature of their substructure.)

The starting point for our analysis of the polyoma capsid diffraction data was a model representing the coarse surface features seen in the three-dimensional image reconstruction from electron micrographs of negatively stained particles[3]. The capsomeres in this image reconstruction appear as hollow, stubby protrusions with no regular substructure, about 50 Å in diameter and separated from their nearest neighbours by 80–90 Å at a radius of 200 Å in the capsid. Pentavalent and hexavalent morphological units appear to be about the same size, which would not be expected if they were composed of pentamers and hexamers of identical protein subunits.

Cells infected with polyoma virus and other papova viruses produce, in addition to intact virions and empty capsids, hollow tubular particles that appear to be polymorphic assemblies of the capsomeres[7]. There are two categories of tube: wide tubes,

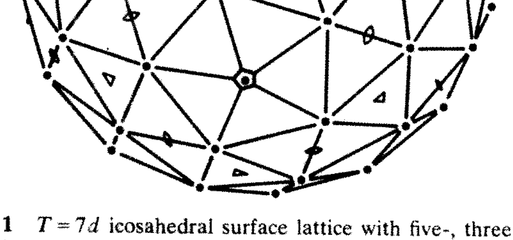

Fig. 1 $T = 7d$ icosahedral surface lattice with five-, three- and two-fold axes marked. The drawing shows one side of the polyhedral surface consisting of 60 six-coordinated and 12 five-coordinated lattice points at the same radius. The location of the six-coordinated point is that determined for the hexavalent morphological unit in the polyoma capsid.

0028-0836/82/020110—06$01.00

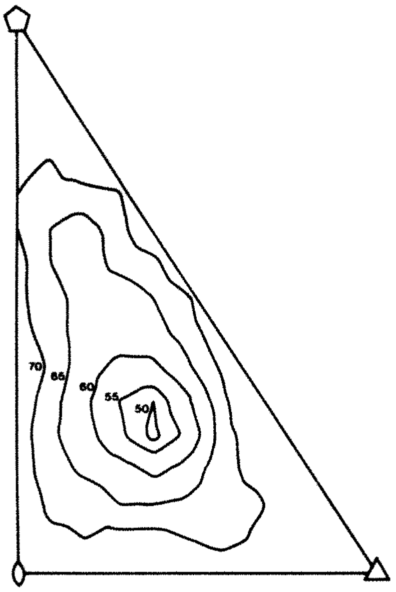

Fig. 2 Location of the hexavalent unit in the icosahedral surface lattice. The R factor comparing the calculated and measured diffraction pattern is plotted as a function of the position of the hexavalent unit in the icosahedral cell defined by the five-, three- and two-fold axes (see Fig. 1). The model giving the smallest R factor is shown in Fig. 3*a*.

about the diameter of the virion, which are built of capsomeres arranged in a hexagonal surface lattice, and narrow tubes, which Kislev and Klug[8] showed to be constructed of pentameric capsomeres arranged in a lattice they called a 'pentagonal tessellation'. The capsomeres of the wide tubes were presumed to be hexamers but the chemical and structural relationships between the morphological units of the 'hexamer' and 'pentamer' tubes could not be established at that time. In the light of our results new questions are raised about the structure of these polymorphic assemblies of the capsid subunits.

Complete virions contain seven different proteins, four of which are cellular histones associated with the DNA, the other three (VP1, VP2 and VP3) being virus coded[9]. VP1 (molecular weight (MW) ~42,000) is the major capsid protein. The function of VP2 and VP3 (MW ~ 35,000 and ~23,000, respectively), which constitute less than 20% of the virion proteins, is not clear. Purified capsids have been prepared that contain only VP1[10] and these particles have normal morphology. Thus, the pentavalent and hexavalent capsomeres seem to be built of identical VP1 subunits.

Crystallography

Polyoma virus capsids of the strain Sp-34 were isolated as previously described[11]. The preparation used for growing crystals consisted predominantly of the major capsid protein, VP1, and only a small amount of VP2 and VP3 compared with the intact virion. Crystals, in the rhombic dodecahedral form[12], were grown by equilibrating a solution of polyoma virus capsids at 4 mg ml^{-1} in 0.02 M Tris *p*H 9.5 and 0.17 M sodium sulphate against 0.55 M sodium sulphate by vapour diffusion. Crystals grew over a period of 1 month at room temperature. These crystals diffracted to a resolution of at least 8 Å. The icosahedral capsids, of packing diameter 495 Å, are located at the centre and corners of the b.c.c. lattice (space group I23, unit cell edge 572 Å) with particle two- and three-fold axes coincident with the crystallographic axes[1]. Diffraction data were collected to 22.5 Å resolution by screened precession photography (crystal-to-film distance 150 mm) with an Elliott GX6 rotating anode X-ray generator using a 0.2-mm focal cup and two perpendicular-focusing mirrors[13]. A total of 11 zero level ($\mu = 2°$) and 4 upper level ($\mu = 1.5°$) photographs were collected, each a 48-h exposure. These gave 1,481 independent reflections between (1/150) and (1/22.5) Å spacing, representing 94% of the data within this resolution range. The individual films were digitized on an Optronics P1000 densitometer at 50 μm scanning raster and processed using a modified version of the Harvard Scan-11 system on a PDP-11/40 computer. The films scaled together with an R factor measuring the mean variation in intensity of symmetry-related reflections of 5.7%.

Models for phase refinement

Trial phases, calculated to 30 Å resolution from models based on information from electron microscopy[3] and small-angle X-ray diffraction[1], were refined and extended to 22.5 Å resolution by imposing the constraints of non-crystallographic symmetry and solvent flattening. This approach is similar to that used to determine the structure of southern bean mosaic virus to 22.5 Å resolution[14]. Our starting model of the polyoma capsid, consisting of 72 morphological units arranged in a $T = 7d$ icosahedral surface lattice (Fig. 1), is a non-centrosymmetric structure. Consequently, calculated trial phases will introduce the non-centric component of the structure factors from the start. This is essential to the quality of the subsequent real-space phase refinement and extension.

Models consisting of 72 hollow cylindrical capsomeres on a spherical shell were formulated with 9 adjustable parameters defining the size and position of the structural elements. Phases from these models were calculated by Fourier transforming a density map generated in a lattice corresponding to the polyoma crystal. The model parameters were adjusted by comparing the calculated and observed structure factor amplitudes. The models which gave the best R factor fit were built from morphological units about 40 Å high and 80 Å in diameter with a 35-Å diameter axial hole, resting on a shell extending from a radius of 180–200 Å. The effect of moving the hexavalent morphological unit in this model is shown in Fig. 2, where the R factor is plotted as a function of position. The position of the minimum is close to the hexavalent capsomere location observed in Finch's image reconstruction from electron micrographs[3]. A projection of this 'best' model down a two-fold axis is shown in Fig. 3*a*. The R factor for this model to 30 Å resolution was 50% where R is defined as

$$R = \frac{\sum ||F_o| - |F_c||}{\sum |F_o|} \times 100$$

where $|F_o|$ and $|F_c|$ are observed and calculated structure factor amplitudes. The R factor as a function of resolution is shown in Fig. 4*a*.

Particle envelope

Flattening the solvent regions of the electron density map places a powerful constraint on the low resolution phases and also provides the basis for phase extension. Thus, the envelope chosen to enclose the virus capsid is critical in the phase refinement and extension. The envelope used was a spherical shell extending from 165 Å to 260 Å truncated by planes perpendicular to the icosahedral three-fold axes 247 Å from the virus centre. These boundary planes bisect the line of contact between virus particles along the crystallographic three-fold axes. The three hexavalent units adjacent to the crystallographic three-fold axis make contact tip to tip with the related set on the neighbouring particle. As there is no discernible interdigitation of the capsomeres at this resolution, the boundary planes perpendicular to the three-fold axes define the volume associated with one virus particle.

Solvent density for both the interior and exterior of the capsid was taken as the average observed density of the shell extending from 160 to 165 Å. This approach was used because omitting unmeasured low-resolution <(1/150) Å reflections in the initial calculations results in spurious electron density ripples inside the capsid. When the average density of the total solvent region defined by the particle envelope was used as suggested by Bricogne[15], the refinement calculation converged more slowly. Nevertheless, both methods of determining the solvent density gave very similar final values.

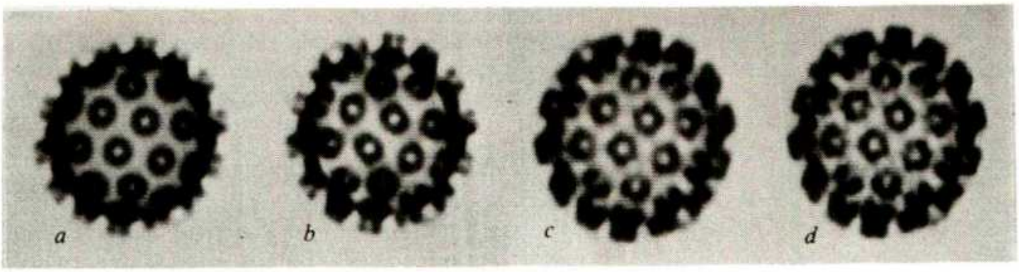

Fig. 3 Density maps of the top half of particles (diameter 495 Å) projected down a two-fold axis (orientation as in Fig. 1). The maps were scaled to have the same total electron density and were photographed directly from a 256 grey scale TV graphics display. *a*, Model map at 30 Å resolution; *b*, map computed using observed data and model phases to 30 Å resolution without refinement; *c*, 30 Å resolution refined map; *d*, refined map at 22.5 Å resolution calculated by phase extension from 30 Å. Note how the substructure in the morphological units develops as the refinement proceeds. Even at 30 Å resolution the hexavalent unit has a pentagonal appearance.

Refinement method

The calculated phases from the model structures were refined to 30 Å resolution against the observed structure factor amplitudes by imposing the constraints of solvent flattening and the five-fold non-crystallographic symmetry[15–17]. An electron density map was calculated to 30 Å resolution using the model phases and observed amplitudes, and averaged over the five non-crystallographic asymmetric units within the particle envelope. The observed amplitudes were weighted according to their fit to those calculated from the model according to the scheme

$$W = \exp\left(-\frac{|F_o| - |F_c|}{|F_o|}\right)$$

This simple weighting scheme gave faster convergence than that suggested by Sim[18], but the final phase set was not sensitive to the weighting procedure used.

The averaged, solvent-flattened density map was Fourier transformed to calculate phases and amplitudes for the first cycle of refinement; the r.m.s. phase difference and R factor comparing initial and refined structure factors were evaluated; refined phases were combined with measured amplitudes to initiate the next cycle of refinement; these calculations were iterated until the calculated phase difference and R factor did not change significantly from one cycle to the next.

There are two possible orientations for the icosahedral five-fold axis in the I23 unit cell. The orientation used was that indicated by the intensity spikes in the diffraction patterns[1]. If the alternative orientation of the five-fold axis was chosen, the R factor between refined and observed structure factors never dropped below 50%. The standard deviation in the density between the five icosahedral units in the crystallographic asymmetric unit for the correct orientation was 1/7th of that calculated for the alternative.

Omission of the unmeasured data below (1/150) Å spacing systematically lowers the calculated amplitudes for the observed structure factors below (1/100) Å spacing. The amplitudes of the innermost observed reflections are the largest in the data set and dominate the scaling of the calculated to the observed structure factors. This effect was mitigated by including the calculated values for the unmeasured data after the fourth cycle with a weight of 0.9. Reduced weighting was applied to avoid divergence of these large terms in the iterative refinement. Various test calculations have established that the low order data can be accurately estimated from the higher resolution data. Without the eight calculated values for the missing low order data, the refinement converged to only 27% as compared with 10.5% with these data after 14 cycles of phase refinement.

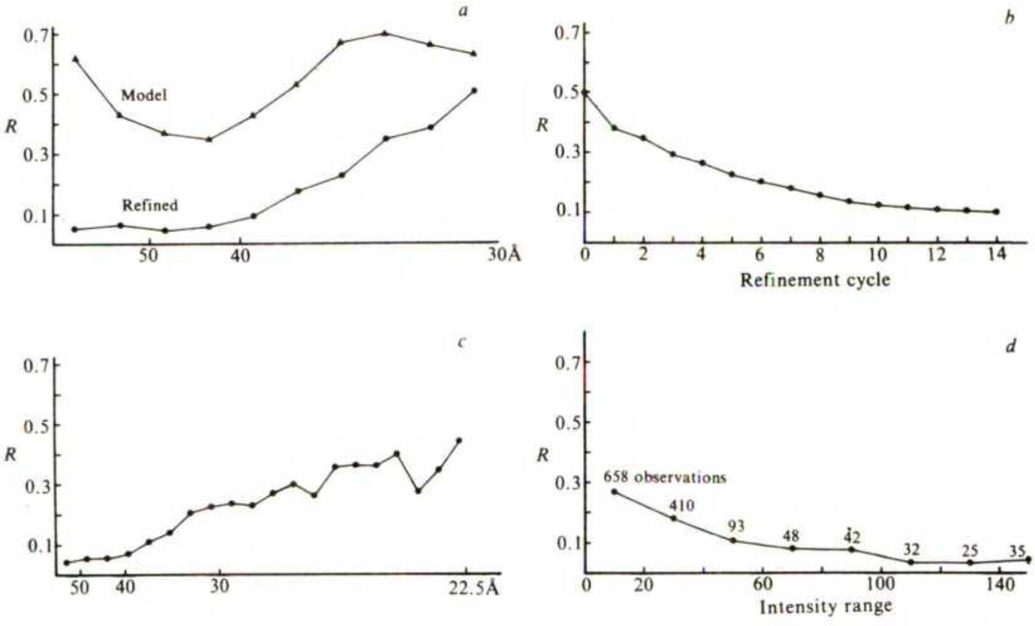

Fig. 4 R factors comparing the agreement between observed and calculated structure factor amplitudes. *a*, As a function of resolution comparing initial model and refined map at 30 Å resolution; *b*, as a function of refinement cycle at 30 Å resolution; *c*, as a function of resolution for the phase extension from 30 to 22.5 Å resolution; *d*, as a function of intensity for the 22.5 Å refined map. For *a* and *c* the points are plotted so that the interval between points corresponds to equal volume increments in reciprocal space. The starting model (Fig. 3*a*) fits the observed data best in the 40–50 Å resolution range where there is a strong modulation in the transform determined by the surface lattice arrangement of the morphological units[1]. After 14 cycles of refinement (*b*) there is a substantial improvement in the fit between the calculated and observed amplitudes at low resolution (*a*). The structure amplitudes phased by extension from 30 to 22.5 Å resolution represent over half of the total data to this resolution. The R factors for these higher resolution data (*c*) are uniformly satisfactory. The phase extension also leads to an improvement in the R factor for the data to 30 Å resolution by reducing series termination effects. Plotting the R factor of the 1,343 non-zero reflections as a function of intensity (*d*) shows that there is a correlation between the R factors and the accuracy of the data which are more precise for the stronger reflections.

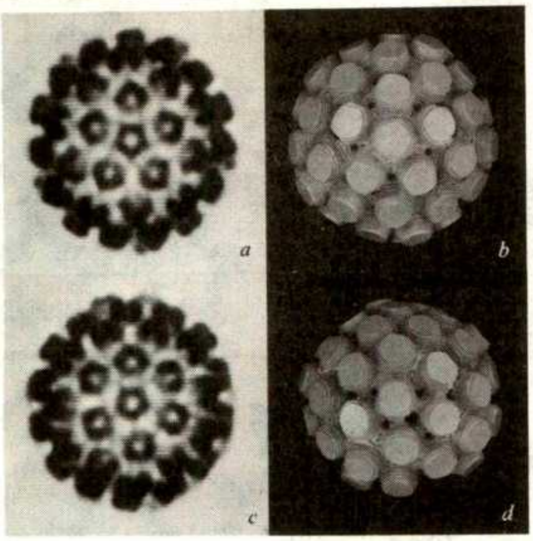

Fig. 5 Views of half the capsid (495 Å diameter) down the five-fold axis (*a*, *b*) and down the axis of the hexavalent unit (*c*, *d*). *a* And *c* are computer graphics projections of the electron density map at 22.5 Å resolution, *b* and *c* are photographs of a model of stacked sections of the map at 30 Å resolution with the external contour level set at 0.2 of the maximum density. The half-model was built symmetric about the five-fold axis (*b*), thus, when it is tilted to view down the hexavalent unit (*d*) the bottom portion of the image is incomplete.

Figures 3*a–c* and 4*b* illustrate the progress of the refinement in real and reciprocal space. Figure 4*b* shows the *R* factors as a function of refinement cycle. Figure 3*a* represents the starting model to 30 Å resolution, Fig. 3*b* the unrefined structure calculated from the observed amplitudes with model phases, and Fig. 3*c* the refined structure at 30 Å resolution.

Tests of refinement method

There is no established criterion for determining the correctness of the electron density map described subsequently. Because the map shows unexpected features, considerable effort was devoted to demonstrate the uniqueness of the refinement. Phases from any model consisting of 72 bumps distributed on the surface of a spherical shell, in a manner consistent with the image from electron microscopy[3], refined to the same solution. Indeed, a starting model which placed 60 hemispheres close to the location of the hexavalent units on a spherical shell with no density protruding on the five-fold axes (initial *R* factor = 65%) refined to the same phase set as the more realistic models, although it took 18 cycles of refinement. Furthermore, phases from elaborate models with hexavalent morphological units containing either five- or six-fold substructure refined to the same final structure.

The reliability of the refinement method was tested by using amplitudes calculated from models in place of observed data. Because the model structure factor calculations give both the amplitude and the phase, it is possible to judge absolutely how well another set of trial phases converges to the correct values. In the test calculations, amplitudes from various $T = 7$ capsid models were combined with phases from models with different morphology; refinement of the phases always converged to the phases of the model from which the amplitudes were taken. For example, refining initial phases from an all-pentamer $T = 7$ model against the amplitudes from a 60 hexmer + 12 pentamer model led back to the phases of the model built with hexamers. Thus, our refinement procedure recovers the correct structure corresponding to the amplitudes of the data even when trial starting phases were chosen to attempt to bias the calculation to produce an incorrect result.

Phase extension

The polyoma diffraction data between 30 and 22.5 Å resolution were phased by extension from the refined 30 Å phases. This was necessary because the model phases are only reliable to ~30 Å resolution. Attempts to refine the data directly to 22.5 Å resolution using trial model phases did not converge satisfactorily.

Phase extension is possible because imposition of the envelope on the electron density generates phase information for reflections just beyond the resolution of those used to calculate the map. The characteristics of phase extension were tested using model structure factors and phases in place of the real polyoma diffraction data. Starting from 30 Å resolution, using calculated amplitudes and phases as test data, it was possible to extend and refine the phases to 22.5 Å resolution. The r.m.s. phase difference between the correct and the refined extended phases were generally less than 30°.

The resolution of the actual data refinement was extended from 30 Å to 22.5 Å over 18 cycles. Predicted phases for structure factors within one reciprocal lattice distance (1/572) Å of the previous resolution were included in alternate cycles. The final *R* factor between observed and calculated structure factor

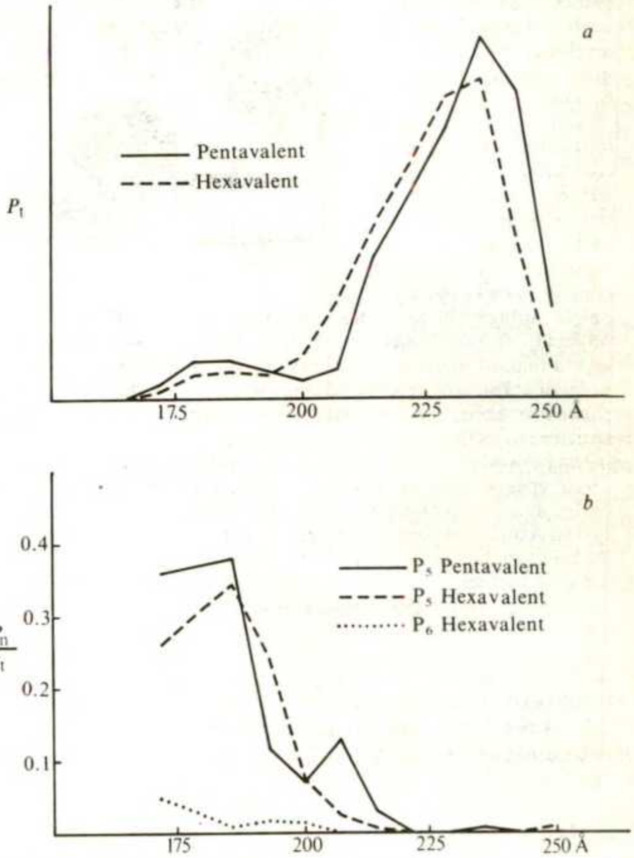

Fig. 6 Rotational power spectra of the pentavalent and hexavalent units. *a*, P_t is the sum of all cylindrical harmonics in sections of the map through the capsomeres normal to the five-fold axis and the 'best' axis of the hexavalent units, plotted as a function of the distance of the section from the centre of the particle. *b*, Relative strength of the five-fold harmonic of the pentavalent unit and the five- and six-fold harmonic of the hexavalent unit. P_t is proportional to the integrated density in each section. At small radii in the capsid a cylindrical boundary of 93 Å diameter was chosen for calculating the power spectrum of the capsomeres. These cylinders touch at a radius of 170 Å. The integrated density of the inner portions of the capsomere may be underestimated by the methods of calculation. The correspondence in the rotational power spectra distribution of the pentavalent and hexavalent units indicates a close similarity in their structures and a small difference in their radial positions. The relative strength of the order 5 harmonic for the outer portion of both the pentavalent and hexavalent capsomere is reduced because the cylindrically symmetric component, which is the dominant term in P_t, is very strong for this part of the structure. The order 5 harmonic for the hexavalent capsomere is always much stronger than that of order 6 (or any other non-zero harmonic).

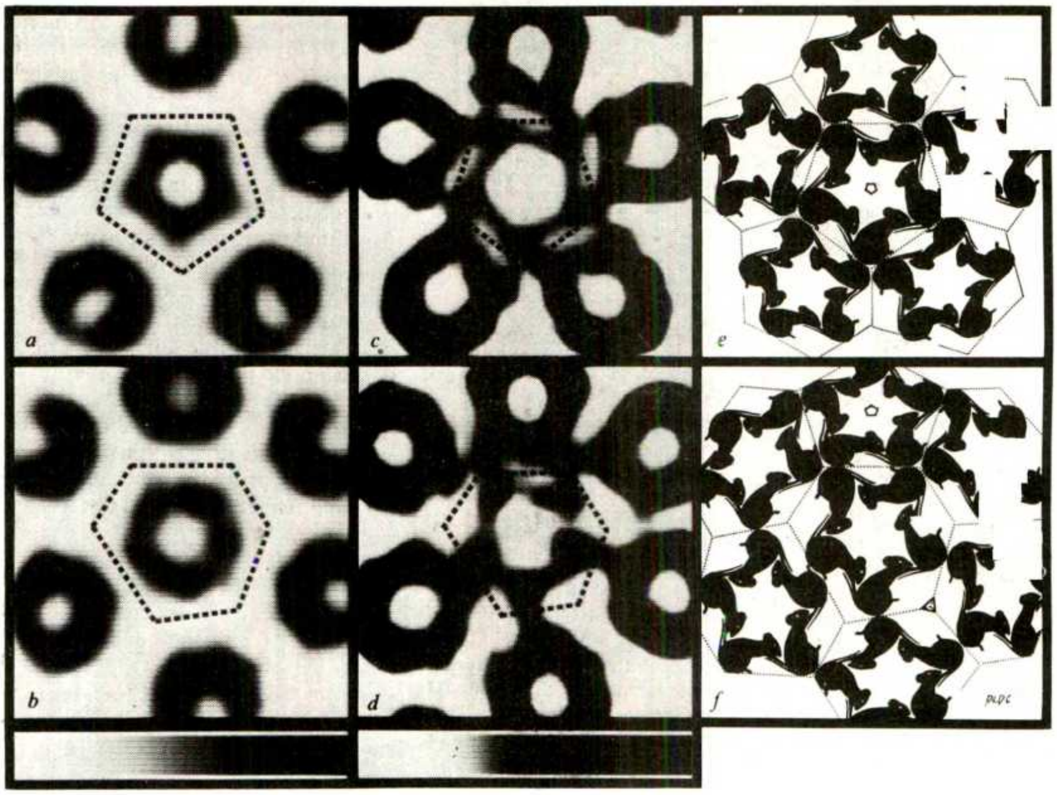

Fig. 7 Sections of the electron density map showing substructure of the capsomeres (*a–d*) and drawings on a polyhedral surface (*e*, *f*) illustrating an inferred packing relation of structure units. Upper row: views down five-fold axis and lower row: views down axis of hexavalent capsomere. Width of sections displayed 215 Å. Orientation as in Fig. 5. Grey scales at the bottom show the relation between darkness in the images and map density that increases uniformly from left to right of the scales. *a*, *b*, Maps of section planes 215 Å above centre of capsid. At this level and above there is little detectable contact between neighbouring capsomeres. *c*, *d*, Maps (displayed with enhanced contrast) of section planes 195 Å above centre. At this level and below five basal parts of the capsomeres splay out and contact basal parts of neighbouring capsomeres. Section planes are perpendicular to the axis of the central capsomere and slice through the neighbouring capsomeres obliquely. In the obliquely sectioned parts the substructure is obscured. Intersections of adjacent planes equidistant from the centre of the capsid that are normal to the axes of the pentavalent and hexavalent capsomeres define 12 equal regular pentagons and 60 equal irregular hexagons. The polygons delineating the domain of the central capsomeres are marked by dotted lines on the density maps. The drawings *e* and *f* (constructed on the polyhedral surface made up of the pentagonal and hexagonal facets) illustrate that bonding specificity among identical structure units (represented by graphically cloned mice) cannot be conserved in all the contacts between capsomeres. Arranging structure units in the hexavalent pentamer (centre of *f*) with quasi-five-fold symmetry resembling the pentagonally symmetric pentamer (centre of *e*) leads to three types of contacts between structure units of neighbouring pentamers: (1) the two structure units at the top of the central pentamer in *f* each contact two neighbours (one from the pentavalent and one from another hexavalent pentamer) related by a quasi-three-fold axis; (2) the two structure units below and right of centre in *f* make quasi-two-fold contacts with neighbours related by an icosahedral three-fold axis; (3) the one structure unit left of centre in *f* makes an intimate dimer contact with a unit equivalently related by an icosahedral two-fold axis. Thus, the six structure units in the icosahedral asymmetric unit can be put into three categories according to their bonding relations: three in the quasi-trimer, two in the quasi-dimer and one in half the strict dimer.

amplitudes was 14.2%. Figure 3*d* shows a projection down a two-fold axis of half a virus particle excised from the refined map at 22.5 Å resolution and an analysis of the *R* factor as a function of resolution and intensity at 22.5 Å resolution is shown in Fig. 4*c*, *d*.

Electron density map

Figure 5, comparing views of half a virus particle down the icosahedral five-fold axis with that down the axis of a hexavalent morphological unit, reveals a striking similarity between the penta- and hexavalent morphological units. Indeed, the hexavalent capsomere shows a distinctive five-fold character, not six-fold as would be expected from a $T=7$ icosahedral surface lattice consisting of $60T$ quasi-equivalent structure units (Fig. 1).

Power spectra of the cylindrical harmonics in sections through the penta- and hexavalent units are shown in Fig. 6. This harmonic analysis demonstrates the structural similarity between the two types of capsomeres as a function of their radial coordinates, in particular, the dominant five-fold substructure of the hexavalent unit. Icosahedral symmetry requires the 12 identical pentavalent units to have five-fold symmetry and the 60 hexavalent units to be identical; but there are no constraints on the size, shape or symmetry of the hexavalent unit. The similarity of the pentavalent and hexavalent capsomeres seen in the electron density map cannot be an artefact of the imposition of the non-crystallographic symmetry in the phase refinement. Thus, our results indicate that all 72 capsomeres are pentameres of identical or very similar subunits.

The electron density map may be divided into two regions: the protruding pentagonal caps and the basal parts connecting capsomeres. The contacts between capsomeres extend inward from ~210 Å radius of the capsid. The protruding caps are ~85 Å in diameter and extend out ~40 Å. The central hole in the capsomere has a diameter of 40 Å at a radius of 210 Å and tapers shut 15 Å from the surface, leaving a dimple on the top of the cap. The basal parts of the capsomeres extend in ~40 Å.

The similarity of the pentavalent and hexavalent morphological units seen in the electron density map, together with the chemical evidence for one kind of protein subunit, indicates that the capsid is built of 360 VP1 molecules. The radial extent of the capsid measured from the electron density map implies a protein subunit ~80 Å long. The dimensions of the wall of the pentagonal cap indicate a subunit diameter in the range 30–40 Å. An ellipsoidal subunit with these dimensions has a volume compatible with that expected for a 42,000-MW protein.

Molecular weight

All the available MW measurements are consistent with a capsid built of 360 VP1 subunits and inconsistent with a 420-subunit structure. The MW of the empty capsid, determined by sedimentation equilibrium[10], is $15 \pm 1 \times 10^6$, which agrees with the total weight of VP1 in the intact virion estimated from its MW and composition. Furthermore, the MW of 221,000 measured for isolated capsomeres[19] corresponds to a 15.9×10^6-MW capsid built of 72 identical capsomeres, in accord with the direct measurement. The calculated MW of VP1 for a $15 \pm 1 \times 10^6$-MW capsid consisting of 420 subunits would be 35,700 ± 7%, or 41,700 ± 7% for 360 copies. The calculated MW of VP1 from the DNA sequence is 42,834 (ref. 20) and 42,458 (ref. 21) for two strains of polyoma virus. These sequence values are upper limits because the protein in the capsid may be smaller due to possible post-transcriptional or post-translational processing. Estimates for the MW of VP1 from SDS-gel electrophoresis range from 42,000 to 50,000 but are not very reliable because of dependence on gel concentration[10]. Measurement by gel exclusion chromatography of VP1 dissociated with guanidine hydrochloride chloride gives a MW of 41,400 (ref. 10). Although there is no definitive MW measurement for the VP1 subunit in the capsid, all measured values are greater than or close to that expected for 360 subunits, and the smallest measured values are at least 15% larger than expected for 420 subunits.

Protein–subunit interactions

The electron density map provides information about subunit interactions even though the protein subunits themselves are not sharply resolved. Figure 7*a* and *b* are sections through the hexavalent and pentavalent capsomeres above the level at which they make contact with each other. It is evident that the projecting portions of the two kinds of capsomeres have very similar pentagonal substructure, indicating that the bonding specificity of the projecting parts of the structure units is conserved. This is analogous to the situation in the tomato bushy stunt virus structure[5] where bonding specificity is conserved within the two types of protruding dimer domains.

Where the polyoma capsomeres contact each other there are significant differences in the bonding as the five subunits of the hexavalent pentamer cannot interact equivalently with subunits of the six neighbouring pentamers. This is seen in Fig. 7*c* and *d*, which are sections at the level of contact between capsomeres. At this resolution, subunit boundaries cannot be distinguished; however, it is possible to suggest the types of interaction which would account for the observed density.

Our results show there are six structure units in the icosahedral asymmetric unit, five from the hexavalent and one from the pentavalent pentamer. Each of these subunits has a symmetrically distinct environment in the capsid. However, these six units can be put into three different classes according to their bonding relations inferred from the electron density map. These relations of the six structure units in the icosahedral asymmetric unit are schematically illustrated in Fig. 7*e* and *f*: three units are connected in one quasi-trimer, two in one quasi-dimer and one in half a strict dimer. The use of the three types of bonds can account for the assembly of the 72 pentamers in the capsid; but we do not know how the bonding specificity of the structure units is switched to control the assembly process.

Conclusion

The electron density map shows a hexavalent capsomere that closely resembles the regular pentameric capsomere in size, shape and substructure. Because the hexavalent capsomere was expected to be a hexamer, the reliability of the refinement method used to solve the structure has been critically examined. In contrast to the isomorphous replacement method in which the phase determination is constrained by measurement of heavy atom positions, and the Fourier refinement method at atomic resolution which is constrained by detailed stereochemical information, our refinement method, starting with trial phases from models representing the coarse particle morphology, is only constrained by the icosahedral symmetry and overall dimensions of the virus capsid. Our tests of the refinement method, applied to Fourier transforms calculated from capsid models to the same resolution as the experimental data, show that the constraints of the particle symmetry and overall size do lead to correct solutions starting with trial phases from any model with approximately related capsomere morphology. We believe, therefore, that the similarity of the hexavalent and pentavalent capsomeres seen in the electron density map is an intrinsic feature of the virus capsid structure rather than some unexplained artefact of the refinement procedure. As chemical analysis indicates that the capsid is built of VP1, it seems that both the hexavalent and pentavalent capsomeres are pentameres of VP1.

The similarities between polyoma virus, SV40 and other members of the papova family suggest that these may all have capsids built of pentameric capsomeres. Polymorphic tube structures are associated with all the papovaviruses. The common occurrence of pentamer tubes is understandable if all the capsomeres are pentameric. We suspect that the hexamer tubes are also made of pentamers. Re-examination of the published electron micrographs[7,8] indicates that this may indeed be the case. We are starting image analysis of electron micrographs to try to understand how the polymorphism of these structures arises.

Quasi-equivalence was conceived to explain why icosahedral symmetry should be selected for the design of closed containers built of a large number of identical structure units with conserved bonding specificity[4]. However, as bonding specificity is not conserved in the polyoma capsid, the reason for its icosahedral symmetry is no longer obvious. Why has an icosahedral capsid design of 72 pentamers been selected for polyoma and presumably other papova viruses? How is the bonding specificity of the structure unit switched to fit into the symmetrically distinct environments? Answers to these questions may be found by solving the capsid structure at higher resolution and by studying the structure of assembly intermediates.

Cellular genes analogous to retroviral *onc* genes are transcribed in human tumour cells

Polyadenylated RNAs of certain human tumour cell lines are shown to contain transcripts related to the cell-derived transforming onc *genes of molecularly cloned primate, murine or avian transforming retrovirus genomes. Thus, analogues of retroviral transforming genes are both present and frequently expressed in human neoplastic cells.*

THE study of RNA tumour viruses, designated transforming retroviruses, has provided a potentially important approach to elucidating mechanisms involved in human malignancy. These agents generally cause sarcomas and haematopoietic malignancies, but in some cases also induce carcinomas (for reviews see refs 1–4). There is convincing evidence that these viruses have arisen by recombination of replication-competent type C RNA viruses with evolutionarily well conserved cellular genes. Moreover, these latter sequences, termed *onc* genes, have been found to be required for the induction and/or maintenance of viral transformation[5–11]. Certain independent sarcoma virus isolates of the same[12–15] and even of different species[16,17] have been found to contain the same or closely related *onc* genes. These findings suggest that only a limited set of distinct cellular genes with transforming potential exists.

Molecular cloning techniques have facilitated the isolation and amplification of transforming retrovirus genomes and their cell-derived *onc* genes for detailed biochemical analysis. To investigate the possible role of *onc*-related genes in human neoplasia, we have analysed whether cellular DNA analogues of these genes are present and actively transcribed in human cancer cells.

Transforming retroviral *onc* genes as probes for detecting related transcripts in human cells

Our study required that the transforming retroviruses should meet certain criteria: (1) They should be capable of inducing a wide range of malignancies. (2) The genes used should be available as well defined genetic segments of molecularly cloned viruses. (3) Such gene segments should possess sufficient homology with human DNA to detect related information at low copy number with reasonably high signal intensity. Molecularly cloned transforming retroviruses meeting these criteria included simian sarcoma virus (SSV)[18–20], BALB murine sarcoma virus (MSV)[21], Abelson murine leukaemia virus (MuLV)[22] and MC-29 virus[23]. SSV and BALB MSV induce sarcomas in susceptible hosts[24,25], whereas Abelson MuLV causes lymphoid tumours[26]. *In vitro* and *in vivo* studies have indicated that other cell types can be targets for transformation by both Abelson MuLV and BALB MSV (refs 27, 28 and J. Hoelzer Pierce and S.A.A., unpublished observations). MC-29 has the widest known range of target cells and has been reported to induce sarcomas, haematopoietic tumours and carcinomas[2].

Infectious DNA clones of each virus were obtained by recombinant DNA techniques and their cell-derived *onc* genes defined by restriction endonuclease and heteroduplex mapping techniques[18–23]. Figure 1 shows the physical maps of the molecular clones and indicates the region of each viral genome used to prepare DNA probes. According to recent convention, the cell-derived *onc* sequences of SSV are designated *sis*, while those of Abelson MuLV, BALB MSV and MC-29 are termed *abl*, *bas* and *myc*, respectively[29].

Nick-translated DNA probes of each viral *onc* gene were first analysed for their ability to detect homologous sequences in human DNA. Normal human cellular DNA was cleaved with *Eco*RI, a restriction enzyme that did not cut within any of the viral *onc* genes (Fig. 1). The DNA was then subjected to agarose gel electrophoresis and Southern Blotting analysis[30]. As shown in Fig. 2, each viral *onc* DNA probe detected one or at most a few DNA fragments. The signal intensity was highest with the SSV *sis* DNA probe, probably reflecting its greater homology with human DNA than that of the other viral *onc* genes analysed. The DNA fragments hybridized by each viral *onc* gene had different molecular weights, indicating that each detected a different homologue within human DNA. Lack of relatedness among the viral *onc* genes was confirmed by experiments in which each nick-translated fragment was hybridized to Southern blots containing the four unlabelled viral *onc* DNAs. Even in relaxed hybridization conditions[31], there was no detectable relatedness among the *onc* genes of SSV, BALB MSV, Abelson MuLV or MC-29 (data not shown).

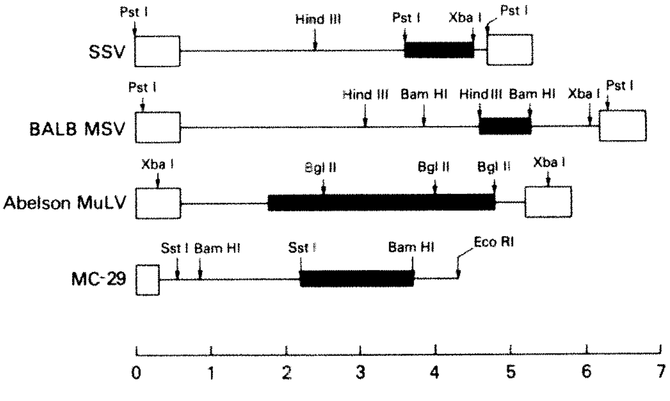

Fig. 1 Restriction maps of transforming retroviral genomes used to detect *onc*-related sequences in human cells. The *onc* genes of each retrovirus are indicated by the solid boxes. The white boxes represent the long terminal direct repeats (LTRs). Pertinent restriction sites are indicated. The integrated biologically active form of each viral genome was cloned in a λ phage vector[18–23]. Host cellular flanking sequences are not shown. DNA probes were derived from subgenomic fragments of each viral *onc* gene as follows: SSV, *Pst*I–*Xba*I fragment; BALB MSV, *Hind*III–*Bam*HI fragment; Abelson MuLV, 5′ *Bgl*II–*Bgl*II fragment; MC-29, *Sst*I–*Bam*HI fragment. With the exception of SSV, each subgenomic DNA fragment was cloned in pBR322.

0028–0836/82/020116—04$01.00

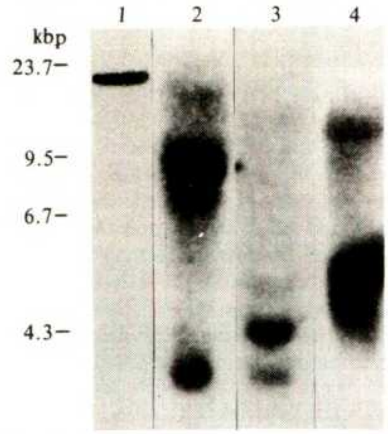

Fig. 2 Detection of human DNA sequences related to transforming retroviral *onc* genes. High-molecular weight human placental DNA was digested with *Eco*RI and electrophoresed on 0.8% agarose gels. Southern blots were prepared and incubated for 24 h with 2×10^6 c.p.m. ml^{-1} nick-translated (2×10^8 c.p.m. per μg) viral *onc* probes prepared from cloned DNAs of SSV (lane 1), BALB MSV (lane 2), Abelson MuLV (lane 3) and MC-29 (lane 4). Hybridization with the SSV *sis* probe was performed at 50 °C in 50% formamide and 5×SSC followed by washing at 50 °C with 6×SSC as described previously[17]. The other probes were hybridized at 65 °C in 6×SSC and washed at 45 °C in 0.1×SSC–0.1% SDS according to Hieter *et al.*[49]. The blot in lane 1 was exposed for 16 h, and those in lanes 2–4 were exposed for 48 h using Kodak XAR-5 film and Dupont Cronex Lightning Plus screens. *Hind*III-generated fragments of bacteriophage λ DNA were used as molecular weight standards: kbp, kilobase pairs.

In our search for transcripts related to viral *onc* genes in human tumours, we selected tumour cell lines representing a diverse spectrum of malignancies, including carcinomas, sarcomas, melanomas and glioblastomas. The establishment and biological characterization of some of these cell lines have been reported previously (Table 1). Each cell line was malignant in athymic nude mice and reproduced the histopathology of the original tumour (refs 32, 33 and S.A.A. and N. W. Ellmore, unpublished observations). These established lines enabled us to conduct a systematic analysis of viral *onc* gene expression in human malignancies.

The approach used to detect *onc*-related transcripts in human tumour cells involved isolation of poly(A)-containing RNAs and analysis by agarose gel electrophoresis and Northern blotting techniques[34–36]. Selection of poly(A)-containing RNAs provided the most sensitive method of detecting transcripts with properties of most known mRNAs, the sensitivity of detection of viral RNA in a typical retrovirus-transformed nonproducer cell being enhanced 30–40 fold by this procedure. This enhancement was consistent with the enrichment expected from the known fraction of poly(A)-containing RNA in total cellular RNA[37] and the percentage of poly(A)-containing RNA recovered by oligo(dT) selection[34]. Human cells were routinely tested for the presence of viral *onc*-related transcripts both as total and poly(A)-selected RNAs. In no case did we detect transcripts in total RNA that were not present in the poly(A) fraction. All cell lines were analysed for transcripts related to each viral *onc* gene. In some experiments, blots were sequentially hybridized with different *onc* probes as an internal control of the level of expression of the different *onc*-related transcripts.

SSV *sis* gene expression specific for certain human tumour cells

Nick-translated SSV *sis* DNA detected a single 4.2-kilobase (kb) transcript in 8 of 23 human tumour cell lines analysed, including 5 of 6 sarcoma cell lines and 3 of 5 glioblastoma lines. As shown in Fig. 3, the signal intensity of this transcript varied, the highest level being detected in a human glioblastoma line, A172 (Fig. 3, lane 1). The transcript was present at somewhat lower level in each of the positive sarcoma cell lines, as indicated for representative osteosarcoma and fibrosarcoma lines (Fig. 3, lanes 2 and 3, respectively). A second RNA species of lower molecular weight and much lower signal intensity was occasionally detected in some of the cell lines showing the 4.2-kb transcript. SSV *sis* gene expression was specific for these tumours as RNA isolated from normal human embryonic fibroblasts did not detectably hybridize (Fig. 3, lane 4). Furthermore, the SSV *sis*-related transcript was not observed in poly(A)-selected RNAs of any carcinoma, melanoma or other tumour cell line analysed. Note that SSV nonproducer cell RNA (Fig. 3, lane 5) exhibited genomic and one subgenomic RNA species containing *sis* sequences, neither of which corresponded in size to that of the 4.2-kb *sis*-related transcript in human sarcomas or glioblastoma cells.

A single MC-29 *myc*-related transcript in human tumour cells of different origins

The MC-29 *myc* probe, like SSV *sis*, detected a single transcript in human tumour cells. As shown in Fig. 4, this 2.7-kb transcript was observed in all cell lines examined, including normal human fibroblasts. Although the Northern blotting technique is not highly quantitative, there seemed to be a striking increase in the levels of *myc*-related RNA in some tumour cell lines analysed. In repeated experiments with the same RNAs or with RNAs independently prepared from the same cell lines, we reproducibly observed a 5–10-fold higher signal intensity of this transcript in lines derived from a sarcoma (A1383) and two carcinomas (A2780 and A549) as well as in the NC37 B-lymphoid line (Fig. 5). NC37 cells were initially established from Epstein–Barr virus (EBV)-positive lymphoid cells of a normal human[38]. However, NC37 cells also possess an abnormal karyotype and are tumorigenic in nude mice (unpublished observations), indicating their malignant phenotype. Notably, there was no correlation between those cell lines demonstrating high levels of the 2.7-kb MC29 *myc*-related RNA and those containing the 4.2-kb SSV *sis*-related transcript.

Table 1 Human tumour cell lines studied

Origin	Cell line	Ref.	Origin	Cell line	Ref.	Origin	Cell line	Ref.

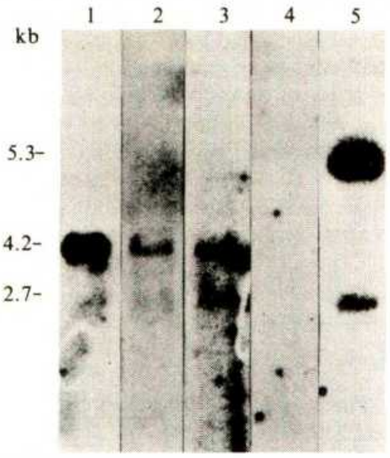

Fig. 3 SSV *sis*-related transcripts in human tumour cell lines. Total cellular RNA was isolated by a modification of the guanidine hydrochloride extraction method[50] as described elsewhere[51]. Poly(A)-containing RNA was selected by one cycle of chromatography on oligo(dT)-cellulose columns[34]. Poly(A)-containing RNAs (5 μg per lane) were denatured in 13 mM methyl mercury hydroxide and size fractionated on 1% agarose gels containing 5 mM methyl mercury[35] and transferred to nitrocellulose filters as described previously[36]. RNAs containing SSV *sis*-related sequences were identified by hybridization with 2.5×10^6 c.p.m. μl^{-1} nick-translated (2×10^8 c.p.m. per μg) *Pst*I–*Xba*I DNA fragment of molecularly cloned integrated SSV DNA[18–20]. Hybridization with the SSV *sis* probe was performed in 20% formamide, 5×SSC at 37 °C for 36–48 h, followed by washing at 42 °C in 0.1×SSC, 0.1% SDS as described previously[36,49]. SSV *sis*-related transcripts were visualized by exposing the blots to X-ray films for 5–7 days with intensifying screens. Poly(A)-selected RNAs included those from: A172 glioblastoma cells (lane 1); HOS and 8387 human sarcoma cells (lanes 2 and 3); M413 normal human fibroblasts (lane 4); SSV nonproducer NRK cells (lane 5).

Multiple transcripts related to mouse *onc* genes in human tumour cells

onc gene probes of two mouse-derived transforming viruses, BALB MSV and Abelson MuLV, each detected related transcripts in all human tumour cell lines analysed. Figure 6 shows the results with representative tumour cell lines. The pattern of BALB MSV *bas*-related transcripts was complex (Fig. 6*a*), showing three distinct bands of 7.0, 5.9 and 1.8 kb, in many tumours. Some tumour cell lines seemed to contain a much lower level of the 1.8-kb transcript whereas in other cells, including normal human fibroblasts, this RNA species was not detected.

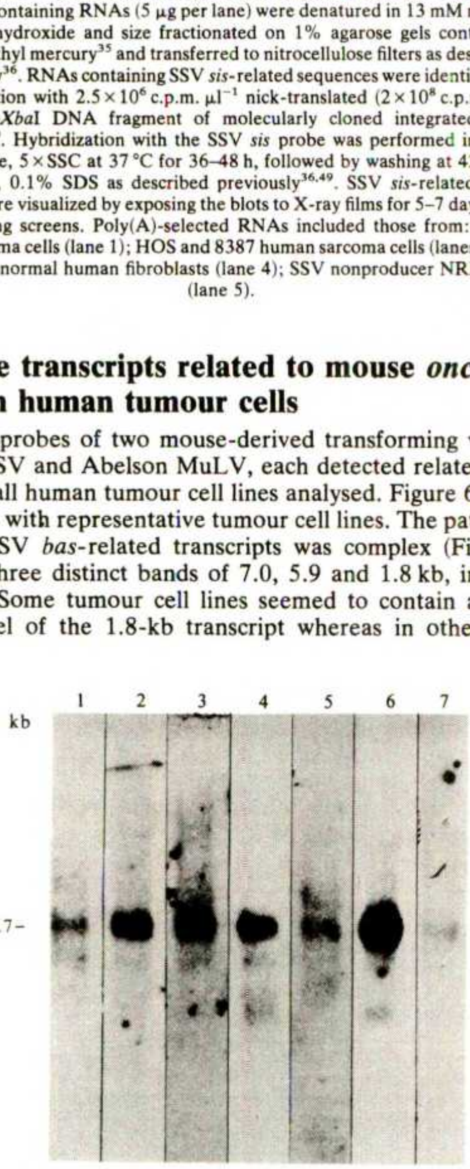

Fig. 4 MC-29 *myc*-related transcripts in human tumour cells. Poly(A)-selected RNAs were prepared and analysed as described in Fig. 3 legend. MC-29 *myc*-related transcripts were identified by hybridization with 2.5×10^6 c.p.m. ml^{-1} nick-translated *Sst*I–*Bam*HI DNA fragment of molecularly cloned integrated MC-29 DNA[23]. Poly(A)-selected RNAs include those from: A2394 and A2095 sarcoma cell lines (lanes 1 and 2); A2780 and A549 carcinoma cell lines (lanes 3 and 4); A375 melanoma cell line (lane 5); NC37 B-lymphoid cell line (lane 6); M413 normal human fibroblasts (lane 7).

An even more complex pattern of transcripts was observed with the Abelson MuLV *abl* probe. At least five RNA species were detected in most of the tumour cell lines analysed (Fig. 6*b*), while normal fibroblasts demonstrated only the two largest *abl*-related transcripts. The widespread presence in tumours and even normal fibroblasts of multiple transcripts related to the *onc* genes of BALB MSV and Abelson MuLV suggests that expression of related human genes may be associated with an important cellular function(s). Whether the multiple RNAs observed with these probes reflect RNA processing or transcription of more than one member of a family of related *onc* genes remains to be determined.

Implications of retroviral *onc* gene expression in human cells

The present report demonstrates that sequences related to the *onc* genes of different transforming retroviruses are not only present in human DNA but can also be actively transcribed. Retroviral *onc* genes have been transduced by type C RNA viruses from the genomes of species as diverse as primates, mice and chickens (for reviews see refs 1–4), and their presence in the DNAs of diverse vertebrate species, including man, indicates that such genes are highly conserved. Our findings that these genes are actively transcribed in human normal and/or neoplastic cells as polyadenylated RNA species provides additional evidence for the functional nature of these well conserved genetic elements.

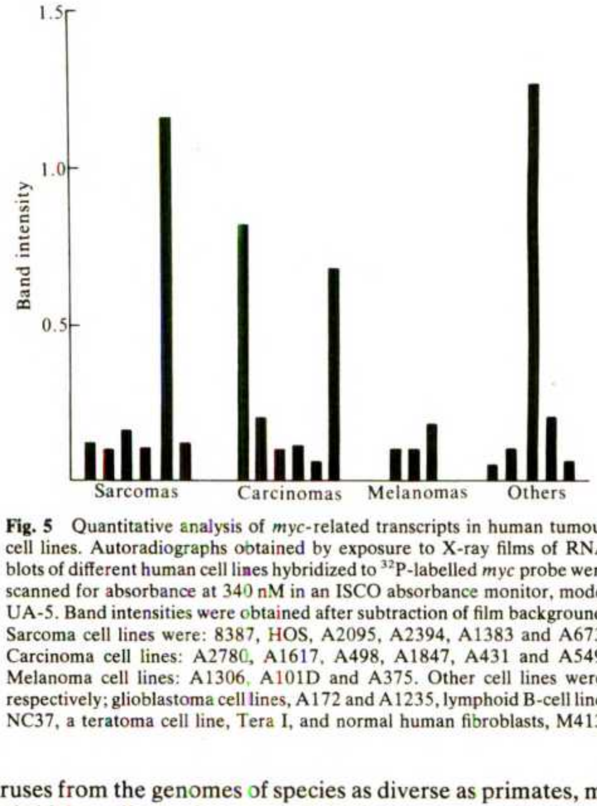

Fig. 5 Quantitative analysis of *myc*-related transcripts in human tumour cell lines. Autoradiographs obtained by exposure to X-ray films of RNA blots of different human cell lines hybridized to ^{32}P-labelled *myc* probe were scanned for absorbance at 340 nM in an ISCO absorbance monitor, model UA-5. Band intensities were obtained after subtraction of film background. Sarcoma cell lines were: 8387, HOS, A2095, A2394, A1383 and A673. Carcinoma cell lines: A2780, A1617, A498, A1847, A431 and A549. Melanoma cell lines: A1306, A101D and A375. Other cell lines were, respectively; glioblastoma cell lines, A172 and A1235, lymphoid B-cell line, NC37, a teratoma cell line, Tera I, and normal human fibroblasts, M413.

It is clearly important to determine whether viral *onc* genes are critical to the transformation process in humans. It has recently been shown that genetic manipulation of a cloned normal mouse cell DNA analogue of one transforming retroviral *onc* gene so as to cause it to be transcriptionally activated, confers on it the ability to transform mouse cells[9,39]. Moreover, other studies have indicated that leukaemia viruses may induce tumours by a mechanism involving 'downstream' promotion and transcriptional activation of cellular gene(s)[40–42]. The markedly elevated levels of single transcripts related to either SSV or MC29 *onc* genes in certain human tumour cells are consistent with the transcriptional derepression of these genes. Thus, if

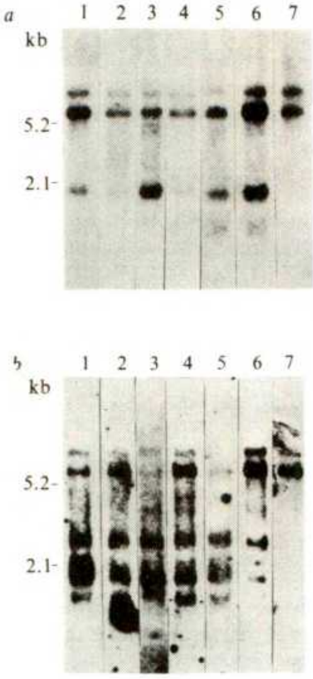

Fig. 6 BALB MSV and Abelson MuLV *onc* gene-related transcripts in human tumour cells. Poly(A)-selected RNAs were prepared and analysed as described in Fig. 3 legend. *a*, BALB MSV *bas*-related transcripts were identified by hybridization with 2.5×10^6 c.p.m. ml^{-1} nick-translated *Hin*dIII–*Bam*HI DNA fragment of molecularly cloned integrated BALB MSV DNA[21]. Poly(A)-selected RNAs include those from: A2095 and HOS sarcoma cell lines (lanes 1 and 2); A549 and A2780 carcinoma cell lines (lanes 3 and 4); A1306 melanoma cell line (lane 5); A1235 astrocytoma cell line (lane 6); M413 normal human fibroblasts (lane 7). *b*, Abelson MuLV *abl*-related transcripts in poly(A)-containing RNAs of cell lines as indicated in *a* were identified by hybridization with 2.5×10^6 c.p.m. ml^{-1} nick-translated 5′ *Bgl*II–*Bgl*II DNA fragment of molecularly cloned integrated Abelson MuLV DNA[22].

their functional products were analogous to those of the SSV and MC29 transforming genes, the specific transcriptional activation of these *onc*-related genes in certain human tumours may be sufficient to explain the transformed state of the cells.

The present studies used human tumour cell lines rather than primary tumours because of technical difficulties in obtaining sufficient amounts of intact RNAs from the latter. In each case, the tumour cell lines used reproduced the histopathology of the primary tumour in nude mice, indicating that each preserved the transformed phenotype of the original tumour. Our findings of marked differences in the levels of expression of SSV *sis* and MC-29 *myc* transcripts among various cell lines further argue that the increased expression of these genes in only some tumour lines is not attributable to tissue culture adaptation. We have recently examined the expression of retroviral *onc*-related RNAs in a variety of human primary tumours and tumour cell lines of haematopoietic origin[52] and found the levels of expression of the different *onc* gene-related transcripts in both fresh and cultured cells to be comparable, with no evidence of alteration associated with tissue culture.

Our demonstration of SSV *sis*-related transcripts in human fibrosarcoma cell lines but not in their normal fibroblast counterparts argues that the expression of this *onc* gene is probably associated with the transformed state of the cells. Moreover, the differences in levels of expression of *sis* or *myc* genes among individual carcinoma or glioblastoma cell lines suggest that the expression of these genes cannot be correlated with a particular tissue type. The more complicated patterns of transcripts related to BALB MSV and Abelson MuLV *onc* genes in human normal and neoplastic cells raise additional questions concerning the mode of processing of such transcripts, and their source from one or more related genes. Nonetheless, the almost universal presence of these transcripts in human cells argues strongly that these viral *onc*-related genes possess some important function(s). Whether they are directly related to the malignant state or to specific stages of cellular differentiation remains to be determined.

Understanding of the mechanisms involved in human neoplastic transformation is still at a very early stage. Recently, Krontiris and Cooper[43] and Weinberg and co-workers[44] provided evidence that cellular transformation can be a consequence of a single dominant genetic change, as transfection with DNA of certain tumours transmitted the transformed phenotype. In other cases, the transformed phenotype has not been transferable[43,44] or has seemed to be recessive in somatic cell hybrids with normal cells[45], arguing that the genetic changes associated with transformation may be *trans*-acting or multiple.

One approach to investigating whether the high levels of expression of human cellular analogues of certain viral *onc* genes are aetiologically linked to the development of the neoplastic state extends from the model for transformation associated with dominant genes. We are now analysing DNAs from some of our tumour cell lines for transforming activity in transfection assays. Should these DNAs possess the ability to transform cells, it will be possible to probe such transformants for expression of transcripts of the type specifically elevated in the original tumour cell lines. By such an approach, it may be possible to establish directly whether the high levels of expression of these genes in some human tumours is causally related to the neoplastic state.

DNA sequences necessary for transcription of the rabbit β-globin gene *in vivo*

G. C. Grosveld, E. de Boer, C. K. Shewmaker* & R. A. Flavell

Laboratory of Gene Structure and Expression, National Institute for Medical Research, Mill Hill, London NW7 1AA, UK

The DNA sequences required for the expression of the rabbit β-globin gene in vivo *have been examined. A variety of mutant rabbit β-globin gene templates were linked to a simian virus 40–plasmid recombinant and introduced into HeLa cells; in these conditions the rabbit β-globin gene is expressed from its own promoter. Comparison of the level of β-globin transcripts in a variety of deletion mutants shows that for efficient transcription, both the ATA or Goldberg–Hogness box, and a region between 100 and 58 base pairs in front of the site at which transcription is initiated, are required. Deletion of either of these regions results in a decrease in the level of β-globin transcripts by an order of magnitude; deletion of the ATA box causes an additional loss in the specificity of the site of initiation of RNA synthesis. The DNA sequences downstream from the ATA box, including the natural β-globin mRNA cap site, are dispensable for transcription* in vivo.

ALTHOUGH we have a good understanding of the DNA sequence elements which constitute prokaryotic promoters, their eukaryotic counterparts are poorly defined. Comparison of the DNA sequences in the 5′ extragenic regions of a large number of genes has revealed two conserved sequence elements with a location consistent with a promoter-like role. The first of these is an A+T-rich region with the canonical sequence 5′ TATA$^{T}_{A}$A$^{T}_{A}$ 3′ (the Goldberg–Hogness or ATA box)[1,2] which is located about 30 base pairs (bp) upstream from the site of initiation of RNA synthesis. The second is the CCAAT box[3,4] located about 80 nucleotides upstream from the cap site. Considerable evidence now indicates that RNA synthesis initiates at the cap site (see, for example, refs 5, 6).

In vitro transcription systems have recently been developed that synthesize specific capped transcripts from a variety of viral and cellular gene templates[7,8]—again *in vitro* the site of initiation is the cap site. Using these *in vitro* systems, several groups have shown that the ATA box is required for specific transcription of the adenovirus late[9,10] conalbumin[11] and β-globin[12] genes *in vitro*. Deletion of the CCAAT box has little or no effect on the *in vitro* transcription of the these genes[9–12]. The comparative simplicity of the *in vitro* results is not, however, found *in vivo*. In the case of the simian virus 40 (SV40) early region, deletion of the ATA box does not prevent expression of the early mRNAs, and removal of the DNA sequences containing the 72-bp repeat localized at ∼150 bp (−116 to −188; and −189 to −261) upstream from the site of initiation of RNA synthesis abolishes early gene transcription[13]. A similar picture is seen for polyoma (R. I. Kamen, personal communication). Likewise, a segment of ∼50 nucleotides containing the ATA box is not required for the expression of the sea urchin histone H2A gene when it is injected into *Xenopus* oocytes[14,15]. However, this deletion does alter the specificity of the site of initiation and causes the appearance of at least three transcripts with discrete 5′ ends. This alteration of the specificity of initiation also occurs when the ATA box of the early region of SV40 is deleted[13]. There is also evidence for the role of upstream DNA sequences in the transcription of the histone H$_2$A gene *in vivo*: deletion of a DNA segment containing the sequences from −184 to −524 strongly reduces the level of synthesis from the histone H2A promoter[15].

It is unclear at present to what extent the recent results obtained in the two systems represent the general sequence organization of eukaryotic promoters and to what extent the results are gene specific, or specific to the test system used. There is no obvious sequence homology between the upstream DNA sequences necessary for transcription in SV40 and in the sea urchin H2A gene that would point to a common promoter element. The SV40 72-bp repeat may represent more than a simple promoter element in the sense that this term is used for prokaryotic promoters (see below).

We have recently examined the *in vitro* transcription of a wide range of deletion mutants of the rabbit β-globin gene in HeLa cell extracts[12]. It is important to determine the effects of deletion of these DNA sequences on the expression of this gene *in vivo* and in the same cell type—particulary given the obvious differences recently seen between *in vivo* and *in vitro* transcription in the SV40 and polyma systems. In addition, we would like to know whether there is any evidence for upstream DNA sequences analogous to those of the SV40 and histone genes in the rabbit β-globin gene system.

To date, two approaches have been used to analyse the transcription of globin genes *in vivo* in animal cells. Mantei *et al.*[16] linked the rabbit β-globin gene to the herpes simplex virus (HSV) thymidine kinase (TK) gene and transformed mouse TK$^-$ cells to the TK$^+$ phenotype. Those cells containing the β-globin gene expressed this at a low, but easily detectable, level. Although this method has the advantage that only a few copies of the β-globin gene are present per cell, the comparison of different transformant cell lines is complex, because the exogenous DNA has become integrated and in each case the site of integration appears to differ. Hamer *et al.* have analysed the expression of the mouse α-globin gene, as an SV40–mouse α-globin recombinant after its introduction into monkey cells permissive for SV40 replication[17]. In these conditions the mouse α-globin gene is expressed at a high level from its own promoter. It was recently shown[20] that the rabbit β-globin gene inserted (as a 4.8-kilobase (kb) *Kpn*I fragment; see Fig. 1) in the *Kpn*I site of an SV40–pBR322 recombinant is expressed from its own promoter in HeLa cells which are only semi-permissive for SV40 replication. In the present work, we use this SV40–HeLa system to analyse the transcription *in vivo* of a number of deletion mutants of the rabbit β-globin gene.

To assay for the expression of the rabbit β-globin gene, we used S_1 mapping procedures[18], in most cases using as probe a 221-bp *Bst*NI fragment ^{32}P-labelled at its 5′ end using polynucleotide kinase. When hybridized to this probe, rabbit globin mRNA protects a 139-nucleotide fragment from S_1 nuclease digestion (Fig. 1). This variant of the S_1 mapping protocol permits the determination of the 5′ end of the respective transcripts to within 1–2 nucleotides[19].

We have analysed the expression of the rabbit β-globin gene at two different sites of insertion in the SV40–plasmid recombinant. The first site is the *Kpn*I site of the origin region of SV40 on the plasmid pSVβG*Kpn* (Fig. 1), that is, the original plasmid analysed by Banerji, Rusconi and Schaffner[20]. In this case, the rabbit β-globin gene is inserted in the promoter region of SV40.

In agreement with their original observations, we found that the rabbit β-globin gene is transcribed from its own promoter in these conditions since RNA from HeLa cells infected with this SV40–globin recombinant protects a fragment the same length as that given by normal rabbit β-globin mRNA (Fig. 1).

To investigate whether the rabbit β-globin gene must be present embedded within the SV40 moiety of the recombinant, we first constructed an SV40–pBR328 recombinant by ligating the two respective *Bam*HI–*Eco*RI double digest fragments of SV40 and pBR328 (see Fig. 2). The resultant plasmid, which is analogous to that of Schaffner except that pBR322 is replaced by pBR328, contains the entire early region of SV40, but lacks a 751-bp segment of the late region. We inserted the 2,070-bp *Bgl*II partial digest fragment, which contains the entire rabbit β-globin gene, together with 425 nucleotides of 5′-flanking DNA sequences and 355 nucleotides of the 3′-flanking regions, into the *Bam*HI site of the SV40–pBR328 recombinant. The globin gene segment is therefore interposed between the late region of SV40 and the remaining 3′ segment of the tetracycline gene of pBR328. Since this β-globin gene lacks the DNA regions to the 5′ side of position −425, we shall refer to this recombinant as ∇ 5′ to −425. The rabbit β-globin gene is expressed specifically in both of the two possible orientations (Fig. 1). Clearly then, the globin gene segment does not need to be embedded in the SV40 promoter region. We have estimated the approximate level of β-globin mRNA by standardizing our S_1 mapping procedures with purified rabbit $\alpha + \beta$ globin mRNA (see, for example, Fig. 4). From these data we calculate that ~10,000 molecules of β-globin mRNA are produced assuming that all cells are expressing the β-globin genes. As the real fraction of cells expressing the gene is likely to be significantly lower than this (usually 15–30% of the cells are positive for SV40 antigen), this value is probably an underestimate by a factor of 2–5.

From the above experiments it can be seen that the rabbit β-globin gene is expressed on an SV40 plasmid in at least two different sites with respect to both the SV40 and plasmid sequences; expression is independent of the orientation of the β-globin gene with respect to the SV40 plasmid DNA sequences. We have obtained similar results with the human β-globin gene (C.K.S., N. Moschonas and E. de B., unpublished) derived from both normal and β°-thalassaemic individuals. Although in these cases the early region of SV40 is also present, a functional early region is not required for this expression[20].

Rabbit DNA sequences necessary for expression of the rabbit β-globin gene *in vivo*

To determine which rabbit DNA segments are required for the expression of the rabbit β-globin gene in HeLa cells, we have prepared a series of deleted rabbit β-globin genes and introduced these into the SV40–plasmid recombinant. This insertion was performed as described in Fig. 2 legend, and results in the replacement of the pBR328 moiety of the SV40 recombinant with that of pAT153, another pBR322-derived bacterial plasmid. In the first case examined, the rabbit β-globin gene segment extends from −100 to approximately +1,870; the recombinant therefore contains 100 nucleotides of 5′ extragenic DNA sequences and ~280 nucleotides of 3′ extragenic DNA sequences. The plasmid segment (pAT153) is in the opposite orientation to that described above for ∇ 5′ to −425 and the rabbit DNA segment is interposed between the 3′ segments of the β-lactamase gene of pAT153 and the late region of SV40 DNA (at nucleotide 2,468)[21,22]. Following the same terminology, we shall call this recombinant ∇ 5′ to −100. We have examined the transcripts found in HeLa cells for only one orientation of the β-globin gene (where the 5′ end of the β-globin gene adjoins the plasmid sequences), but here again, a high level of rabbit β-globin mRNA is produced with its 5′ end

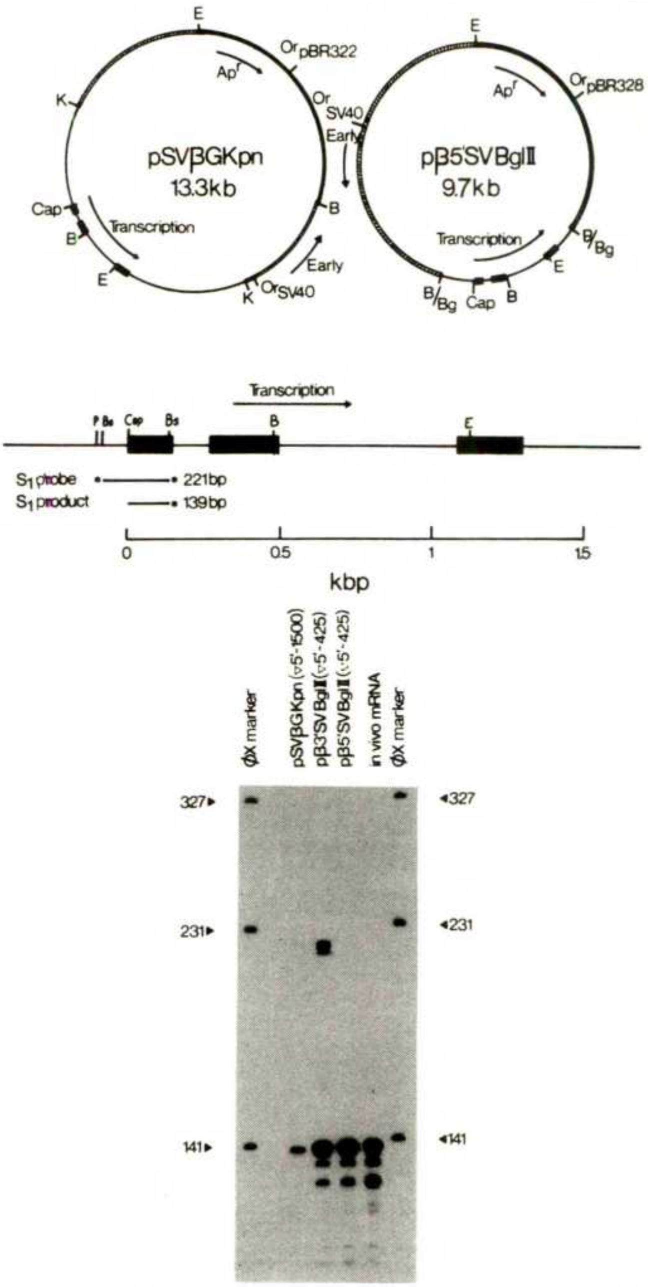

Fig. 1 Transient expression of the rabbit β-globin gene linked to SV40 sequences in HeLa cells. 15 μg DNA from either pSVβG*Kpn*, pβ5′SV*Bgl*II or pB3′SV*Bgl*II (which has the same structure but the β-globin gene segment is in the opposite orientation with respect to the SV40 sequences) were mixed with 25 μg of salmon sperm DNA and used to transform a half-confluent 100-mm dish of HeLa cells using the calcium phosphate method[27]. Three dishes were used for each DNA sample. After 10 h the medium (H21, 10% newborn calf serum) was changed, the cells grown for another 24 h, collected and the RNA isolated by the LiCl–urea method[28]. The upper part of the figure shows schematic restriction maps of pSVβG*Kpn* and pβ3′SV*Bgl*II DNA. pSVβG*Kpn* contains the 3.9-kb *Bam–Eco* fragment of pBR322, the 4.4-kb *Bam–Eco* fragment of SV40 and the 4.8-kb *Kpn*I rabbit β-globin fragment ligated into the *Kpn*I site of SV40 DNA. The construction of pβ3′SV*Bgl* and pβ5′SV*Bgl* DNA is outlined in Fig. 2—they contain the 2-kb rabbit β-globin *Bgl*II partial fragment in two orientations with respect to the SV40 sequences ligated into the *Bam*HI site of the SV40–pBR328 DNA junction. The rabbit β-globin RNAs present in the transformed HeLa cell RNA were detected by S_1 mapping[18] using end-labelled DNA probes[19]. In the centre of the figure is the 221-bp *Bst*NI 5′-labelled fragment used as probe in this experiment, containing 139 nucleotides of the 5′ end of the rabbit β-globin gene, which is protected against S_1 nuclease digestion in the DNA–RNA hybrid. The lower part of the figure shows the S_1 products of globin RNAs from HeLa cells transformed with vector DNA, pSVρG*Kpn* DNA, pβ3′SV*Bgl*II or Pβ5′SV*Bgl*II DNA analysed on a 5% polyacrylamide sequence gel[29] (SVpBR328, see Fig. 2). As a positive control the S_1 product of the *Bst*NI probe with *in vivo* rabbit β-globin mRNA is shown. The labelled marker is ΦX174 × *Hae*III. The numbers on the side are the lengths of the marker fragments in nucleotides. Hatched areas represent SV40 DNA, solid lines plasmid sequences, and thin lines and filled boxes the rabbit β-globin exons.

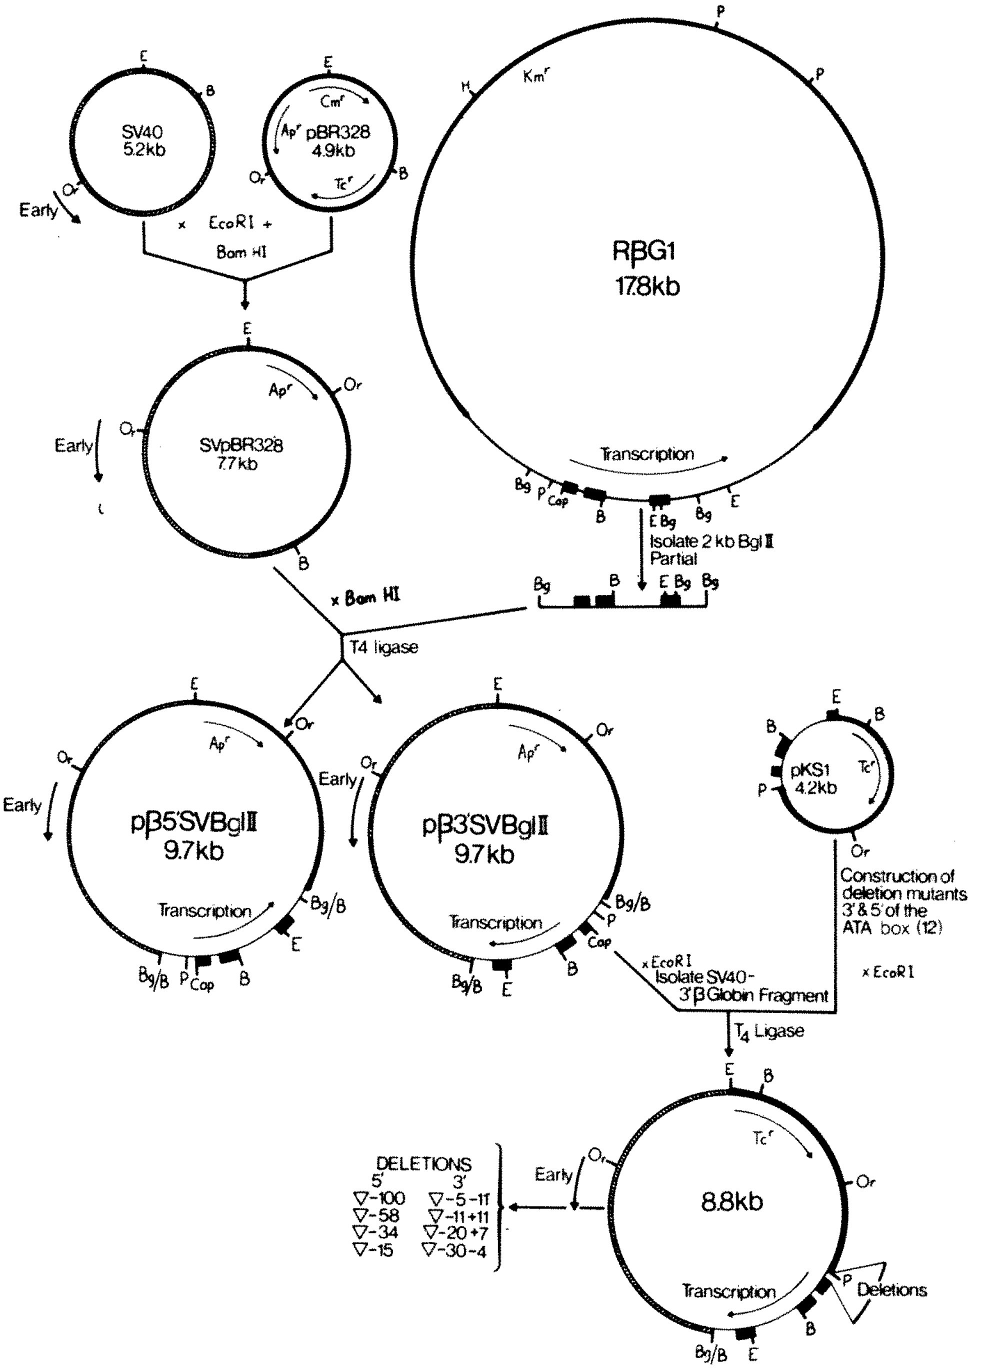

Fig. 2 Construction of SV40 derivatives of β-globin DNAs deleted in the promoter region. To prepare SVpBR328, SV40 DNA and pBR328 DNA (each 5 μg) were digested with *Eco*RI and *Bam*HI, both large *Bam–Eco* fragments were cut out from a 0.5% low melting agarose gel, purified on a DEAE 52 column[19] and ligated for 4 h at 15 °C at a DNA concentration of 20 μg ml^{-1} with T4 ligase and transfected into *Escherichie coli* HB101. From the ampicillin-resistant colonies an SV40–pBR328 recombinant was isolated. To clone the 2-kb *Bgl*II fragment (which contains the rabbit β-globin gene) into this vector, 50 μg RβG-1 DNA were partially digested with *Bgl*II and loaded on a 0.5% low melting agarose gel. The 2,070-bp β-globin *Bgl*II partial band was cut out and the DNA recovered by DEAE cellulose chromatography. This fragment was ligated into the *Bam*HI-linearized pBSV328 DNA at a final concentration of 20 μg DNA per ml. From the ampicillin-resistant colonies both orientations of the globin fragment were isolated with the globin 5′ end facing SV40 (pβ*5′SV Bgl*II) and the globin 3′ end facing SV40 (pβ3′SV*Bgl*II) respectively. pKSI DNA, a plasmid containing the *Pst*I-*Eco*RI rabbit β-globin gene fragment (containing the globin sequences from −100 to +1,120) inserted into *Pst*I-*Eco*RI of PAT153[12], was used to produce deletions in the globin promoter region[12] with end points to the 5′ side of the ATA box (−100, −58, −34, −15) and the 3′ side of the ATA box (−11 −5, −11 +11, −20 + 7, −30 + 4). To clone these DNAs into an SV40-containing vector, 25 μg 5′pβ5′SV *Bgl*II DNA was digested with *Eco*RI and the 4.8-kb SV40–globin band containing *Bam–Eco* SV40 and the 3′ end of the rabbit β-globin gene was recovered from a 0.5% low melting agarose gel. Then *Eco*RI-linearized pKSI DNA or DNA from the derivative deletion clones was ligated (20 μg ml^{-1}) into this fragment. Tetracycline-resistant colonies that hybridized to SV40 DNA were picked and screened by restriction analysis. Hatched area, SV40 DNA; solid lines, plasmid sequences; thin lines, rabbit DNA; filled boxes, the β-globin exons.

coincident with that of natural rabbit β-globin mRNA (Fig. 3.). In addition to this component, however, a number of bands are seen which identify the presence of RNAs with 5′ ends at several sites from +42 to +48. As these bands are seen when a 5′-labelled 221-nucleotide *Bst*NI minus strand probe is used, these components must be transcribed from the same DNA strand as β-globin mRNA. Together these bands amount to about twice the number of RNA molecules formed from the normal rabbit β-globin promoters. These components are also seen in the case of the ∇ 5′ to −425 mutant (that is, the *Bgl*II fragment discussed above), but the abnormal products comprise only about one-third of the total β-globin transcripts. The same abnormal RNAs have been described previously[23,24] as transcripts produced from the rabbit β-globin gene when introduced into mouse L cells and maintained as stable TK⁺ transformants. We have also synthesized cDNA on RNA from HeLa cells transfected with the rabbit β-globin gene using an *Sfa*NI–*Bst*NI fragment (from the 3′ end of the first exon) labelled at its 5′ end. This experiment reveals cDNAs corresponding to natural β-globin mRNA and a second predominant cDNA which derives from an upstream promoter, in addition to several minor shorter cDNA bands which presumably result from early termination of cDNA synthesis. As no cDNA is seen that would correspond to a RNA with a 5′ end at +42 to +48, we conclude that the 5′ ends detected by S_1 mapping do not result from transcriptional initiation events, but probably derive from upstream RNAs which splice to the A-G at position +47 and +48 of the rabbit β-globin gene. In addition, in S_1 mapping experiments we see a low level of transcripts derived from a plasmid or SV40 promoter.

We have introduced a variety of deletion mutants, derived originally from ∇ 5′ to −100, into the SV40–plasmid at the same site, and in the same orientation as the ∇ 5′ to −100 mutant. Thus, each mutant is inserted with the 5′ moiety of the rabbit β-globin gene adjacent to the 3′ regions of the β-lactamase gene. The DNA sequence of each mutant DNA has been determined around the regions spanning the deletion and Fig. 5 shows the relevant areas of sequence.

These DNAs have been introduced into HeLa cells in standard conditions and the 5′ ends of the transcripts produced

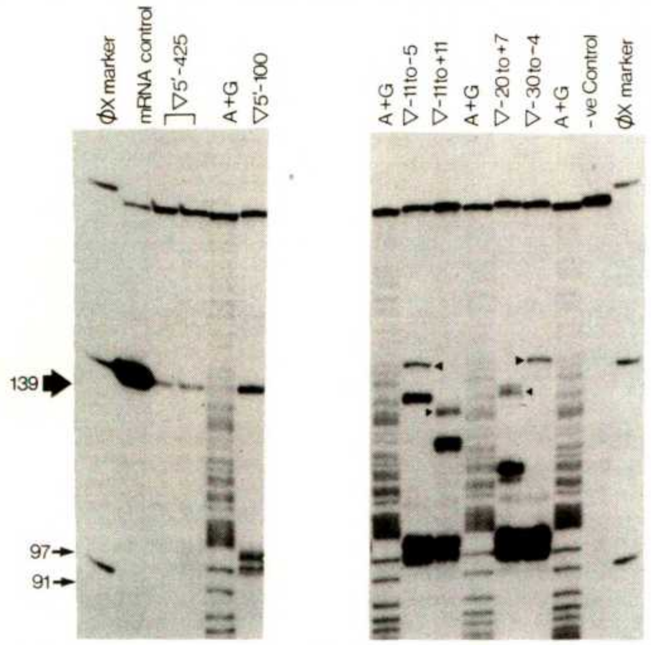

Fig. 3 Transcription of the β-globin gene in mutants at the 3′ boundary of the promoter. HeLa cells were transformed with the 5′ deletion clones ∇ −425 (pβ3′SV*Bgl*II) and ∇ −100 or the 3′ deletion DNA clones ∇ −5 −11, ∇ −11 +11, ∇ −20 +7 and ∇ −30 −4 (see Figs 2, 5) as described in Fig. 1 legend. (See Figs 2 and 5 legends for explanation of the deletions.) The rabbit β-globin mRNAs present in the RNA of those HeLa cells was analysed by S_1 mapping using 5′-end-labelled 221-bp *Bst*NI fragment as indicated in Fig. 1. The S_1 products were loaded onto a 5% polyacrylamide sequence gel and run next to G + A sequence ladders of the 221-nucleotide *Bst*NI minus strand. As an additional size marker, end-labelled ΦX174 × *Rsa*I fragments were used. The numbers on the side indicate products from the natural β-globin 5′ end (139 nucleotides) and RNA products that map within the first exon of the gene (91–97 nucleotides). Besides these two products there are S_1 products labelled with ► in the lanes from the 3′ deletion clones which are derived from an upstream promoter as explained in the scheme of Fig. 4.

determined as above. To orient these 5′ ends with respect to the DNA sequence of the rabbit β-globin gene, a G + A sequence ladder has been run in every third lane on the same gel (Fig. 3).

Sequence requirements for the regions downstream from the ATA box

We have previously analysed *in vitro* transcription using as templates a variety of mutants which lack DNA sequences to the 3′ side of the ATA box. From this we concluded that the DNA sequences downstream from the Goldberg–Hogness box are not necessary for specific *in vitro* transcription because a variety of mutants lacking sequences extending from −20 (or about 4 nucleotides to the 3′ side of the ATA box) to as far as +164 (in the small intron) are transcribed effectively *in vitro*[12]. The *in vivo* cap site is therefore not required; in fact, the RNA polymerase initiates RNA synthesis at about 30 nucleotides downstream from the ATA box, essentially irrespectively of the DNA sequences at the site of initiation. However, extending the deletion to −30, and hence removing the ATA box, eliminates the specificity of *in vitro* transcripts[12]. To determine the effects of the same deletions *in vivo* and in the same cell type, we introduced SV40 recombinants, containing these deletion mutants into HeLa cells. For this purpose we chose the following four mutants: (1) ∇ −11 to −5, which lacks 7 nucleotides between the ATA box and the natural cap site; (2) ∇ −11 to +11 which has the same 5′ break point as the above mutant but which also lacks the natural cap site and a total of 22 nucleotides; (3) ∇ −20 to +7, which lacks 27 nucleotides and all but 4 nucleotides of the 5′ extragenic DNA sequences downstream from the ATA box; and (4) ∇ −30 to −4, which also lacks 27 nucleotides but which, since the deletion is displaced to the 5′ side, lacks the ATA box and retains the natural cap site. All these mutants were constructed in the mutant ∇ 5′ to −100 and therefore lack the DNA sequences upstream of −100.

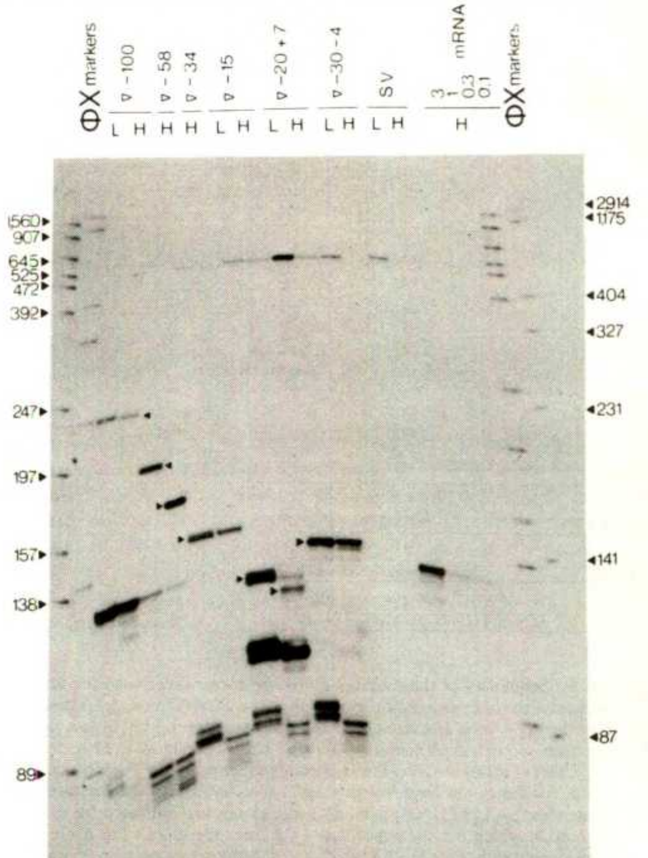

Fig. 4 Transcription of the rabbit β-globin gene from mutant templates lacking DNA sequences at the 5′ and 3′ boundaries of the promoter. HeLa cells were transformed with 5′ deletion clones ∇ −100, ∇ −58, ∇ −34 and ∇ −15 and the 3′ deletion clones ∇ −20 +7 and ∇ −30 −4, as described in Fig. 1 legend. The RNA products from these cells were analysed by S_1 mapping, using a 488-nucleotide 5′-end-labelled *Mbo*II probe that contains 360 bp upstream sequences and the first 128 bp of the 5′ end of the rabbit β-globin gene (−360 to +128). The S_1 reactions were done at 20 °C (L) or 40 °C (H) using 3,000 U S_1 nuclease per sample (0.3 ml). The bands labelled ► are derived from RNA starting at an upstream promoter that is picked up by the *Mbo*II probe, as explained in the lower part of the figure. The bands at +42 to +47 shift at 40 °C lower in the gel because S_1 nuclease attacks the A + T-rich splice junction. To calibrate the hybridization, natural rabbit β-globin mRNA (3.1, 0.3 and 0.1 ng) was hybridized and treated with S_1 nuclease at 40 °C. Relative amounts of rabbit β-globin mRNAs were determined by scanning bands on X-ray film. Numbers are given in Fig. 5. Labelled marker bands on each side of the gel are ΦX174 × *Taq*I (left) and ΦX174 × *Rsa*I (right), respectively. nt, Nucleotides.

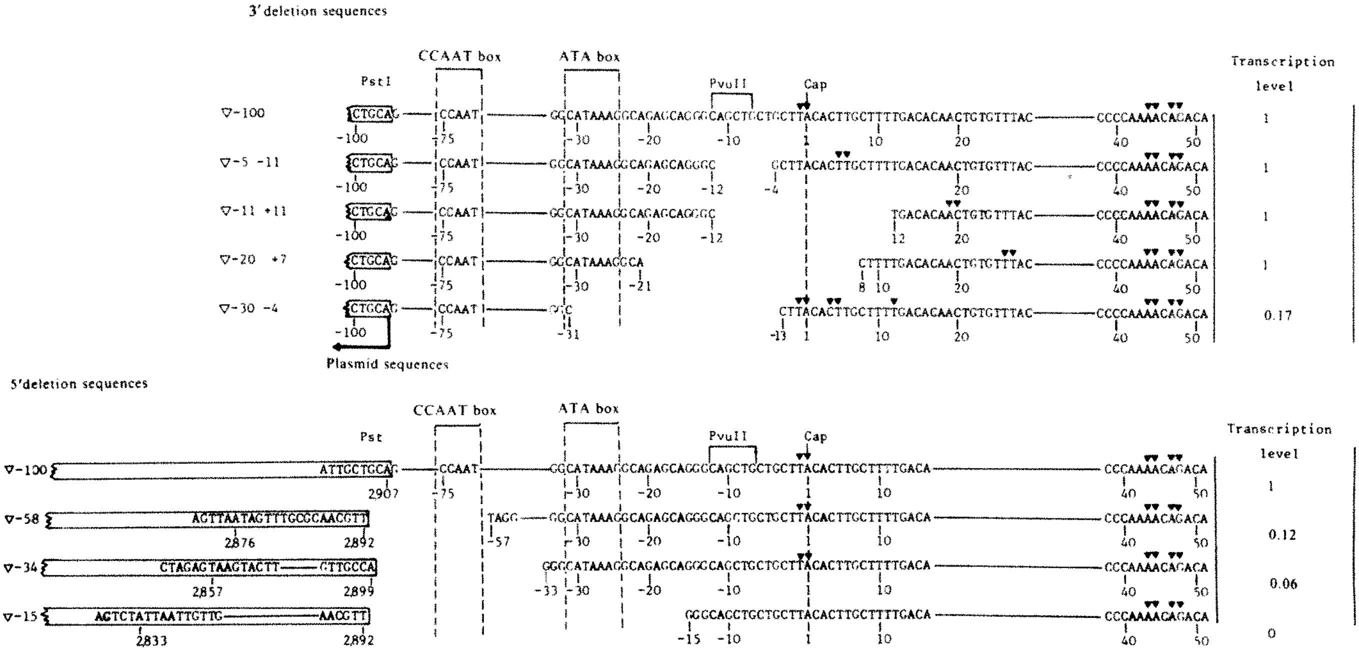

Fig. 5 Sequences of the rabbit β-globin promoter deletions used for SV40-mediated transient expression in HeLa cells. The upper part of the figure gives the relevant areas of DNA (vector–globin junction, CCAAT box, ATA box, cap sequences and start sequences within the gene) of the β-globin clones that have deletions 3' to the ATA box. The size of the deletions are represented by the gap which is left open. As the deletions were constructed from pKSI (Fig. 2), all clones have 5' upstream sequences present to −100 (*PstI* site). The junctions of vector DNA (pAT153) and rabbit β-globin sequences are indicated by the boxed nucleotides. The lower part of the figure gives the important sequences of the β-globin clones that have been deleted 5' to the ATA box. The size of the deletions is again represented by a gap. All the clones have lost the rabbit sequences 5' to the deletion since the construction of these deletions was started from the *BalI* site at −75. The vector sequences (pAT153 DNA) present in the clones are indicated by the sequences in the box. The numbers indicated within the plasmid sequences represent the nucleotide which is now at position −75 from the globin cap nucleotide. The 'transcription level' refers to relative levels of globin mRNA in the HeLa cells transformed with these DNAs, which was determined by scanning the autoradiogram of Fig. 4 with a Joyce—Loebl densitometer. The mRNA signals were compared by assuming that the signal of readthrough RNA starting at an upstream promoter is not influenced by the various deletions in the globin promoter region and was therefore taken as an internal standard signal. ▼ Indicates transcription starts seen in the various clones as concluded from the A + G sequence marker lanes in Fig. 3, and the splice sites located at +44 to +48.

The level of specific transcripts from ∇ −11 to −5, ∇ −11 to +11 and ∇ −20 to +7 is similar to that seen for the control plasmid ∇5' to −100 (Fig. 3). The 5' ends of these mutant transcripts are displaced to the 3' side by essentially the same number of nucleotides as the length of the deletion (Figs 3, 5); we previously found the same result for the transcription of these mutants *in vitro*[12]. The same results have recently been obtained for the SV40 early region *in vivo*[13] and *in vitro*[25]. These data are consistent with the notion that the polymerase is ultimately bound to the ATA box and starts transcription ~30 nucleotides downstream from this site.

The mutant DNA ∇ −30 to −4 which has a deletion of the same size as ∇ −20 to +7, but which lacks the ATA box, shows heterogeneous transcripts, among which is a faint band at the *in vivo* cap site; there are numerous other components. The abnormal RNAs (5' ends at +44 to +48) and 'upstream' plasmid SV40 transcripts are, however, still produced at a similar level to that found for the other mutants. In Fig. 3, a few faint bands are visible in the case of mutant ∇ −30 to −4 that are also visible in the control which contains RNA from HeLa cells transformed with the SV40–pBR328 vector; these are products of incomplete S_1 nuclease digestion which are sometimes obtained from this probe when the S_1 nuclease treatment is performed at 20 °C; note that these products are seen in the lanes from all RNA samples including the RNA from HeLa cells transformed with only the vector.

To eliminate these incomplete digestion products, we treated hybrids formed between a 5'-labelled DNA probe (in this case a 488-bp *Mbo*II fragment; see Fig. 4) and RNA from HeLa cells transformed with the β-globin gene deletion mutants with S_1 nuclease at 20° or 40 °C. Figure 4 shows that the background bands are completely digested at 40 °C in these conditions; in addition however, some cleavage occurs near the 5' end of the perfect hybrids formed with β-globin mRNA and the 5'-labelled probe and these overdigestion products are consequently also seen in the hybrids formed with the transcription products of mutant template ∇ 5' to −100. More important however, the heterogeneous faint bands seen when the mutant template lacking the ATA box, ∇ −30 to −4, is used, are resistant to S_1 nuclease digestion at high temperature and therefore reflect genuine transcripts. As judged from the S_1-resistant DNA fragments, transcriptional starts are found at about five sites on this template (see Fig. 5).

Sequence requirements for the DNA regions upstream from the ATA box

The initial experiments with the SV40–β-globin recombinants showed that the rabbit β-globin gene is transcribed effectively when 1,500, 425 and 100 nucleotides of the 5'-flanking DNA regions are present. There are differences in the level of β-globin transcripts found, but as these three examples have been inserted into different sites on the SV40-plasmids and as the plasmid segments differ, the significance of these differences is not clear. (Note that the template with only 100 nucleotides of 5' upstream sequences is transcribed, if anything, better than the two templates with more 5'-flanking rabbit DNA—there is therefore no compelling evidence at this stage to invoke promoter sequences further upstream than −100.)

To test whether DNA sequences downstream from −100 are required for transcription in this *in vivo* system, we examined the expression of four deletion mutants. A correlation of the transcription efficiency (but see below) with the extent of the 5'-flanking DNA sequences present is justified in these cases as the β-globin gene is present at the same position and in the same orientation with respect to the plasmid and SV40 DNA sequences. The mutant templates we compared are: (1) ∇ 5' to −100, which contains both the CCAAT and ATA boxes; (2) ∇ 5' to −58, which lacks the CCAAT box region but retains the ATA box (together with about 30 nucleotides to the 5' side of this structure); (3) ∇ 5' to −34 which also has the ATA box but only 3 nucleotides upstream from this structure; and (4) ∇ 5' to −15 which lacks both boxes.

As stated above, the mutant template ∇ 5′ to −100 gives a high level of product from the rabbit β-globin gene promoter, together with a high level of abnormal transcripts which give S_1 nuclease-resistant fragments with ends at +44 to +48.

The level of correct product from the ∇ 5′ to −58 mutant is reproducibly reduced when compared with ∇ 5′ to −100 (Fig. 4). As these effects are quantitative, rather than qualitative, we have calibrated the levels of correctly initiated RNA chains within the β-globin gene as a function of the deletion of the 5′ regions of the β-globin gene in two ways. We have first made use of the fact that there is a plasmid or SV40 promoter which initiates RNA synthesis to the 5′ side of the β-globin gene and whose transcripts run into this gene. Since all deletions discussed here are downstream from the promoter, it is reasonable to assume that they will not have a large effect on the frequency of these upstream transcripts. The upstream promoter generates RNAs that form S_1 nuclease-resistant hybrids of a length that in each case reflects the 3′ boundary of the deletion in the DNA template, as explained in Fig. 4. We have therefore used this upstream promoter as an internal control; the S_1 nuclease-resistant bands from the upstream promoter are indicated by a ▼ in Figs 3 and 4. We have compared the levels of products from the two promoters by scanning the autoradiogram; the results are summarized in Fig. 5. Figures 4 and 5 show that the ∇ 5′ to −100 template generates significantly more RNA with the correct 5′ end, relative to the 'plasmid' promoter, than does ∇ 5′ to −58. According to these data, the deletion of the DNA sequences from −100 to −58 caused an eightfold decrease in the level of the correct transcripts. The level of the correct transcripts for the ∇ 5′ to −34 mutant is reduced by another factor of 2. Nonetheless, both these mutant templates produce rabbit β-globin RNA with the correct 5′ terminus, albeit at reduced efficiency. In contrast, ∇ 5′ to −15 shows no detectable product at the correct position. Treatment of hybrids produced with RNA from the HeLa cells transformed with ∇5′ to −15, with S_1 nuclease at both 20 and 40 °C, gives no detectable S_1 nuclease-resistant fragments except the product from the upstream plasmid/SV40 promoter and the abnormal bands at +44 to +48 (Fig. 4). Thus, while the detection of the DNA sequences upstream from the ATA box reduces the level of correct transcripts in the HeLa cells, a deletion that removes the ATA box alters the specificity of transcription. We have confirmed the quantitative difference in the level of β-globin mRNA from the ∇−100, ∇−58 and ∇−34 mutant templates by transfecting HeLa cells with a mixture of the relevant mutant rabbit and the normal human β-globin genes. The result is the same as that in Fig. 4. The correctly initiated rabbit β-globin mRNA is decreased in amount (relative to human β-globin mRNA) when RNA from the ∇−100, ∇−58 and ∇−34 mutant templates is compared; the 'upstream' RNAs referred to above do not vary in amount relative to the human β-globin mRNA (data not shown).

The quantitative effects of deletion of the sequences to the 5′ side of the ATA box may possibly be due to the loss of the CCAAT box region. Inspection of the mutant templates ∇ 5′ to −58 and −34 shows that the plasmid DNA sequences, which replace the sequences deleted, do not contain a recognizable CCAAT structure at the usual 40–50 nucleotides upstream from the ATA box. Similar data have recently been obtained by Dierks *et al.*[24], who analysed the transcription of the rabbit β-globin gene, linked to the HSV TK gene, after the introduction of mutant templates into L cells and the selection of stable TK$^+$ transformats. Their comparison of mutant templates ∇ 5′ to −425, ∇ 5′ to −76 and ∇ 5′ to −68 revealed a high level of the correct β-globin transcripts in the former two cases, but a significantly reduced level in ∇ 5′ to −66, that is, on deletion of a region containing the CCAAT box. The ∇ −66 mutant is adjoined to the plasmid DNA sequences by a dG-dC linker tract that is absent in ∇ −76. It is therefore also possible that the difference between the results obtained with these two mutants is influenced by the dG-dC tract[24]. A requirement for the −80 region for the expression of the human α-globin gene on an SV40 vector has also been demonstrated (P. Mellon, V. Parker, Y. Gluzman and T. Maniatis, personal communication). It seems that the CCAAT box region may be involved in the efficiency of generation of specific transcripts from the rabbit β-globin promoter. Proof of this awaits the specific alteration of the CCAAT sequence by single base deletion or point mutation experiments.

Conclusions

The results obtained with the rabbit β-globin gene (this work and refs 12, 25) have aspects in common with observations made recently on the sea urchin histone genes after microinjection into *Xenopus* oocytes and the SV40 early genes *in vivo*, but there are also significant differences. First, the ATA box is clearly required for the fixing of the transcriptional start sites of the β-globin gene[12] and the SV40 early genes *in vitro*[25] and for all three genes *in vivo* (this work and refs 13, 15). This site of initiation is apparently discrete and is located ∼30 nucleotides downstream from the first nucleotide (CATAAAG) of the box. This precision is not influenced *in vivo* (this work) or *in vitro*[12] by the deletion of essentially all the 5′-extragenic β-globin gene sequences upstream from the ATA box (as in ∇ 5′ to −34) or all the sequences from the ATA box to past the natural cap site. Thus the positioning of the start site is independent of the CCAAT box region *in vivo* and of the presence (as in ∇ −11 to −5) or absence (as in ∇ −11 to +11) of the natural cap site. These results are broadly similar to those obtained for the SV40 early region[13].

Deletion of the ATA box generates RNAs with heterogeneous 5′ ends for the sea urchin histone H2A gene[14], SV40 early genes[13] and the rabbit β-globin gene (this work) if the DNA sequences further upstream from the ATA box are present. In the case of the SV40 early region, the amount of early RNA produced does not seem to be strongly influenced[13], while the ATA box deletion in both the histone[14] and β-globin (this work) genes is a strong down mutation (Figs 3, 5). It is significant that these heterogeneous RNAs are not observed when the β-globin DNA sequences lying between −100 and the ATA box are also deleted, as in mutant ∇ 5′ to −15. It is therefore plausible that the CCAAT box region is involved in the promotion of these heterogeneous RNAs when the ATA box is lacking and that their absence in transcripts derived from ∇ 5′ to −15 results from the absence of the CCAAT box.

The results for the β-globin gene differ significantly from those for the SV40 early region and sea urchin histone genes, as sequences far upstream from the β-globin gene are not required to generate a high level of β-globin mRNA in the SV40-based system. For both the histone H2A gene[16] and the SV40 early region[13], sequences located about 200–300 nucleotides upstream are essential for RNA synthesis. This does not appear to be the case for the rabbit β-globin gene since mutant ∇ 5′ to −100 is transcribed as well as, or better than, ∇ 5′ to −425. There is evidence, however, that DNA sequences near the CCAAT box (which is at −75) are involved in promoting high-efficiency transcription from the rabbit β-globin gene cap site (this work and ref. 25). The SV40 early region contains two putative CCAAT (both (CTAAC) boxes at 80 and 101 nucleotides upstream from the first cap site[21], and deletion of this region causes a decrease in the level of early gene expression. In contrast, the deletion of this region in the sea urchin H2A histone gene stimulates RNA synthesis[14]. When considering the effect of DNA sequences far upstream, note that the results with the β-globin gene have been obtained on templates carrying the SV40 72-bp repeats that are absolutely required for SV40 early gene transcription and which constitute the upstream sequences of the SV40 early region. Note also that a region of SV40 which contains the 72-bp repeat is required to obtain a high level of transcription of the rabbit β-globin gene in HeLa cells[20]. It is therefore possible that this SV40 region is supplanting the requirement for rabbit β-globin upstream sequences; a corollary of this is that these rabbit sequences, if they exist, must not be present on the 4.8-kb genomic *Kpn*I segment which contains the rabbit β-globin gene, since this segment is expressed at a 100-fold level in the absence of the SV40 moiety[20]. We are currently testing whether such modulator sequences exist further from the β-globin gene. If the SV40 sequences do have this role, then it is significant that this function can be provided by SV40 sequences located at variable distance (~3,200–4,400 bp) and in either orientation (at least in 5′ to −1,500 and ∇ 5′ to −425) to the β-globin gene. This is not the type of effect expected from a classical promoter-type sequence. Remember, however, that evidence exists for effects on globin gene expression of deletions far from the genes affected *in vivo* in man (ref. 26 for example). The relevance of these effects to promoter sequences is at present unclear, as is the relevance of the effects observed in the current type of experiment to the problems of promotion of RNA synthesis from the rabbit β-globin gene in its natural chromosomal location in an erythroblast.

Finally, note that in all the systems discussed here (sea urchin histone genes, SV40 and rabbit β-globin genes), several promoters are being utilized on the same DNA template. This might complicate interpretation: for example, transcription from an upstream promoter might influence RNA synthesis from the promoter being studied, in our case the rabbit β-globin gene promoter. At present insufficient data are available to evaluate the extent of these problems.

We thank F. G. Grosveld for helpful suggestions and W. Schaffner for advice on the HeLa cell system. C.K.S. was the recipient of a Jane Coffin Childs Fellowship. This work was supported by the British MRC.

Nature of the shells of NGC1344

D. Carter, D. A. Allen & D. F. Malin

Anglo-Australian Observatory, PO Box 296, Epping,
New South Wales 2121, Australia

Various theories have been proposed to account for the origin[1,2] of the low surface brightness features resembling thin shells seen in projection around some otherwise normal elliptical galaxies[3]. It has proved impossible to discriminate between these models owing to the lack of quantitative data on the nature of the shells. Here we present broad-band optical (*B, V, R*) and near-IR (*J, H*) photometry of one of the shells to determine their constitution and place constraints on their mode of formation. The colour indices derived suggest that the shell comprises a population of stars, perhaps bluer than the main body of the galaxy. There is no evidence for recent star formation. Our results favour dynamical models for the formation of the shells, perhaps from recent mergers of disk galaxies with the elliptical.

The shells are visible on high-contrast derivatives of deep IIIaJ plates taken with the UK Schmidt and Anglo-Australian telescopes (AAT). For quantitative photometry we obtained images with a linear panoramic detector. The instrument available was the UCL Image Photon Counting System (IPCS) at the AAT. The large-scale spatial nonuniformities are worse than a conventional photographic plate and, at the time of our observations, were time variable, perhaps because of the effect of ambient temperature variations on the electronics, so that their removal by flat fielding is not perfect. Also, because of the finite frame rate of the IPCS, data arrival rates above about 30 photons arc s^{-2} s^{-1} will cause saturation. This limits the dynamic range of the system, and standard stars must be very faint. These factors limit the precision of the optical photometry; nevertheless, quantitative data can be obtained.

IPCS images of an area 110×90 arc s containing part of the boundary of the outermost shell to the north-west of NGC1344 were obtained with the AAT on the night of November 11 1980. Figure 1 illustrates the position of the IPCS field. Images of the faint globular cluster Hodge 11 were also obtained, this cluster contains faint electronographic sequences by Walker[4] and unpublished photometry by Bessell and Gascoigne. Table 1 lists the observations made.

The data were flat-fielded with a combination of exposures of the inside of the dome and the twilight sky. Residual nonuniformities in sensitivity, at the level of 1% in the line increment direction of the IPCS (corresponding to the declination direction on the sky) were removed by fitting a low-order polynomial to the sky background to improve the cosmetic appearance of the images.

To establish zero points the intensity of several star images in the Hodge 11 field was integrated, in a circle of some 5 arc s diameter, and the background level determined from an annulus around each was subtracted. The resultant intensity was compared with Walker's[4] electronographic magnitudes for *B* and *V*, and in *R* with magnitudes predicted from *V* and $B-V$ using the colours for giants tabulated by Bessell[5]. Hodge 11 was assumed to be unreddened. This procedure yielded zero points internally accurate to ~0.08 in *B* and *V*, and 0.15 in *R*. Extinction coefficients typical for Siding Spring Mountain on a photometric night were adopted. Each of these assumptions will

Table 1 IPCS observations

Object	Filter	Exposure time (s)	Mean wavelength (μm)
NGC1344 shell	*B*	6,000	0.45
	V	6,000	0.55
	R	8,000	0.66
Hodge 11	*B*	300	0.45
	V	300	0.55
	R	500	0.66

Conditions were photometric for the whole night.

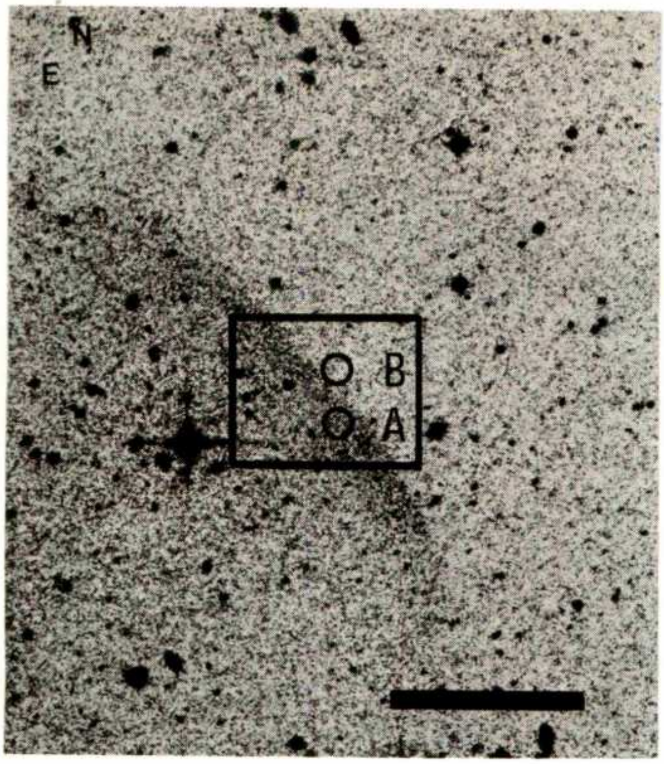

Fig. 1 The north-west shell of NGC1344. IR photometry of the areas indicated by circular apertures A (shell) and B (sky) was obtained. Two-dimensional photometry in B, V, and R was obtained of the area within the rectangle. Scale bar, 2 arc min.

contribute uncertainties of 0.03 mag or less to the derived zero points.

Although the B optical image was much more uniform than V and R, the shell was clearly visible on all three. The shell surface brightness was measured by integrating the intensity in circular apertures of diameters 5–14 arc s on the brighter part of the shell, near the edge, and subtracting from it the intensity in a similar aperture just off the shell, separated from the first aperture in RA only (that is, the direction perpendicular to that along which a polynomial was fitted). This was done at several points along the shell edge, and particularly at the point coincident with the IR aperture (see below and Fig. 1).

Because of the brightness distribution of the shell, conventional IR photometry, using symmetrically placed sky reference beams, is extremely difficult and would, in any case, require a much larger beam throw than was available. We therefore made our observations using the d.c. electronics[6] of the IR photometer spectrometer on the AAT. The telescope was driven back and forth between the shell and a point 36 arc s north on the sky, completing a cycle shell–sky–shell in typically 5.6 s At this frequency we could approach quite closely the expected photon shot noise at J. The stronger and highly variable sky emission at H did not allow such precision. A slight improvement in the precision was obtained by editing from the data any portion where successive measurements (whether of shell or sky) differed by more than 10 times the expected photon shot noise.

Our basic measurements were made with a 14-arc s diameter circular aperture centred at position A in Fig. 1. This and the sky position, B, were chosen to avoid all stars and galaxies visible on a contrast-enhanced Schmidt plate or on the IPCS images. To check that contamination from invisible sources was not influencing our data we made additional observations at J with a 10-arc s aperture, and in a second position with the 14-arc s aperture. The consistency of the measured surface brightnesses gives us confidence that our measurement refers to the shell alone.

At J the shell was 8×10^{-4} of the minimum sky brightness, which occurred near 3 a.m. LT. At H the corresponding value was 1.5×10^{-4}.

Measuring the surface brightness in B, V and R at several points along the shell edge yields:

$B-V=1.1\pm0.25$ mag
$B-R=1.2\pm0.3$ mag

Errors due to sky subtraction uncertainties dominate over zero point errors. Surface brightness measured at position A in Fig. 1 are:

B (0.45 μm) $=26.5\pm0.2$ mag/arc s^{-2}
V (0.55 μm) $=25.1\pm0.2$ mag/arc s^{-2}
J (1.25 μm) $=23.93\pm0.10$ mag arc s^{-2}
H (1.65 μm) $=23.43\pm0.17$ mag/arc s^{-2}

$B-J=2.57\pm0.22$ mag
$B-H=3.07\pm0.27$ mag

Because of the long baseline and the lower errors we would rely more on $B-J$ and $B-H$ than anything else. All of the measured colours are consistent with those of stars of spectral type between G5 and K4. However, if we are sampling a composite system, we will record bluer stars in the optical than in the IR. Persson *et al.*[7] report IR and optical photometry for several composite systems. Most are redder than the colours we observe for the shell of NGC1344. For the nucleus of NGC1344 they obtain:

$B-J=3.13$ (corrected to match our J filter)
$B-H=3.84$

For a small (7 arc s diameter) patch in the galaxy ~50 arc s north of the nucleus we measure:

$B-V=0.85\pm0.15$ mag
$B-R=1.60\pm0.15$ mag

Thus the shell near NGC1344 is bluer than the main body of the galaxy.

What do the shells consist of? Observations at 21 cm by A. E. Wright, D.F.M. and D.C. (unpublished) give an upper limit of $7.7\times10^{8}\ (50/H_0)^2\ M_\odot$ for the neutral hydrogen content of NGC1344 in a 14-arc min beam, which includes the outer shell. Less stringent upper limits were also placed on the H I content of some other shell galaxies. Long slit spectra covering the inner shells of NGC1344 and NGC3923, obtained by P. Quinn and D.C. show no detectable line emission at Hβ or [O III], even after many thousands of seconds integration time. We conclude that the shells consist almost entirely of cool stars. The colours are consistent with a population of stars which is bluer than the main body of a normal elliptical. Of the systems studied by Frogel *et al.*[8], some of the bluer lenticulars, such as NGC404 (ref. 8) and NGC5102 (ref. 7), have similar colours. Quinn[2] shows that features like these can form from mergers of dynamically cool systems, such as disk galaxies, with an elliptical galaxy, so it is perhaps not surprising that the shells have the colours of disk galaxies.

The measured B surface brightness implies a total luminosity of the outer shell of $3\times10^{8}\ (50/H_0)^2\ L_\odot$.

A more remote possibility is that the shells consist of dust, reflecting light from the main body of the galaxy. However, unless the dust grains were abnormally large, their scattering properties would render the shells bluer than the galaxy by at least 1.5 mag over a baseline from B to H. This is ruled out by the data. Also it has been shown[3] that a substantial optical depth would be required to produce the observed shell surface brightnesses, and unless the dust to gas ratio is abnormal, this is not consistent with the limit on the H I content of the galaxy.

In conclusion, the shells apparently consist of stars, probably with the colours of a disk population rather than an elliptical population, but not so blue that they might have been formed very recently, for example in a hot galactic wind. Thus our data support dynamical models for the formation of the shells[2], rather than models in which stars are formed in a galactic wind[3], which would predict colours for the shells some 0.5 mag bluer in $B-V$, and therefore some 1.6 mag bluer in $B-J$, than the main body of the galaxy.

A possible link between the rotation of Saturn and its ring structure

F. A. Franklin, G. Colombo & A. F. Cook

Harvard-Smithsonian Center for Astrophysics, 60 Garden Street,
Cambridge, Massachusetts 02138, USA

We present here evidence that two previously unidentified, yet conspicuous gaps in Saturn's rings lie at distances corresponding to 2/3 and 4/3 of the planet's rotation period. Gaps such as these can be produced in a ring of large bodies or small uncharged particles only by a non-axisymmetric gravitational field (both of the above can be associated with the $l=m=3$ harmonic), a fact that is relevant to models of planetary interiors.

The 'classical' picture of the radial structure of Saturn's rings explains its narrow gaps and boundaries as the consequence of resonant perturbations with certain satellites, in particular, Mimas, Titan and Iapetus. Thus, for example, the inner part of the prominent Cassini division lies at a distance from Saturn (117,900 km) where the orbital frequency of residual ring particles is essentially twice that of Mimas[1]. Two recent developments have brought a new perspective to the association between certain ring divisions and satellite resonances. The first is a study by Goldreich and Tremaine[2] of a mechanism whereby satellites can produce gaps that may eventually achieve widths of hundreds, possibly thousands, of kilometres, while the second is the data provided by the Voyager mission concerning the locations, dimensions and sheer number of ring features[3]. These new data will require a careful study when more precise positions are provided by Voyager 2. Aspects of this analysis are underway with the preliminary result that many ring features in portions of the ring having low optical thickness ($\tau \lesssim 0.2$) show a clear correspondence with satellite resonances. There are, however, obvious exceptions in which large gaps fail to have any association with moderate-to-strong satellite resonances. We supply here a possible explanation for two divisions, and specifically for the conspicuous gap, some 200 km wide, located in the outer part of ring C, 86,700 ± 700 km from the centre of Saturn. Ring particles at this distance have mean motions one and one-half times the value corresponding to Saturn's 10 h 39.4 min rotation period[4] and the planet can act to produce a gap, several hundred kilometres wide, just as a satellite would, only if its mass distribution is non-axisymmetric. (The ellipticity of the Earth's Equator is one such example.) If we suppose asymmetries to be present in Saturn, then the disturbing potential[5] can be written

$$V_{lm}=\frac{\mu_s a_s^l}{a^{l+1}}\sum_{p=0}^{l}F_{lmp}(i)\sum_{q=-\infty}^{\infty}G_{lpq}(e)S_{lmpq}(\tilde{\omega},\lambda,\Omega,\theta_s) \qquad (1)$$

where l and m are usual subscripts arising in an expansion in spherical harmonics, p and q are introduced by the inclination and eccentricity functions, $F(i)$ and $G(e)$ which allow V to be expressed in terms of orbital elements. The a refers both to the equatorial radius of Saturn, s, and the semimajor axis of a ring particle and $\mu_s \equiv GM_s$. The quantity S_{lmpq} contains the harmonic coefficients, C_{lm} and S_{lm} that are associated with cos and sin terms whose angular argument is

$$[\lambda(l-2p+q)-m\theta_s-q\tilde{\omega}-(l-m-2p)\Omega] \qquad (2)$$

where λ is the mean longitude, $\tilde{\omega}$ and Ω are the longitudes of pericentre and node, respectively, and θ_s is the longitude on Saturn associated with a given harmonic so that $\dot{\theta}_s \equiv \omega_s$ is the spin rate of 810.7601° day^{-1} (ref. 4). At present we consider only orbits in the equatorial plane so that $i=0°$, whence it follows that for $F(i=0°)\neq 0$, $l-m=2p$. The function G is proportional to $e^{|q|}$, where e is the eccentricity of a ring particle. The case $q=0$ corresponds (see equation 2) only to synchronous rotation, that is $\dot{\lambda}\equiv n=\omega_s$, where n is the mean motion. This case—the analogue of the 1:1 resonance of the Trojan asteroids—produces effects that must be analysed differently from those arising at other resonances[5]. Synchronous rotation, presumably not by coincidence, lies in the outer part of ring B where $\tau \gg 1$. The orbital behaviour of (non-colliding) particles near the synchronous distance, d, is well known[5] so that the surface brightness can apparently show an azimuthal dependence over a narrow annular region centred on d.

Table 1 Correspondence of ring features and certain resonances

Resonance		a_{obs}	a_{calc}	Width	n/n_s
		(10^5km)		(km)	
Mimas, 2:1		1.179	1.1754	450	
Titan 'apsidal'		0.773	0.7765	200	
m	q				
2	−1	0.732	0.7201	—	2:1
3	+1	1.361	1.3607	~30	3:4
3	−1	0.867	0.8637	250	3:2

The first, a 2:1 ratio between local mean motion and that of Mimas and the second, equality of local apsidal precession frequency and the mean motion of Titan, provide characteristic values of the positional accuracy of Voyager 1 measurements. Final three (first of these is a boundary, not a gap) are associated with the non-axisymmetric gravitational field of Saturn. n/n_s is the ratio of the orbital frequency at resonance to the planet's rotation rate[4].

The cases, $q=\pm 1$ are the equivalent of the $n/(n+1)$ orbit-orbit resonances. As is evident from the Lagrange planetary equations, forcing terms associated with them contain $e^{|q|-1}$ and are therefore stronger than higher order commensurabilities. We consider only the $|q|=1$ case so that, for $i=0°$, the time derivative of equation (2) yields

$$n=\frac{m\omega_s \pm \dot{\tilde{\omega}}}{m\pm 1} \qquad (3)$$

where, apart from $l-m=2p$, $m\leq l$ is the only remaining restriction on equation (3).

In the saturnian case, the first—and presumably the strongest—nonaxisymmetric term (given by the C_{22} or S_{22} coefficients) produces, apart from the case at the synchronous distance just mentioned, no resonance lying within the ring system. However, the $q=-1$ case, whence $n=1591.70°\ \mathrm{day}^{-1}$ and $a=72{,}010$ km lies just inside the inner boundary of ring C, measured by Voyager 1 at 73,200 ± 700 km. (All these calculations use $a_s=60{,}330$ km, $J(\propto C_{20})=0.0244488$ and $K(\propto C_{40})=0.0034375$ and $\mu_s=3.79209\times 10^{22}$.)[6] Two cases where the identification seems likely arise when $m=3$, that is $n=(3\omega_s-\dot{\tilde{\omega}})/2$ and $n=(3\omega_s+\dot{\tilde{\omega}})/4$. Calculations (Table 1) place the former at 86,370 km, the latter at 136,070 km and, in each case, especially the former, a prominent ring gap is nearby. A caveat remains because systematic errors as large as ±700 km (ref. 7) attend the positional measures made by Voyager 1 and the accurate Voyager 2 results require reductions not yet complete. To offset this uncertainty, we have compiled in Table 1 predicted and measured locations for two strong satellite resonances whose identifications are well-established, together with those, just considered, that we associate with the planet's rotation.

It seems premature to examine evidence linking less conspicuous gaps in ring A with larger values of m. For future efforts

0028–0836/82/020128—03$01.00

and because much 'fine structure' has been detected in the Cassini division[7], we list in Table 2 selected resonance locations arising from non-axisymmetric terms up to $m = 13$. The stellar occultation experiment of Voyager 2 will provide the observational material for comparison.

Using the analysis of Goldreich and Tremaine[2], we can estimate the magnitude of the C_{33} coefficient required to produce the large gap in outer C ring by replacing the disturbing function due to an exterior satellite by one appropriate for the non-axisymmetric mass distribution of Saturn. For the case $i = 0°$ and $|q| = 1$, the disturbing function (1) can be written.

$$V^{lm}_{|q|=1} = (-)^{(l-m)/2} \frac{\mu_s}{\pi^{1/2} a_s} 2^{m-1} \left(\frac{a_s}{a}\right)^{l+1} \Gamma\left(\frac{l+m+1}{2}\right) \times (l - 2qm + 1) e S_{lmpq} \qquad (4)$$

where Γ is the gamma function and S_{lmpq} contains the C_{lm} and S_{lm} coefficients. Equation (4), when combined with the development of Goldreich and Tremaine, shows that a combined harmonic coefficient, $(C^2_{33} + S^2_{33})^{1/2} \gtrsim 2 \times 10^{-10}$ is sufficient to generate the observed gap width is the process[2] can operate essentially for the age of the Solar System. As there is no evidence favouring such long-term operation, it is useful to see if the lower limit can be raised. Values of $(C^2_{33} + S^2_{33})^{1/2}$ must be large enough to ensure that a gap can be cleared, thanks to angular momentum transport, in the presence of continuing viscous diffusion. The relevant equations have been derived by Goldreich and Tremaine[8], whence the most stringent condition is

$$(C^2_{33} + S^2_{33})^{1/2} \gtrsim \frac{1}{3} \left(\frac{\nu}{\Omega_K r^2}\right)^{1/2} \qquad (5)$$

where ν is the kinematic viscosity and Ω_K the local keplerian angular velocity. The former has recently been derived[7] from observations, made by Voyager 1, of the Cassini division, $\nu = 170 \pm 80\ \text{cm}^2\ \text{s}^{-1}$, which approximately accords with theoretical estimates[2]. If we assume that the same value of ν applies in parts of the ring having larger optical thickness, then the right-hand side of equation (5) yields $\sim 3 \times 10^{-8}$ as the appropriate limit.

The gap at 1.361×10^5 km in the outer part of ring A is produced by the same $l = m = 3$ harmonic, with $q = +1$ rather than -1 (although higher harmonics may contribute to both). Equation (4) indicates why it is so much narrower (see Table I). In addition to the difference in the saturnicentric distance of the two, for the outer resonance, the factor $(l - 2qm + 1)$ drops by a factor of 5.

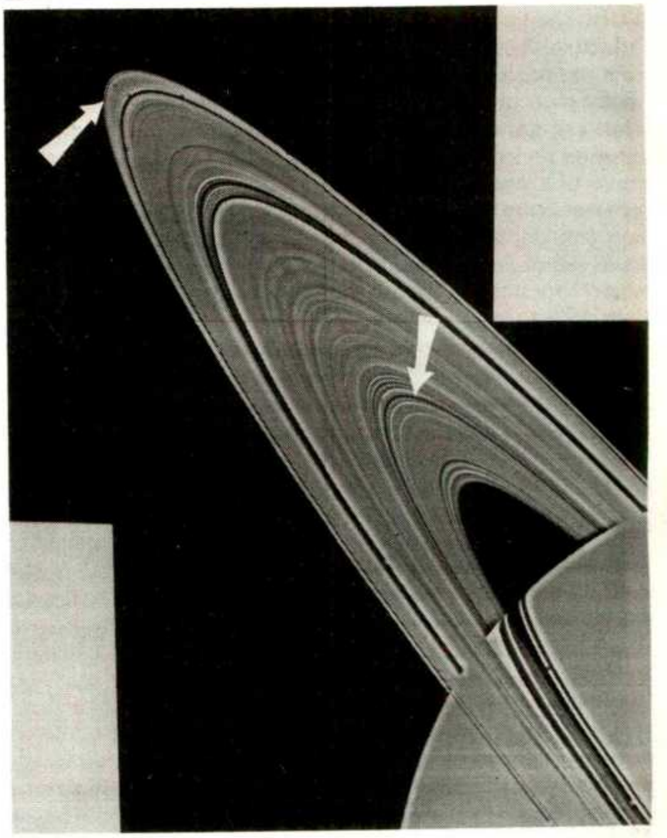

Fig. 1 Ring system from Voyager 1. Arrows mark the two gaps that can be accounted for if Saturn has an $l = m = 3$ harmonic.

Following the Saturn encounter of Voyager 2, a more detailed examination of the positions and widths of all ring features, especially in regions of low optical thickness, is necessary. We shall also need an equally careful review of the mechanism of gap formation to infer more precise values for the harmonic coefficients. There now seems to be some evidence that Saturn's gravitational field does contain at least the (3,3) harmonic. Although it is tempting to suppose that the (2,2) term, with its strong resonance just inside the inner ring C boundary is responsible for the truncation of that ring, how this happens is not clear. If the ring system once did extend closer to Saturn, into the D-ring region, then were the planet to have a substantial (2,2) term, a broad gap near 72,000 km could be produced, with its outer boundary at the observed truncation of the C ring. However, we would apparently still require an additional process[9] to reduce the surface density inside that resonance. In this context, we should note that the effective inner boundary of Jupiter's ring lies at a distance corresponding to the $l = m = 3$ resonance, or, where $2n = 3\omega_J - \dot{\omega}$. Adoption of $\omega_J = 870.5443°\ \text{day}^{-1}$ (corresponding to a period of 9 h 55 min 29.37 s), $J = 0.02208$, $K = 0.00244$ and $R_J = 71430$ km shows this resonance to be located at 1.227×10^5 km, whereas, although the ring can be faintly traced nearly to the jovian cloud tops, measurements place the inner edge of the bright portion (viewed in backscattered light) at $1.228 \pm 0.007 \times 10^5$ km (ref. 10). The influence on particle orbits that we attributed to tesseral harmonics of the gravitational field might instead result from the primary's inclined, displaced magnetic field. As for Saturn, the outer ring boundary seems to be established by a small satellite.

Table 2 Positions (in optically thin regions) of additional strong resonances associated with higher harmonics of Saturn's field

m	q	a_{calc}	n/n_s
4	+1	1.3037	4:5
5	+1	1.2690	5:6
8	+1	1.2159	8:9
9	+1	1.2060	9:10
10	+1	1.1980	10:11
11	+1	1.1915	11:12
12	+1	1.1860	12:13
13	+1	1.1814	13:14

Cassini division, where many narrow gaps appear[7], stretches from ~ 1.177 to $\sim 1.210 \times 10^5$ km. Precise positions from Voyager 2 are necessary for a detailed comparison.

It seems unlikely that harmonic coefficients with $m \neq 0$ refer to the shape of Saturn's (probable) rock–ice core. However, Stevenson[11] has proposed a new interior model with three distinct layers, in addition to the core, that can account both for the planet's unexpectedly weak magnetic field and its excess heat flux. The model's outermost layer consists of an envelope of molecular H_2 and He, with the latter somewhat depleted. The existence of metallic H characterizes the next layer which is inhomogeneous because of the limited solubility (dependent on temperature and pressure) of He in metallic H. Deeper, droplets of He eventually dissolve to form a much more homogeneous layer above the core. The inward migration of He releases gravitational energy and might inhibit convection, but, for our purposes, the vital point is the existence of several distinct layers. The likelihood that various instabilities can exist on the surfaces of these layers such that their interfaces assume a wavy form was suggested by R. Smoluchowski. In a nonlinear regime, denser parts of the fluid will collect near the troughs, while the crests can grow by buoyancy to reinforce the wave. Although diffusion seeks to eliminate such waves, they may, in a poorly convective layer, persist for a long time or be regenerated. If such waves are the source of Saturn's gravitational asymmetries, then concomitant ring features may well vary to some time scale—all of which means that any estimate of $(C_{33}^2+S_{33}^2)^{1/2}$, but perhaps not its existence should be treated cautiously. As an alternative to instabilities at layer interfaces, one might consider an interior model possessing large scale convective cells that develop and sustain non-axisymmetric mass distributions—presumably over extended periods of time.

We thank Drs R. Smoluchowski, I. Shapiro and J. Cuzzi for useful discussions. Aspects of this study were funded by NASA under contract NAS 7-100 with the Jet Propulsion Laboratory.

Radiation effects and the leach rates of vitrified radioactive waste

W. G. Burns, A. E. Hughes, J. A. C. Marples, R. S. Nelson & A. M. Stoneham

Atomic Energy Research Establishment, Harwell, Didcot,
Oxon OX11 0RA, UK

There is much concern that long-lived radioactive elements incorporated in glasses for the disposal of highly active nuclear waste might eventually return to the environment. The most important mechanism begins with leaching of the glass by groundwater and a leach rate, usually based on laboratory tests of simulated vitrified radioactive waste, has been used as the basis of analyses of the radiological safety of a waste repository[1–3]. The possibility that radiation damage to the glass from the products of nuclear decay could change the leach rate has been studied both by the incorporation of active elements in the glass and by irradiation from external sources. The most important contribution to radiation damage comes from the recoil nuclei during α decay[4]. Typically the recoil nucleus has a kinetic energy of ~100 keV and displaces >1,000 atoms in the glass. Experiments which simulate this damage by incorporating short-lived α-emitting isotopes such as ^{238}Pu into the glass have not shown significant increases in leach rate at doses equivalent to $>10^{18}$ α decays g^{-1} (refs 5–9). Figure 1 shows that for wastes considered in the UK this corresponds to a time after vitrification of at least 10^3–10^4 yr. Recent work with ion beams inducing the radiation damage[10–12] has suggested that large increases (up to a factor of just over 50) in leach rate will occur after a critical dose of radiation from the α-decay processes. In addition, experiments in which the leaching solution is irradiated with γ rays[13–15] have shown that radiolysis effects in the water can increase the leach rates of glasses. We present here new data and calculations which relate these studies to the conditions expected in a real waste repository. Our analysis is described in more detail elsewhere[16,17].

Dran *et al.*[10,11] irradiated glasses and crystalline minerals with 200-keV Pb ions and found that an enhanced leach rate occurs above a critical fluence of $\sim 5\times10^{12}$ ions cm^{-2}, which corresponds to the dose at which the individual damage zones (each of lateral extent ~10 nm) produced by the Pb ions overlap. Such effects have been observed before, for example, in ion-irradiated garnets[18]. One expects similar overlap of damage zones to occur in a glass containing α emitters at a dose of $\sim 10^{18}$ decays g^{-1}.

Table 1 Leach tests on samples of glass 189* doped with $^{238}PuO_2$

			Holding temperature (°C)	
		First year	50	170
		Subsequent years	20	20
Date	Dose (α-disintegrations g^{-1})	Equivalent time (yr)	Leach rates (mg cm^{-2} day^{-1})	
November 1975	0.89×10^{18}	7,000	1.6	1.5
February 1977	2.0×10^{18}	250,000	2.3	2.3
March 1977	2.1×10^{18}	300,000	2.4	2.2
November 1977	2.7×10^{18}	500,000	2.3	2.6
July 1978	3.3×10^{18}	700,000	2.3	2.5
January 1981	5.5×10^{18}	1,400,000	3.2	2.7
February 1981	5.6×10^{18}		3.0	

The equivalent times assume 0.5% of the plutonium and 0.25% of the uranium originally present in Magnox fuel go into the waste. The fuel is assumed to be reprocessed after 6 months out of the reactor. Leach rates were measured by the Soxhlet method, in which the sample is in contact with frequently changed distilled water at 100 °C. The initial Soxhlet leach rate expected for undoped glass of this composition is 1.3 ± 0.2 mg cm^{-2} day^{-1}.

* The composition of this glass in wt% is SiO_2: 41.5; B_2O_3: 21.9; Na_2O: 7.7; Li_2O: 3.7; simulated waste product oxides: 25.2.

Each incident 200-keV Pb ion in the ion beam experiments produces $\leq 3{,}000$ displacements. The irradiated region has a depth of 50 nm so that at a critical fluence of 5×10^{12} ions cm^{-2} the average number of displacements is not more than 3×10^{21} cm^{-3}. We calculate that each α decay produces 1,380 displacements so the critical fluence is equivalent to 2.2×10^{18} α decays cm^{-3}. For a typical glass density of 2.6 g cm^{-3} this is 8.5×10^{17} decays g^{-1}. Dran *et al.*[11] quote $\sim 2\times10^{18}$ decays g^{-1} as the equivalent dose to a Pb ion fluence of 5×10^{12} cm^{-2}. Their method is based on an equivalent number of heavy ion tracks crossing unit surface area. However, whichever approach is used the appropriate figure is clearly $\sim 10^{18}$ decays g^{-1}.

Table 1 shows recent results from work at Harwell on samples of UK glass 189 which have been doped with 5 wt% of $^{238}PuO_2$. Regular leach tests of these samples in distilled water using the Soxhlet test have been made since their manufacture in 1975. Only modest increases in leach rate have been observed even after 5.6×10^{18} α decays g^{-1}. The PuO_2 may not be completely homogeneously dispersed in these samples, but it is believed that most of it is in solid solution in the glass as would be the case for the α-emitting isotopes in real vitrified waste. There is no evidence of a large increase in leach rate as found by Dran *et al.* One of these samples has now also been tested in a 250 g l^{-1} NaCl solution at 100 °C as used by Dran *et al.* and showed an increase by a factor of only 1.2 over an unirradiated sample. Furthermore the leach rates were an order of magnitude smaller in the NaCl solution than in distilled water.

We therefore believe that the large effects noted by Dran *et al.* do not occur in the simulations using α emitters, which, of course, are accelerated versions of the effects that will actually occur in practice. In trying to rationalize these results we have considered possible effects of dose rate[16]. Simulations with α emitters are carried out at rates 10^4–10^5 times higher than those pertinent to a real waste repository at times $\gtrsim 100$ yr, whereas the ion beam experiments are accelerated by a factor of 10^{10}–10^{11}. If r cm^{-3} s^{-1} is the rate of damaging events and v cm^3 the volume of a damaged zone created by one event (that is, by a single incident ion or single recoil nucleus), then the time required to reach a stage where the zones overlap is $t_{\text{crit}} \simeq (rv)^{-1}$.

Obviously if an individual zone recovers (anneals) in a time short compared with t_{crit}, overlap of zones is not reached. By extrapolating data obtained at Harwell on the annealing of density change of the glass and the release of irradiation-induced stored energy on heating, we estimate[16] that the mean recovery time of a damaged zone is in the range 10^4–10^7 s between 25 and 200 °C. With $v \sim (10\ \mathrm{nm}^3)$ we estimate that $t_{crit} \sim 10$ s for the ion beam experiments, $\sim 10^8$ s for simulations with α emitters and $\sim 10^{10}$–10^{12} s for a real waste glass. We therefore suggest that the effects observed with ion beams will not occur in simulated or real glasses in which the damage results from α-decays at a relatively low rate.

Our remarks apply more strongly to the work by Hirsch[12] in which the damage is produced by 2-keV Ar ions. These have a range in the glass of only 2.4 nm and accelerate the damage rate by a factor of perhaps 10^{14}. Such low energy ion beams also produce changes in surface composition and (at high fluences) topography[19–21] which may have more influence on chemical attack than the effects of structural changes produced by radiation damage in the bulk of the material.

Some recovery of damage may also occur during laboratory leach tests if these are carried out at 100 °C as in the Soxhlet method. We estimate that up to 15% recovery could have occurred during leach tests for the samples in Table 1. Obviously recovery effects must be considered both during irradiation and during any tests after irradiation; our estimates show that they could be extremely important in the long time, low dose-rate conditions that apply to real vitrified waste.

McVay and co-workers[13–15] have measured the leach rates of US glass 76–68 while the glass and aqueous leachant were being irradiated with ^{60}Co γ rays at a dose rate of 2.4 Mrad h^{-1}. They found increases by a factor of about two in the rate of loss of weight of the glass and larger increases in the leach rate of some individual elements. They showed that these effects are not due to radiation damage to the glass by γ rays, but must be associated with the effects of radiation on the leachant. In those experiments where air was present, some of the effect could be caused by the production of nitric acid when air or nitrogen is irradiated in the presence of water[22,23]. However, the increases in leach rate in a system in which air was removed[15] must be caused by radiolysis of the water.

To relate these experiments to the conditions likely to exist in a waste repository, we have used the methods of radiation chemistry[24,25] to calculate the concentrations of radicals produced by the irradiation of water next to the glass surface. These calculations consider the known yields[26–27] of the primary species H^+, e^-_{aq}, H, OH, HO_2, H_2 and H_2O_2 produced by ionization of water, and known rates of secondary reactions[28] involving these species, water molecules and possible solutes. We have made preliminary calculations for the following irradiation conditions. (*a*) 2.4 Mrad h^{-1} γ radiation, as used by McVay *et al.* (*b*) 4 Mrad h^{-1} α radiation, which represents the situation for leach rate measurements on samples doped with $^{238}PuO_2$ (see Table 1), where simultaneous leaching and irradiation is inevitable. (*c*) The radiation conditions in a repository, assuming pessimistically that the leachant contacts the glass directly at all times. Some typical dose rates at various times after vitrification are given in Table 2.

Table 2 Typical radiation dose rates to the leachant in a waste repository

Time after vitrification (yr)	Dose rates (Mrad h^{-1}) Lightly ionizing radiation (β, γ)	α radiation
4	5.3×10^{-1}	2.72×10^{-2}
50	8×10^{-2}	2.25×10^{-2}
500	~0	1.08×10^{-2}

These figures assume that the leachant is in contact with the radioactive glass and are based on the same data as in Fig. 1.

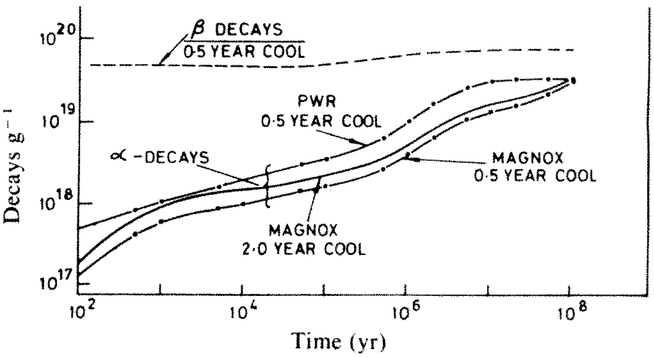

Fig. 1 The number of decays g^{-1} as a function of time for highly active vitrified waste: 12.5% fission products in glass; 0.5% Pu, 0.25% U to highly active vitrified waste. The different curves refer to different reactors and processing conditions as indicated. Each α decay produces over 1,000 atomic displacements whereas each β decay produces ≤ 1 displacement. Long term radiation damage effects are therefore dominated by α decays.

Because dissolved oxygen was removed in McVay and Pederson's experiments[15] and is not expected in an underground repository, most of our calculations are for sealed systems with no gas phase present. However, in case (*b*) we assumed that the water is saturated with dissolved air at the temperature used as was the case in these experiments.

The results are shown graphically in Fig. 2. We note first that in case (*a*) the radicals with highest concentration are OH and O_2^-, suggesting that these are the species responsible for the enhanced leach rates in McVay *et al.*'s experiments (note that McVay and Pederson[15] show that H_2O_2 has no discernible effect). We find small changes (factor of ≤ 2) in the concentrations of H^+ and OH^-. Experiments[29,30] in which leach rate has been measured as a function of *p*H show that such small changes will have a negligible effect on leach rate. The absence of any significant change in initial leach rate for $^{238}PuO_2$-doped glasses when compared with undoped glass (see Table 1) suggests that OH is more active than O_2^- in promoting an increase in leach rate, since we find in Fig. 2 that there is a higher O_2^- concentration in case (*b*) than in case (*a*). Clearly in Fig. 2, in real repository conditions the concentrations of these radicals fall to values low compared with those for the laboratory experiments in case (*a*). We also find that the presence of the solutes NO_3^- and Cl^-, which are found in real waters equilibrated with rocks, can reduce the OH concentration by factors of up to several thousand. We conclude that radiolysis of the leachant will not have a large effect on the leach rate in a real repository.

We have tried to quantify the production of nitric acid when air or nitrogen is irradiated in the presence of water. From experimental data[22,23] we deduce that the nitric acid concentration *N* mol dm^{-3} at time *t* h for irradiation of a sealed air/water system is given by

$$N = 2C_0R[1 - \exp(-1.45 \times 10^{-5}\ GDt)] \qquad (1)$$

where *D* is the dose rate in Mrad h^{-1}, *R* is the ratio of the volume of air to the volume of liquid and the *G* value for the reaction is 1.9. C_0 is the concentration of N_2 in the air in mol dm^{-3}. Equation (1) shows that a *p*H change from 5.7 to 3.3, as observed by McVay and Pederson[15] after 5 days irradiation in the presence of air, would be consistent with a value of *R* of the order unity.

A repository should be free of air pockets soon after burial (N. A. Chapman, personal communication) and the absence of air as a separate phase precludes the formation of nitric acid because this compound is a negligible product of the irradiation of water containing dissolved nitrogen[23,31]. Measurements by Rai *et al.*[32] with particulate suspensions of plutonium compounds suggest that nitric acid could be formed fairly efficiently from dissolved nitrogen, but this interpretation is suspect as air was present in their tubes as a gas, which was probably irradiated by the Pu-containing particles, distributed

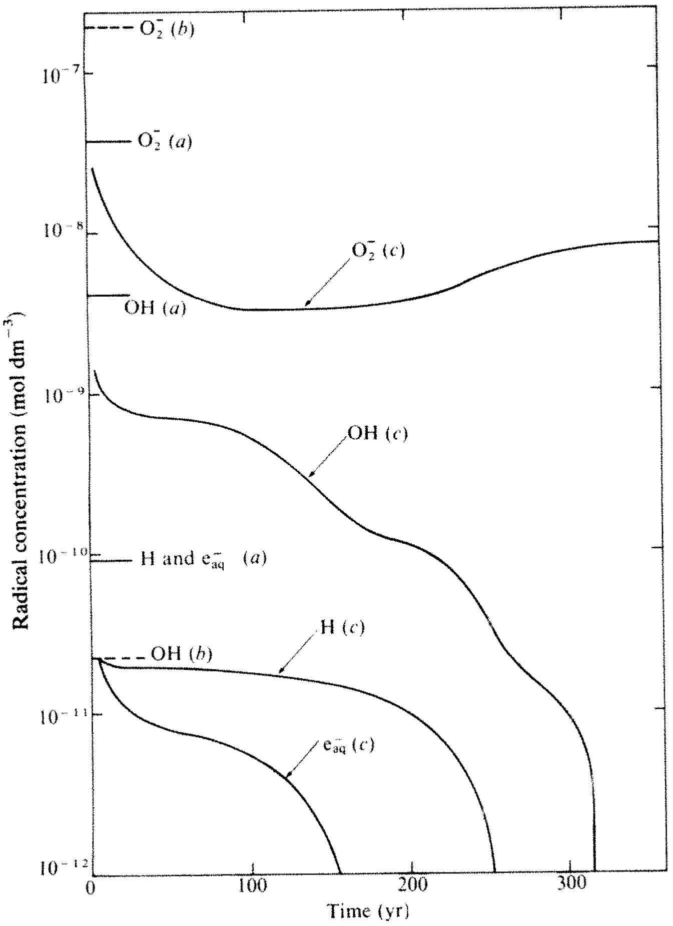

Fig. 2 Concentrations of the radiolytic species H, OH, e_{aq}^- and O_2^- produced by radiolysis of the water next to glass in a repository. The concentrations for irradiation conditions (*a*) and (*b*) described in the text are shown on the left. The H and e_{aq}^- concentrations in case (*b*) are below the scale at 1.1×10^{-13} and 4.1×10^{-14}, respectively. The rise in the O_2^- concentration after ~100 yr is caused by the preponderance of α radiation at long times (see Table 2).

non-uniformly (the greatly increased energy yield found with shaking, and the increase in the rate of acid formation with time support the latter interpretation).

If air were present in a repository the radiation could reach it only through containment and probably a layer of water. At times when the containment may have failed, say after a few hundred years, Table 2 shows that the only significant radiation is from α particles. These have a range of $<4 \times 10^{-2}$ mm in water, so would be completely absorbed in this thickness. The conditions in a repository therefore militate quite strongly against the formation of nitric acid and its consequent contribution to leaching.

The experimental data discussed here all point to leach rates in real repository conditions no more than a few times larger than those of unirradiated glasses. Note, however, that rather wide extrapolations and interpolations in dose rate are involved, and more data are needed over a range of dose rates. Leaching data for specific elements would also be informative because nearly all existing measurements refer to total weight loss. Experiments that have been done suggest that actinide elements dissolve more slowly than the bulk glass structure[14,33].

Note also that the leach rate as usually measured in laboratory tests is unlikely to be the rate-determining factor for the dissolution of glass in a real waste repository, because of the very slow flow rate of water past the glass surface[34-36]. In these conditions the rate of removal of elements from the glass will be controlled by the saturation solubility of the glass in the water, or, in stagnant conditions, by the diffusion of species away from the glass surface[17]. Chapman *et al.*[36] have estimated that the water flow through a (fractured) 1 m^3 block of glass in a repository even without clay backfill would be ~4 ml day^{-1}. If we assume a solubility of 2 g l^{-1}, which is an order of magnitude higher than the solubility of amorphous silica in water at 50 °C (ref. 37), then the rate of mass loss of the block will be 8 mg per day. If the block is fractured into 10-cm cube segments the total surface area is 6×10^5 cm^2 so that the effective leach rate would only be 10^{-8} g cm^{-2} day^{-1}. This can be compared with laboratory values (see Table 1) and the figure of 10^{-7} g cm^{-2} day^{-1} below which radiological analysis gives a clear margin of safety[2]. Backfilling might reduce the flow rate and hence the effective leach rate by a factor[36] of 10^4. A major uncertainty in this argument is the effective solubility of real vitrified waste, but there is evidence that the solubility of actinide species from glasses is extremely low[38]. Radiation damage should not change the solubility by more than a small factor as one is dealing with a situation approaching chemical equilibrium, rather than with a kinetically determined rate process as in a normal surface leach rate measurement.

This work was carried out with the financial support of the Department of the Environment, as part of its radioactive waste management research programme. We thank Drs L. E. J. Roberts, J. Williams, D. Pooley, N. A. Chapman, D. P. Hodgkinson, R. L. F. Kay and Mr D. Savage for valuable comments, and Dr G. L. McVay for discussing his results before publication.

A mesospheric source of nitrous oxide

Edward C. Zipf

Department of Physics and Astronomy, University of Pittsburgh,
Pittsburgh, Pennsylvania 15260, USA

Sheo S. Prasad

Jet Propulsion Laboratory, California Institute of Technology,
4800 Oak Grove Drive, Pasadena, California 91109, USA

In the terrestrial atmosphere, nitrous oxide (N_2O) has a major role in the chemistry of ozone. Current atmospheric models assume that N_2O is produced only by fixation at the Earth's surface and that there are no local sources in the stratosphere or mesosphere. We point out here that a significant *in situ* N_2O source does exist above 20 km due to the excitation of the metastable $N_2(A^3\Sigma_u^+)$ state by resonance absorption of solar UV photons that penetrate deeply into the atmosphere through the λ1,800–2,200 Å O_2–O_3 window. This source significantly affects the NO altitude distribution in the mesosphere and, in the Earth's prebiological atmosphere, made N_2O an important stratospheric constituent.

Literature estimates of the profile of eddy diffusion coefficients, of the effective lifetime of N_2O in the lower atmosphere and of the magnitude of the role of nitrous oxide in the chemistry of the ozone layer are predicated in part on the assumption that there are no significant *in situ* N_2O sources. Previously, the only aeronomically interesting mechanism known to produce nitrous oxide was the reaction[1]

$$O(^1D)+N_2+M \rightarrow N_2O+M \quad (1)$$

But the rate of this reaction in the gas phase is negligibly slow, so that it is not a factor at stratospheric altitudes and above[2]. However, a recent laboratory experiment found that the reaction[3]

$$N_2(A^3\Sigma_u^+)+O_2 \xrightarrow{k_2} N_2O+O \quad (2)$$

produces nitrous oxide with an efficiency of 0.6 ± 30%. Because reaction (2) is the dominant $N_2(A^3\Sigma_u^+)$ loss mechanism below 90 km, the resulting N_2O production rate in the mesosphere and below will be directly proportional to the local $N_2(A^3\Sigma_u^+)$ excitation rate.

Metastable $N_2(A^3\Sigma_u^+)$ molecules are formed efficiently[4] by electron impact

$$e+N_2(X^1\Sigma_g^+) \rightarrow N_2(A^3\Sigma_u^+)+e \quad (3)$$

with a total cross-section that is quite large ($\sim 1.4\times10^{-16}$ cm^2 at 15 eV). In the upper atmosphere, therefore, these energy-rich molecules will be produced copiously by the secondary electrons resulting from the absorption of relativistic electrons and solar protons in the mesosphere[5] and from the absorption of auroral electrons[6] and solar X rays and EUV in the ionospheric D and E regions.

Processes (2) and (3) may result in N_2O concentrations as high as 10^9 cm^{-3} in the auroral D region during an active substorm[6]. However, energetic particle precipitation is a less important $N_2(A^3\Sigma_u^+)$ source mechanism at mid-latitudes and in the equatorial region and at low altitudes ($z < 50$ km). In these regions, optical pumping of the $A^3\Sigma_u^+$ state by the resonant absorption of solar photons in the λ1,800–2,100 Å wavelength range

$$\begin{aligned} h\nu+N_2(X^1\Sigma_g^+) &\rightarrow N_2(A^3\Sigma_u^+) \\ N_2(A^3\Sigma_u^+)+O_2 &\rightarrow N_2O+O \end{aligned} \quad (4)$$

seems to be an effective nitrous oxide source throughout the mesosphere and to altitudes as low as 20 km in the stratosphere.

At first sight, optical pumping of the $N_2(A^3\Sigma_u^+)$ state by solar UV photons looks unpromising: the $A^3\Sigma_u^+$ state is metastable with an average radiative lifetime of 2 s (ref. 7), so that the cross-sections for resonance absorption will be quite small. Furthermore, the Franck–Condon factors for the $X^1\Sigma_g^+ \rightarrow A^3\Sigma_u^+$ transition favour transitions from high vibrations levels ($v''>4$) of the $X^1\Sigma_u^+$ ground state which are negligibly populated at the low temperatures that prevail in the stratosphere. However, from a stratospheric point of view, these properties could be regarded as an advantage because the solar

* For example, 5.04(−18)*R* = $5.04\times10^{-18}\,[J''/(2J''+3)]$ photons per s per molecule.
† For example, 5.04(−18)*P* = $5.04\times10^{-18}\,[(J''+1)/(2J''-1)]$ photons per s per molecule.

0028-0836/82/020133—03$01.00

photons that optically pump the Vegard–Kaplan band system $[X^1\Sigma_g^+ \leftrightarrows A^3\Sigma_u^+]$ will penetrate deeply into the atmosphere before they are absorbed. Thus, the net $N_2(A^3\Sigma_u^+)$ production in the 20–50 km region of the lower atmosphere will reflect the outcome of the competition between process (4) and the absorption of solar photons by O_2 and ozone.

The Vegard–Kaplan bands that contribute most significantly to nitrous oxide production in the mesosphere and stratosphere are the (0, 0), (1, 0), (2, 0), (3, 0) and (4, 0) transitions (see Table 1) which are located quite favourably in the 1,800–2,100 Å $[O_2–O_3]$ atmospheric window.

We have estimated the magnitude of the local $N_2(A^3\Sigma_u^+)$ production rate due to solar UV absorption as follows. The excitation rate of a specific rotational transition (J', J'') for a $(v', 0)$ Vegard–Kaplan band, η, can be expressed in terms of the g-factor[8]

$$\eta(z; v', 0; J', J'') = g(v', 0; J', J'')N_{J''}(z) \qquad (5)$$

where $N_{J''}(z)$ is the population density of the $N_2(X^1\Sigma_g^+)$ ground state molecules in the $v''=0$ vibrational level and in the J'' rotational level at altitude z, and

$$g(v', 0; J', J'') = \pi F_\nu(z)\frac{\pi e^2}{mc} f(v', 0; J', J'') \qquad (6)$$

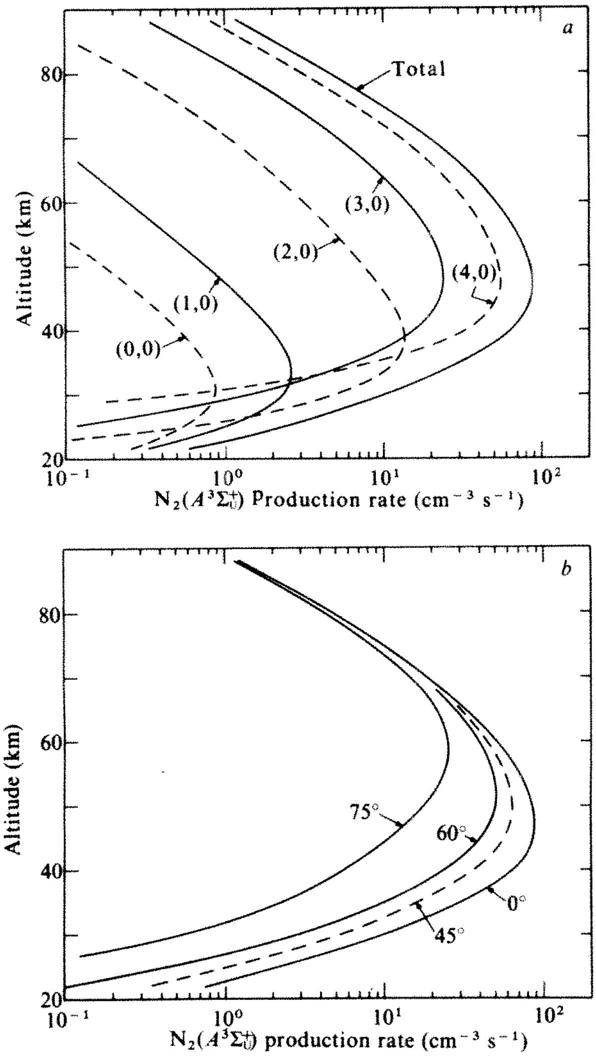

Fig. 2 *a*, Production rates of $N_2(A^3\Sigma_u^+)$ due to solar resonant scattering for overhead Sun conditions. The number in the parentheses denotes the vibrational levels in the $A \leftarrow X$ electron transition. The curve 'total' is obtained by summing the contribution from the various vibrational levels. *b*, Total production rate of $N_2(A^3\Sigma_u^+)$ for various solar zenith angles.

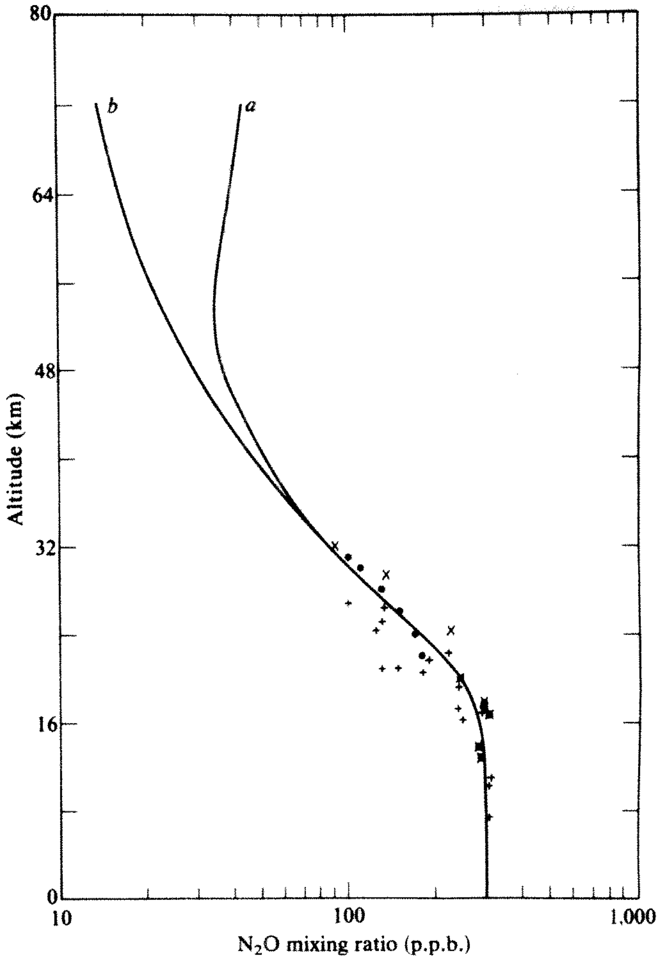

Fig. 3 Mixing ratios of N_2O. Curves *a* and *b* represent theoretical values for two cases: with and without the nitrous oxide production due to the excited $N_2(A^3\Sigma_u^+)$, respectively. Observed values are from Farmer *et al.*[14] (●), Schmeltekopf *et al.*[16] (+) and Ehhalt *et al.*[15] (×).

In this expression, $f(v', 0; J', J'')$ is the optical oscillator strength of the $J'' \rightarrow J'$ rotational transition of the $(v', 0)$ *VK* band, and $\pi F_\nu(z)$ is the incident photon flux at frequency, ν, from the Sun. The local flux can be related to the flux outside the atmosphere, $\pi F_\nu(\infty)$, in units of photons cm^{-2} s^{-1} Hz^{-1} by the expression

$$\pi F_\nu(z) = \pi F_\nu(\infty)\sum_i \exp(-\tau_\nu^i/\mu_0) \qquad (7)$$

where τ_ν^i/μ_0 is the slant optical thickness due to absorption. In this calculation, only O_2 and O_3 were considered as significant absorbers. For modelling purposes, the calculations assumed an effective rotational temperature of 230 K and used the solar flux data published by Nicolet[9].

Values for $f(v', 0; J', J'')$ were derived from the work of Shemansky[7] for the R_2, P_2, Q_1 and Q_3 branches of each of the five *VK* bands $[(v', 0); v' = 0 \rightarrow 4]$ included in this study by using the expression

$$\frac{\pi e^2}{mc} f(v', 0; J', J'') = hc\nu B^{0,v'}_{J'',J'} \qquad (8)$$

The effective optical thickness of the atmosphere due to O_3 absorption was calculated using the cross-section data of Hudson[10] and the ozone profiles given by Nicolet[9]. The effects of O_2 absorption in the Schumann–Runge bands and in the Herzberg continuum were treated in detail. This involved calculating the effective absorption cross-section for each rotational line of the Vegard–Kaplan bands due to the rotational lines of the 14 branches: P_1, P_2, P_3, $^RP_{31}$, $^NP_{13}$, Q_{12}, $^PQ_{23}$, $^RQ_{32}$, $^RQ_{21}$, R_1, R_2, R_3, $^PR_{13}$, $^TR_{31}$. In this computation, the absorption oscillator strengths and line widths given by Lewis *et al.*[11] were used.

Figure 1 shows a representative result for the (5, 0) Schumann–Runge band and the (2, 0) Vegard–Kaplan band. The specific $g(v', 0; J', J'')$ values were then calculated from these results using the solar flux data reviewed by Nicolet[9].

Figure 2*a* shows the production rate for the first five vibrational levels of $A^3\Sigma_u^+$ state due to solar optical pumping for a zenith angle of 0°. At 50 km, the effective N_2O production rate is ~ 51 cm^{-3} s^{-1} assuming a 60% efficiency for reaction (2) (see ref. 3). Based on current one-dimensional photochemical models, the nitrous oxide loss rate due to photodissociation and reactions with $O(^1D)$ atoms would be approximately 79 cm^{-3} s^{-1} and 8 cm^{-3} s^{-1}, respectively, at 50 km. Thus, optical pumping of the $N_2(A^3\Sigma_u^+)$ state by solar UV photons is a significant N_2O source in the mesosphere. Figure 2*b* shows the net $N_2(A^3\Sigma_u^+)$ and N_2O production rates for several solar zenith angles.

To explore the effects of this source, we carried out a globally averaged one-dimensional calculation in which the N_2O photochemistry and transport were treated in detail. The model assumes that N_2O molecules are lost by photodissociation and by reaction with $O(^1D)$ and formed by process (4). The $O(^1D)$ concentration was calculated on the basis of a local chemical equilibrium between its production from O_3 photolysis and loss by quenching collisions with N_2 and O_2. The empirical method of Shimazaki *et al.*[12] was used to determine the absorption of solar UV in the Schumann–Runge bands. We assumed an N_2O mixing ratio of 3×10^{-7} at the lower boundary and a zero flux at the upper boundary at 100 km. Out of the two profiles of eddy diffusion coefficients recommended by Danielson[13], we used the k_1 profile because it gives a better performance in describing the available observations of N_2O. Calculations were done for a solar zenith angle of 30° using the US Standard Atmosphere 1976. Two cases were considered: (*a*) with and (*b*) without the process (4). Results are shown in Fig. 3, together with the observed values of N_2O mixing ratios from Farmer *et al.*[14], Ehhalt *et al.*[15] and Schmeltekopf *et al.*[16]. Because observations of N_2O above 30 km are of low precision they have been omitted. The fact that we reproduce the observed values of N_2O mixing ratios verifies the soundness of our basic model and computational details.

An important point from our analysis is that the new source of N_2O is capable of sustaining significantly increased amounts of N_2O in the upper stratosphere and mesosphere. Compared with the case (*b*), which ignores the process (4), N_2O mixing ratios are increased by 10%, 39%, 102% and 192%, respectively, at 40, 50, 60 and 70 km in the case (*a*). Nitrous oxide is a source of nitric oxide (NO) through the reaction:

$$N_2O + O(^1D) \rightarrow 2NO \qquad (9)$$

Accordingly, increased amounts of N_2O in the upper stratosphere (30–50 km) will lead to increased NO production in this region. In the present calculation, the height-integrated production rate of NO in the 30–50 km region increased by 10%. The observed amounts of NO are less than the predictions of contemporary theories[17] which neglect process (4). Thus, the new source of N_2O (process (4)) magnifies the current discrepancy between the observed and predicted amounts of NO in the upper stratosphere. The key point, however, is that the introduction of this source should lead to a more realistic assessment of this discrepancy and to its satisfactory solution.

Mesospheric NO has been attributed to either the downward transport of NO from the ionospheric E region or to the upward transport from the stratosphere, because there is no *in situ* source of nitric oxide in the mesosphere other than the indirect and weak production by reaction (9). Thus, depending on the transport parameters used, theoretical models had difficulties in accounting for the observed amounts of mesospheric NO (ref. 18), such as those from Tisone's[19] experiments. It is, therefore, significant that the introduction of our new source leads to 100–200% increases in the mesospheric production of NO by reaction (9). Possibly, this increase could alleviate the difficulties of accounting for the observed mesospheric NO.

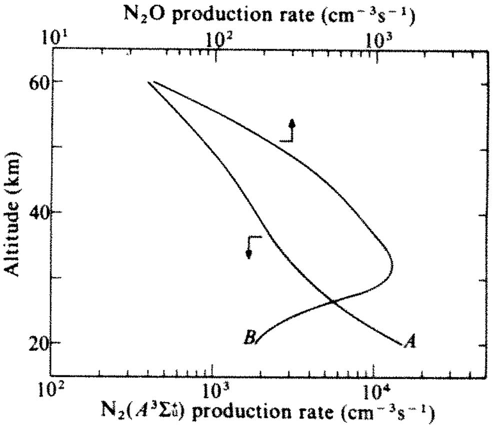

Fig. 4 The $N_2(A^3\Sigma_u^+)$ and N_2O production rate due to solar optical pumping the $A^3\Sigma_u^+$ state 3,500 Myr ago in the Earth's prebiological atmosphere.

Finally, note that the magnitude of the N_2O source due to process (4) is modest in our present-day atmosphere because O_2 and O_3 absorption below 35 km severely attenuates much of the solar flux that would otherwise optically pump the $N_2(A^3\Sigma_u^+)$ state. However, in the Earth's prebiological era ($\sim$3,500 Myr ago), the O_2 and O_3 content of the atmosphere was many orders of magnitude smaller so that copious N_2O production occurred. Figure 4 shows the results of a simplified calculation illustrating the potential magnitude of this source using the prebiological model atmosphere 1 of Kastings and Walker[20].

During this period, the $O(^1D)$ concentration was also very small so that reaction (9) was not a significant N_2O sink; photodissociation and transport were the chief loss mechanisms. In the present-day stratosphere, only solar photons with wavelengths >1,750 Å figure prominently in N_2O photodissociation and result in an effective J_∞ value $\sim 10^{-6}$ s^{-1}. However, with the loss of the O_2–O_3 screening effects in the prebiological atmosphere, more energetic solar photons could reach the upper stratosphere where they would, at first sight, accelerate the N_2O photodissociation. But the absorption by N_2O of most photons with wavelengths $< \lambda$ 1,560 Å leaves the N_2 photofragment in the $B^3\Sigma_g$ or $A^3\Sigma_u^+$ state which subsequently form N_2O through reaction (4), so the effective N_2O photodissociation loss rate at low altitudes is not enhanced much over present-day values. This suggests that the N_2O concentration at 30 km in the Earth's prebiological atmosphere was of the order of 10^9 cm^{-3} during a period well before bacterial action provided a surface source. Ultimately, as the oxygen content of the atmosphere increased, reaction (9) gradually began to provide an atmospheric source of fixed nitrogen (NO) which may have played an important part in the subsequent development of life.

Auroral effects on power transmission line systems

S.-I. Akasofu

Geophysical Institute, University of Alaska, Fairbanks,
903 Koyukuk Avenue North, Fairbanks, Alaska 99701, USA

J. D. Aspnes

Electrical Engineering Department, University of Alaska, Fairbanks,
Alaska 99701, USA

As human activity advances northwards, its supporting systems, such as power transmission lines and oil/gas pipelines, extend across the auroral zone. As the auroral electrojet, a concentrated ionospheric current along the auroral zone, induces a potential of up to 1 V km^{-1} on the Earth's surface, a significant amount of electric current can be induced in long conductors which are grounded at points separated by a long distance[1-6]. We show here that auroral activity can induce surges in the protective relay system of a power transmission line.

We have previously reported that major fluctuations in a power transmission line (138 kV, 100 A) near Fairbanks are mostly induced by auroral activity. The Healy–Fairbanks power transmission line, which runs approximately in the north–south direction (~166 km), is terminated at an autotransformer at the Gold Hill substation which is located just outside the city of Fairbanks. Aurora-induced current fluctuations in the power line were monitored in terms of the autotransformer 'neutral current' by measuring the voltage developed across a 62.5 μΩ resistor inserted between the autotransformer neutral and substation ground.

Figure 1 shows both the 'Earth current' and the neutral current records which were obtained on 3 October 1981. The former was obtained by recording the voltage developed between two electrodes (separated by 100 m) which are located about 5 km from the autotransformer site. Most of the fluctuations in the Earth current were caused by the simultaneous auroral activity[1-7]. Comparing both records, the earth-current fluctuations are well reproduced in the neutral-current fluctuations, indicating that the latter were mostly induced by auroral activity.

To examine possible damaging effects of the aurora-induced currents on the powerline system, however, we need to determine whether such low-frequency (or quasi-d.c.) fluctuations affect the protective relay system and the autotransformer in the circuit. The autotransformer has an electrically isolated winding which provides a current to drive protective relays. This current is zero in a perfectly balanced three-phase power system and is non-zero if an imbalance (such as a short-circuit or other unbalanced load) occurs. An additional cause of increased relay current is an enhancement of certain current harmonics (third, ninth, fifteenth and so on). Half-cycle saturation of transformers caused by d.c. winding current produces such harmonics.

Figure 1 shows the simultaneous record of the current in the protective relay system. The impulsive changes superimposed on continuous and random fluctuations of the neutral current are indicated by arrows. Those impulses were associated with significant low-frequency (or quasi-d.c.) excursions of the neutral current. Figure 2 shows another example of the simultaneous recordings of the current in the protective relay circuit and the neutral current during a medium intensity geomagnetic storm of 19 December 1980. A series of surges can easily be identified in the relay current. We believe that these results are the first confirmation that auroral activity induces surges in the protective relay system of a power transmission line.

D.c. transformer excitation causes a larger than normal amount of harmonic components to be generated in a trans-

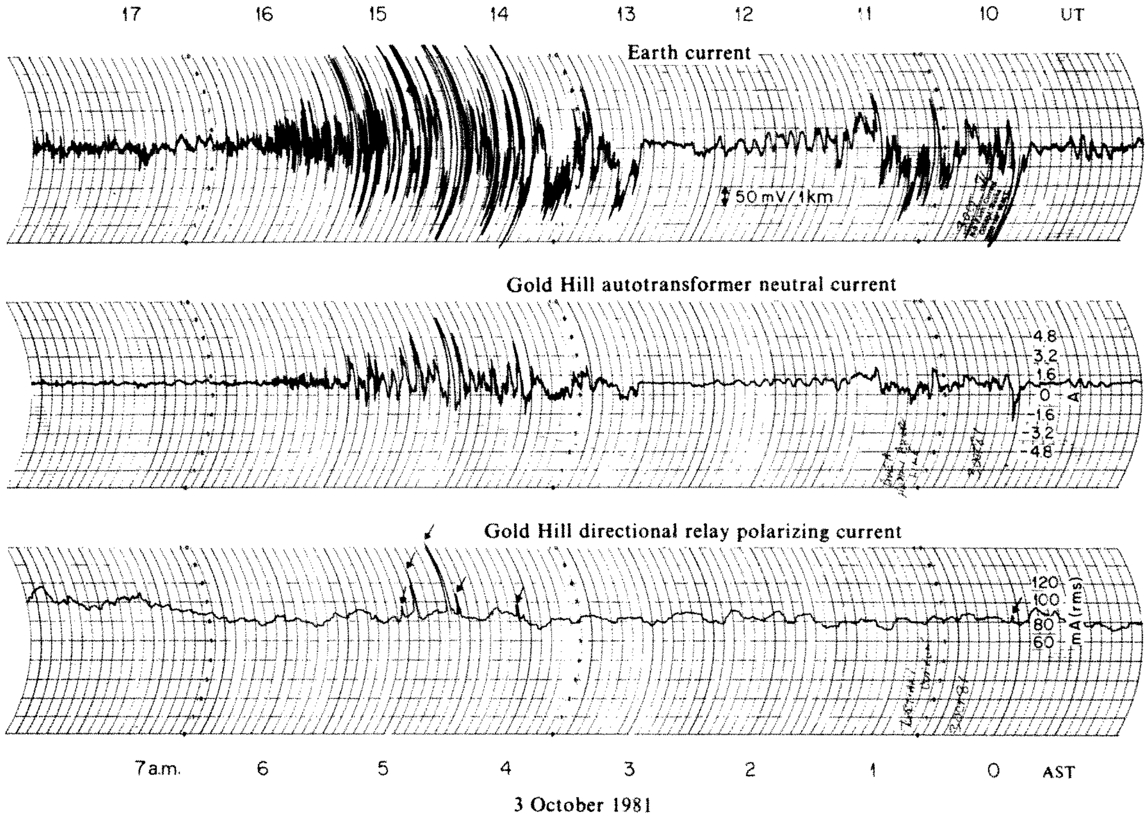

Fig. 1 Simultaneous recordings of Earth current (Earth surface potential), neutral current and protective relay system current (directional relay polarizing current) in the autotransformer located at the Gold Hill substation near Fairbanks on 3 October 1981. Excursions of ±4 A neutral currents represents ±8 A d.c. flowing in the transmission line. AST = Alaska standard time.

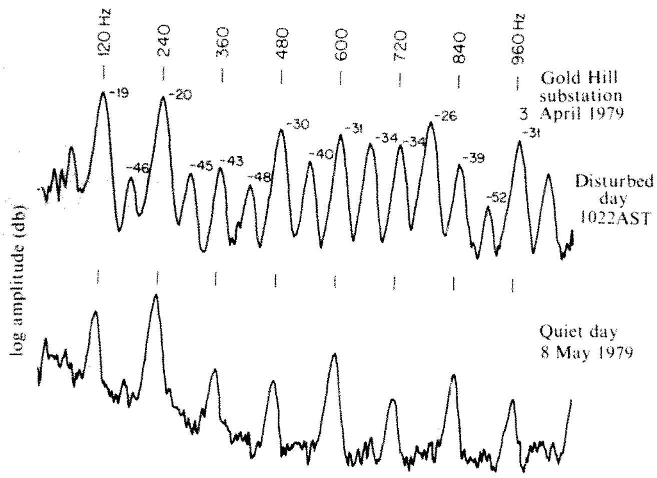

Fig. 3 Transformer sound spectra during a disturbed period (3 April 1979) and a quiet period (8 May 1979).

former[8-10]. Sound spectra were experimentally determined for the autotransformer for periods of both weak and substantial auroral activity at different occasions. This was achieved by a spectrum analyser processing tape-recorded sound measurements. Transformer sound occurs in 60 Hz power systems because ferromagnetic materials change size slightly when magnetized. This change in size (magnetostriction) normally occurs during each half cycle of the 60 Hz fundamental frequency or 120 times s^{-1}. As the magnetostriction process is nonlinear, all harmonics of 120 Hz are also present, contributing to transformer sound output. If d.c. excitation is present, however, the measured transformer sound spectrum contains the 60 Hz fundamental and all harmonics of 60 Hz. This occurs because magnetostriction is no longer symmetrical over successive half cycles of 60 Hz excitation. Figure 3 shows the sound spectrum for a disturbed period and a quiet period, respectively. Note that a large increase of all harmonics of 60 Hz would increase eddy currents in the transformer core and cause possibly destructive transformer overheating.

Acid snow in the Canadian high Arctic

R. M. Koerner & D. Fisher

Polar Continental Shelf Project, Energy, Mines and Resources
Canada, 880 Wellington Street, Ottawa, Ontario,
Canada K1A 0E4

Increasing levels of acid sulphates in precipitation have recently been discovered in locations as far north as Barrow, Alaska and Bear Island (74° N and 19° E) in the Norwegian Sea[1-4]. The high sulphur concentrations are attributed to mid-latitude Eurasian sources[1]. We present here acid concentrations (each representing several years of snow accumulation) in ice from part of a 337-m surface-to-bedrock core on northern Ellesmere Island (81° N, 73° W) representing the past 5,000 yr and compare these with significantly higher acid concentrations in snow deposited over the past 25 yr at the same location showing seasonal variations in the concentrations which together constitute a significant trend of increasing acid levels over the past 25 yr.

Thermal core samples (Fig. 1) were taken in 1977 with a thermal drill at 1,600 m altitude within 1 km of the top of the Agassiz Ice Cap on northern Ellesmere Island, N.W.T., Canada (81° N 73° W). At this location melting occurs in most summers but affects only 3% of the surface annual layer. Samples from these cores were prepared and analysed in our Ottawa laboratory. The ice was first cleaned thoroughly with warm distilled, deionized and filtered water (10 MΩ). The sample was then allowed to melt partially; this melt was discarded. The final melt was collected for analysis and represented <50% of the original sample. The surface samples (Fig. 2) were collected in 1980 with a stainless-steel hand auger and split into two monthly increments. They were then stored in Whirlpak plastic bags that were free from contaminants. The samples were handled with plastic gloves cleaned by 'vigorous rinsing' in clean snow at the site. As these samples were considered uncontaminated for our purposes no cleaning procedures were used. Both core and surface samples were allowed to stand covered to reach room temperature before pH and conductivity (σ) measurements were taken on site. In addition to these samples 400 snow/firn samples were collected from a 10-m pit in 1977 at the same

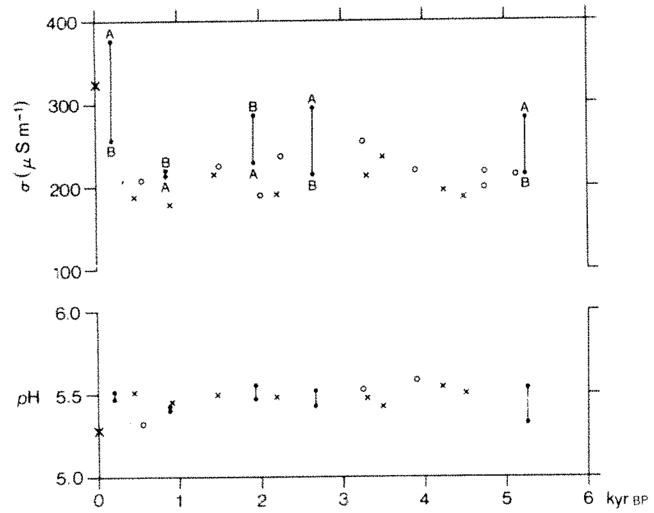

Fig. 1 Electrolytic conductivity (σ, measured with a Radiometer CDM 3m) and acidity (*p*H, measured on an Orion Research Ionanalyser) 0–5,000 yr BP. Agassiz Ice Cap, Canada. A and B represent periods before and after major volcanic eruptions that laid down acid layers on the ice cap. ○, × mean values for samples consisting of five or more years of accumulation. The time scale is based on an analysis of seasonal variations of particulates (measured in a Coulter Counter) and K (measured by graphite furnace AA) at 15 levels in the core.

location. We also measured for Na, Mg, K and Mg using flameless atomic absorption and particulate concentrations.

The reproducibility of the trend of increasing σ with decreasing depth (Table 1) between two sets of samples collected quite differently is strong evidence of the absence of a sampling artefact in the results. However, the most serious 'contaminant' in our samples is CO_2 which appears as H_2CO_3 in our melted samples and increases the acidity. Water at 0 °C (sample just melted) contains about twice as much CO_2 as at the 20 °C at which we measured our samples. We did not ensure complete equilibration with ambient air and therefore some noise from a variable H_2CO_3 background may have affected our results. However, our samples were measured in random order and the trend we discuss later cannot have arisen in this way.

Snow/firn density increases with depth. Therefore, in any one sample the sample-to-air ratio also increases with depth. This lessens the equilibration with air of an enclosed sample with firn depth which, because of lower CO_2 loss from the sample with depth, should increase the acidity in the same direction. Our trend is precisely the opposite and must therefore be reduced by any CO_2 effect.

Our seasonal *p*H cycles agree well in shape and amplitude with the *p*H cycle in snow calculated from sulphate concentration in air over Mould Bay[5] (76° N 120° W). The H^+ noise background due to H_2CO_3 is at most only about a sixth of the magnitude of our seasonal H^+ amplitude and a third of that of the total H^+ change over the past 27 yr and, as we have argued, does not contribute to it. While slightly <70% of the Holocene acid (Fig. 1, Table 1) is calculated to be due to CO_2-associated H^+ ion, the changes above this level, whether they are seasonal cycles or decadal trends, are not due to any variable CO_2 effect.

The Holocene results are shown in Fig. 1 (some results from our investigation of volcanic layers in the ice are included for comparison). The main feature of Fig. 1 is that the present-day (AD 1954–80) acidity ($pH = 5.23$) and σ (311 μS m^{-1}) show the snow is significantly more acid and conductive than snows from the preceding 5,000 yr. Only annual values at the peak of volcanic acid injections into the atmosphere (not shown in Fig. 1) exceed the present-day 25-yr *p*H value. We measured the core samples at our Ottawa laboratory which is some 1,500 m lower in altitude than the field camp where the surface samples were measured. Because of different levels of CO_2 in the air, this makes our Holocene value more acid than the true value (more H_2CO_3 in the sample melt). The 5,000 yr *p*H values for the Agassiz and Devon Island ice caps[6] and Crête, Greenland[7] show a Holocene background value equivalent to ~1.0 μmol non-CO_2 associated H^+ ion kg^{-1}.

The seasonal variation in *p*H and conductivity over the 26-yr period which represents the 'present-day' mean is shown in Fig. 2. The acid and/or conductive peaks are at the surface in May and may be termed a spring peak, although concentrations show an irregular, but overall gradual, increase over the winter. Concentrations of Na, Ca, K, Mg and insoluble particulates are also at maximum in the spring. The ions tend to peak about a month before the insoluble particulates. We do not consider that spring peaking of various elemental constitutents in the snow results from stratospheric injections due to tropopause folding mainly because the particulates increase by a factor of 10 whereas the acid concentration increases by a factor of three. Yet stratospheric chemistry shows a non-volcanic SO_4/Al ratio of 10:1 (ref. 8) (our pre-1963 values cover a volcanically quiet period). As most of the SO_4 ions are present as H_2SO_4 (ref. 8), our spring peak should show a 100-fold and not a 3-fold (4-fold in ref. 5) enhancement of the non-CO_2 associated H^+ ion if we have a 10-fold enhancement of Al (particulates). Over the past 26 yr (where our time scale is based on a knowledge of the surface accumulation rate and the seasonal *p*H and σ variations) the *p*H has shown an overall decrease (Fig. 3 and Table 1) of 0.007 yr^{-1} (or 0.007 μmol H^+ kg^{-1} yr^{-1}). The *p*H and σ trends (3.69 μS m^{-1} yr^{-1}) are compatible with the increase in conductivity being due almost entirely to increasing levels of acid in the snow. If we project this trend backwards we find the acid began to increase from general Holocene values some time in the early 1930s. However, the overall trend may well not be a linear one.

We examine four possible explanations for this trend. First, increasing turbulence in the atmosphere over the past 26 yr might give rise to a longer transport of the H^+ ion without there being any increasing production rate. Second, there may have been decreasing levels of neutralizing components in the atmosphere. Third, there could have been a change in the precipitation or nucleating processes at the cloud level. Finally, we may be seeing a genuine increase in the levels of acid in the atmosphere, generally, or just along a preferred trajectory from a particular source.

Table 1 Particulate, acid, sodium concentrations and electrolytic conductivity of near surface snow and deep ice on Agassiz Ice Cap

Component	Concentration units	Holocene mean	Recent mean pit, 1950–77 (a) core, 1954–80 (b)	Recent trend per yr pit, 1950–77 (a) core, 1954–80 (b)
Particulates $d > 1.0\mu m$	No. × 10^3 l^{-1}	18.2	18.3 (a)	0.6 (a)
Na	p.p.b.	32*	25 (a)	0.47 (a)
Electrical conductivity	μS m^{-1}	201	314 (a) 311 (b)	3.3 (a) 3.7 (b)
Acid	*p*H	5.48	5.28 (a) 5.23 (b)	— −0.007 (b)

* All associated with volcanic episodes.

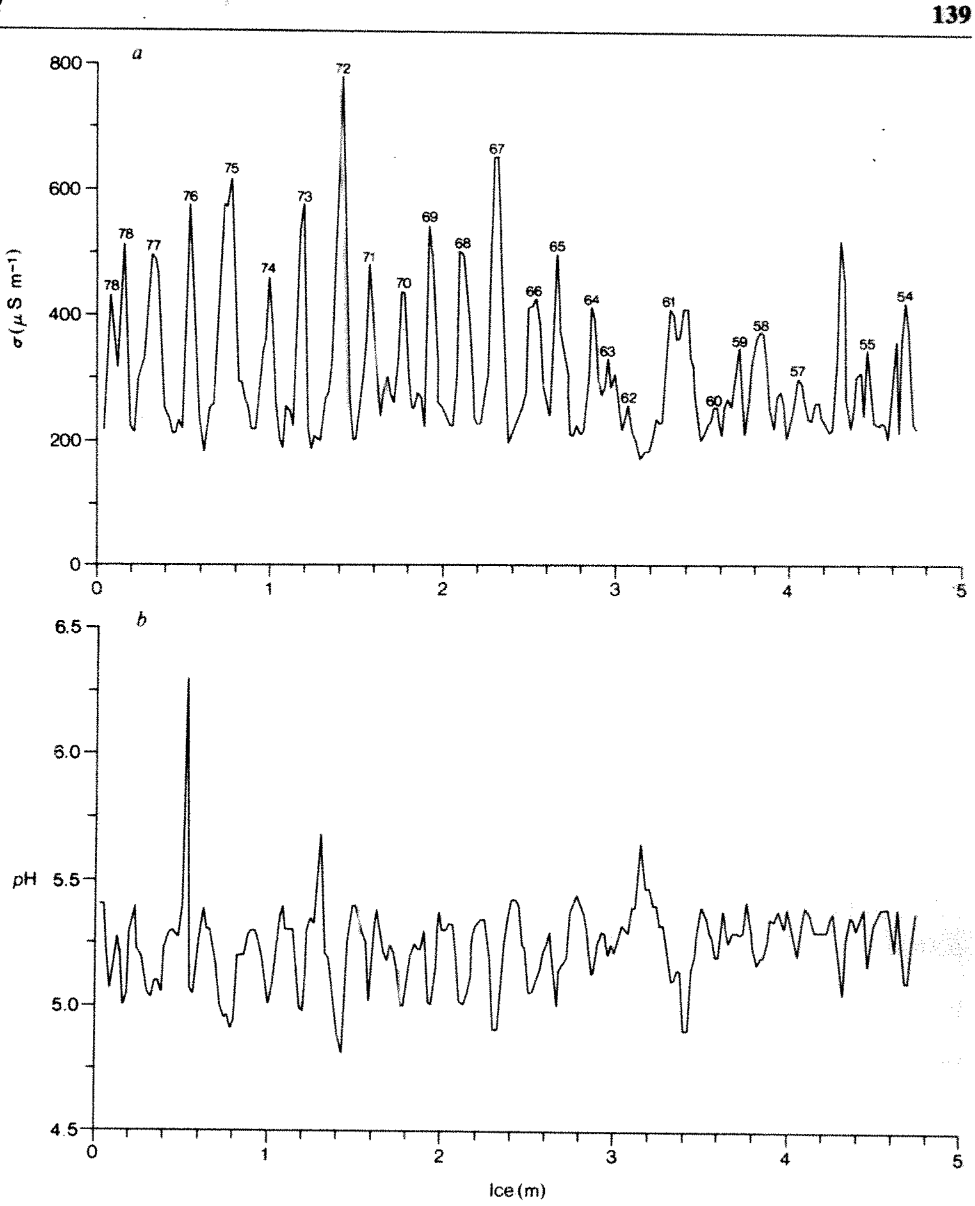

Fig. 2 Seasonal variations of *a*, electrolytic conductivity (σ), and *b*, acidity (*p*H) as measured on a 10 m core from Agassiz Ice Cap, Canada. The numbers refer to the spring in each year according to 72 = 1972.

From our pit results in 1977 we find significant trends of increasing concentrations of sodium and particulate matter in the snow (Table 1). At first sight this could be seen as evidence of increasing turbulence in the high Arctic over the same period. However, present-day particle concentrations (Table 1) are not significantly different to those over the past 5,000 yr. The same is true of our Devon Island core[6] and also of the Crête core in Greenland[7]. This indicates that there have been no major changes in turbulence at the ice cap site or in the high Arctic generally over the same period. The lack of change in particulate concentrations would also suggest that there has been little general change in the neutralizing capacity of aerosols over the high Arctic in the past 5,000 yr.

Junge[9] cautioned against considering that changes in concentrations of elemental components in ice cores represent or are the effect of similar changes in aerosol composition and concentration. He believes changes in the moisture content of precipitating clouds (c) and/or the mass fraction of aerosols used for condensation (ε_m) would cause changes in the concentration of the same aerosols when incorporated in the snow. However, we do not find a significant correlation between the changing acid concentrations and $\delta^{18}O$ in the snow. The $\delta^{18}O$ value is largely determined by the temperature of condensation at the cloud level[10] and temperature at this level is probably the main determinant of c and possibly ε_m.

We are, therefore, left with the most likely explanation that increasing acid levels in the snow are due to similarly increasing acid levels in the atmosphere over the ice cap and that this mutual increase is somehow allied to augmented acid production at its source. The source(s) could be natural (volcanic) or anthropogenic (industrial pollutants). There have not been steadily-increasing levels of volcanic sulphur injections into the atmosphere over the past two decades[11,12] which does not favour a volcanic acid origin. Stratospheric SO_4 concentrations measured in quiet, that is non-volcanic, periods have been increasing by 9% yr^{-1} over the past 20 yr (refs 11, 12). The increase has been assigned an anthropogenic origin[11,12].

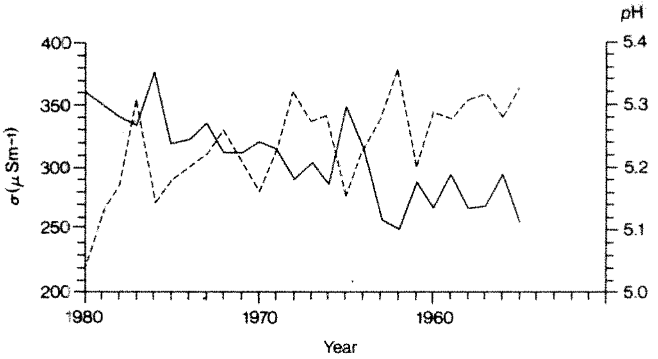

Fig. 3 Annual values (measured from spring to spring) of acidity (*p*H, dashed line) and electrolytic conductivity (σ, solid line) from a 10-m core on Agassiz Ice Cap, Canada.

However, because we do not detect the eruption of the volcano Gonung Agung in 1963 in our work (Fig. 2), we must be measuring a tropospheric acid input to the northern Ellesmere ice cap rather than a stratospheric one (which agrees with our earlier comments on the spring maximum of dust, acid and other ions). In the same tropospheric context high levels of industrial sulphates have already been shown for Barrow, Alaska[1,2,4] Bear Island[3] in the Norwegian Sea and Mould Bay in Arctic Canada[5]. Increases in sulphates have also been declared for Greenland over the past 20 or 30 yr (refs13, 14) and for post-1970 snows compared with pre-1900 snow[15]. However, in recent work there is no evidence for a trend of increasing acid levels in the snow at Crête, Greenland[7]. Similarly, detailed electrolytic conductivity measurements made at the top of the Devon Island ice cap (1,800 m a.s.l.) and spanning more than 30 yr show no conductivity trend between 1942 and 1972. The lack of increasing conductivity in recent snows on the Devon Island Ice Cap, although the present-day value there is significantly higher than the Holocene one, may be due to the fact that the Devon Island Ice Cap has a very strong input of marine aerosols[6] which presents a strong noise background that is swamping the acid trend. However, we cannot ignore the possibility that the proposed acid trajectory across the Arctic Ocean from Eurasian sources[1,2,4] excludes those high Arctic areas distant from the Arctic Ocean thereby favouring northern Ellesmere rather than Devon Island or Crête, Greenland. We should mention that preliminary results from a hand-cored profile at 82° N 77° W also on northern Ellesmere but closer to the Arctic Ocean than the Agassiz Ice Cap show an identical trend to the latter's of increasing acidity over the past 28 yr.

The full implications of increasing acid precipitation in the High Arctic are beyond the scope of this paper. However, the most acid snow is at the snow surface when melt begins in May or June in the high Arctic. Unless this melt refreezes at the base of the snowpack, the first runoff in spring will be the most acid. Acid levels in high Arctic snow, and their effects, should therefore be monitored on a routine basis as in certain areas, for example where lake fish form a source of Inuit income, there could be social implications.

Molluscan biostratigraphy of the Koobi Fora hominid-bearing deposits

Peter G. Williamson

Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138, USA

Since the discovery[1] of late Cenozoic hominid-bearing deposits in the Koobi Fora area, north Kenya, a variety of studies[2–9] have been undertaken to provide a chronostratigraphical and palaeoenvironmental context for the important palaeoanthropological and early archaeological discoveries[1,10]. Unfortunately, although the exposures are areally extensive (>1,000 km^2), they are broken up into subareas (Fig. 2); these local sections are often difficult to correlate with one another due to intervening bush cover and faulting. Here I summarize a molluscan biostratigraphical analysis which demonstrates serious stratigraphical miscorrelations between certain local sections, including some previously indicated by vertebrate evidence. These miscorrelations require substantial revisions to current stratigraphical interpretation of the Koobi Fora deposits. In particular, both the Suregei and Tulu Bor tuff horizons actually represent different levels. Although the Tulu Bor is considered to overlie the Suregei, some exposures currently attributed to the Tulu Bor are actually older than some units previously mapped as the Suregei. Fortunately, the stratigraphical miscorrelations reported here do not significantly affect the relative placement of the mollusc faunas reported in a previous evolutionary analysis[15]; superpositional relationships in the areas from which these faunas were collected (mainly collecting areas 102, 103, 110, 123, 202 and 203) are unaffected by the miscorrelations reported here.

Lithostratigraphical correlations in the Koobi Fora area have been based on certain tuffaceous horizons which regularly punctuate the late Cenozoic sequence. These tuffs are generally secondarily waterlain[5,6]; their bases have been considered laterally extensive, mappable and essentially isochronous[11,12]. The supposed recognition of these tuffs in geographically-separated local sections has formed the basis of a regional chronostratigraphical scheme[5–7] (Fig. 1*a*); this scheme has provided a framework for palaeontological discoveries and palaeoenvironmental interpretations. The validity of this framework, and of all interpretations based on it, relies entirely on the correct recognition and correlation of the various tuffs in widely separated local sections. But these tuffs are laterally variable in field aspect, and proposed correlations between local sections are therefore often questionable. In addition, vertebrate studies have suggested miscorrelations between certain tuffs[13,14].

Fig. 1 Stratigraphical relationships of late Cenozoic deposits of the Koobi Fora region. A, Currently accepted stratigraphical framework (after ref. 7). B, Generalized revisions suggested by this report. Note that several tuffs previously allocated to the Suregei and Tulu Bor Tuffs actually represent horizons of widely differing age. These various horizons are designated by the informal terms 'Tulu Bor '1'', 'Tulu Bor '2'', and so on. This terminology, adopted here solely to indicate which horizons were previously considered lateral correlates, has no formal status whatsoever. The different Tuff horizons previously allocated to the Suregei and Tulu Bor Tuff levels are also distinguished by the 'area/succession' scheme suggested by Harris and White[13]; a given tuff exposure is designated by the collecting area in which it occurs, and by its stratigraphical position with respect to other tuffs within the local section of that collecting area. Thus, the designation 102/TI indicates the earliest (lowest) tuff in the local stratigraphical sequence in collecting area 102. Total thickness of the Kubi Algi, Koobi Fora and Guomde Formations is considered to be ~350 m (ref. 7).

0028–0836/82/020140—03$01.00

The profound evolutionary changes recorded in the mollusc faunas of the Koobi Fora area[15] permit the recognition of several events which are time-significant for the basin. Putative correlations between exposures of marker tuffs in various areas were therefore tested using these faunas. Molluscan biostratigraphical type sections were designated in the same general areas as the lithostratigraphical type sections for the three late Cenozoic formations of the area, and on the basis of the evolutionary events recorded in 40 mollusc faunas from these type sections, 10 concurrent range zones were defined (Fig. 3); 112 faunas collected in other areas, away from the type sections, were then allocated to the appropriate biozone. When these latter faunas occur close to local exposures of the various marker tuffs, the position of these tuff exposures relative to the molluscan type section can be more or less accurately determined.

Although the biostratigraphical type sections for each of the three late Cenozoic formations in the area are continuous local sections, these sections are, like the lithostratigraphical type sections, geographically separated (Fig. 2). However, the superpositional relationships of these sections are unambiguous[16]. Together, these three sections exhibit 9 of the 10 proposed molluscan biozones (zones 2–10). Zone 1 is not certainly developed in the lithostratigraphic type section of the area; the type section for this zone is the Karsa Waterhole sequence[17], which appears either immediately to predate the Kubi Algi Formation, or to correspond to some level in the lower half of this unit (I.C. Findlater, personal communication) (no mollusc faunas are known from the lower half of the type section of the Kubi Algi).

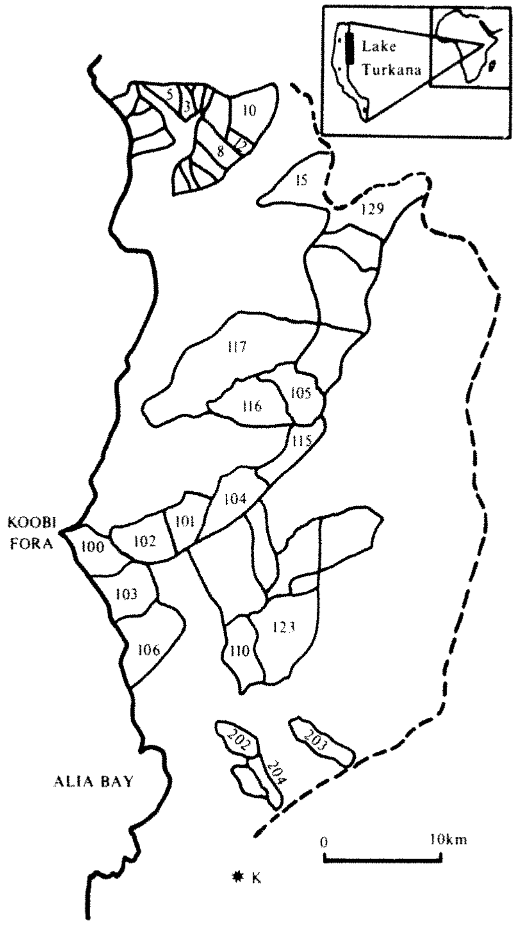

Fig. 2 Principal palaeontological collecting areas designated in the Koobi Fora area, north Kenya. Molluscan biostratigraphical type section for the Kubi Algi Formation is in area 203, that for the Koobi Fora Formation in area 102, and that for the Guomde Formation in area 3. These type sections encompass molluscan biozones 2–10; the type section for zone 1 is the Karsa Waterhole sequence[17] ('K'), to the south of the basin margin (indicated by heavy broken line).

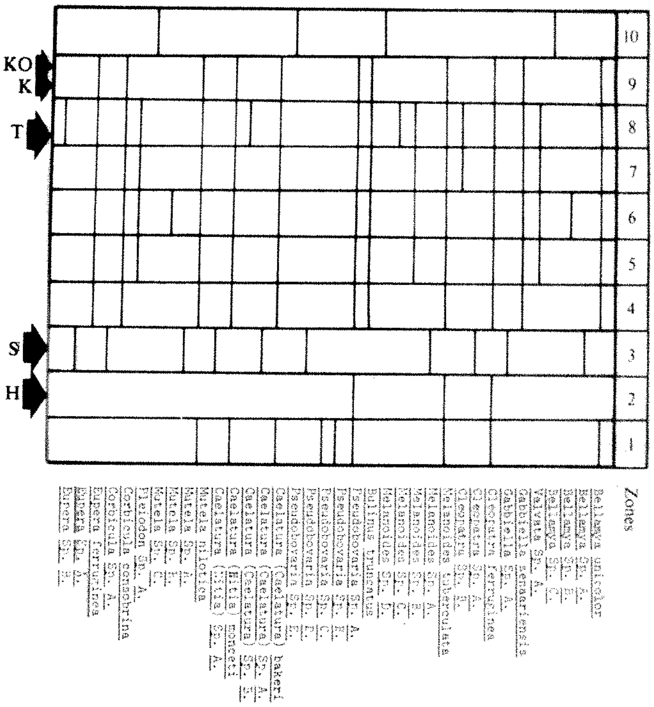

Fig. 3 Range zones of freshwater molluscs from the Plio–Pleistocene deposits of the Koobi Fora area. Zone 1 faunas are characterized by the presence of two distinctive forms of *Pseudobovaria* and by the absence of *Corbicula*. Zone 2 faunas consist of widely distributed and generally still extent taxa, but are taxonomically restricted and dwarfed, reflecting the period of high alkalinity consequent on the marked regressive phase at and above the Hasuma Tuff level[7]. Zone 3 faunas document contemporaneous speciation events in all lineages in the basin during a continuation of this regressive phase, and presumed geographical isolation of faunas[15]. Zone 4 faunas document the elimination of the zone 3 endemics as typical ancestral stocks return to the basin, coincident with a major transgressive phase. Zones 5–8 document a progressive intrabasinal radiation of several of these stocks and the accumulation of certain 'exotic' taxa in the Lower Member of the Koobi Fora Formation. Zone 9 documents a major reduction in faunal diversity; all the endemics and exotics of zones 5–8 were extirpated by the rise in alkalinity[24] in the uppermost Lower Member consequent on a climatically induced[25] regression[6,26]. The zone 10 faunas from the Guomde Formation document a second series of contemporaneous speciation events in the various lineages present in the basin, again coincident with major regression and presumed geographical isolation. Widths of zones as drawn do not reflect their relative stratigraphical thicknesses. Heavy arrows to side of diagram reflect the placement of certain tuff horizons with respect to the molluscan biozones, in the biostratigraphical type section. H, Hasuma Tuff; S, Suregei Tuff; T, Tulu Bor Tuff; K, KBS Tuff; KO, Koobi Fora Tuff.

The evolutionary events previously documented[15] in the mollusc faunas of the Koobi Fora region actually form the basis for the differentiation of zones 2–10 inclusive. The faunas here attributed to zone 1 have not been reported previously; they are characterized by the presence of two distinctive species of *Pseudobovaria* and by the absence of the now extremely widespread and eurytopic genus *Corbicula*. One or other of these forms of *Pseudobovaria* have been previously recognized by Vandamme from either the Kanapoi deposits to the south of the Turkana Basin, or from the lower parts of the Omo Valley sequence to the north[18]. Both forms of *Pseudobovaria* apparently became extinct during the high alkalinity phase documented by the stunted zone 2 faunas; *Corbicula* appears to have been a rather recent Eurasian immigrant into Africa[19]. Zone 1 faunas are also now known from the Warata Formation[20], north-east of the Koobi Fora area.

The stratigraphical positions of various marker tuff horizons relative to the biostratigraphical type section can be determined when the mollusc faunas bracketing them are allocated to the proposed biozones. Clearly, the precision with which a tuff horizon in a given local section can be related to the biostratigraphical type section will be determined by how closely it is bracketed by zonally attributable mollusc faunas. The relative

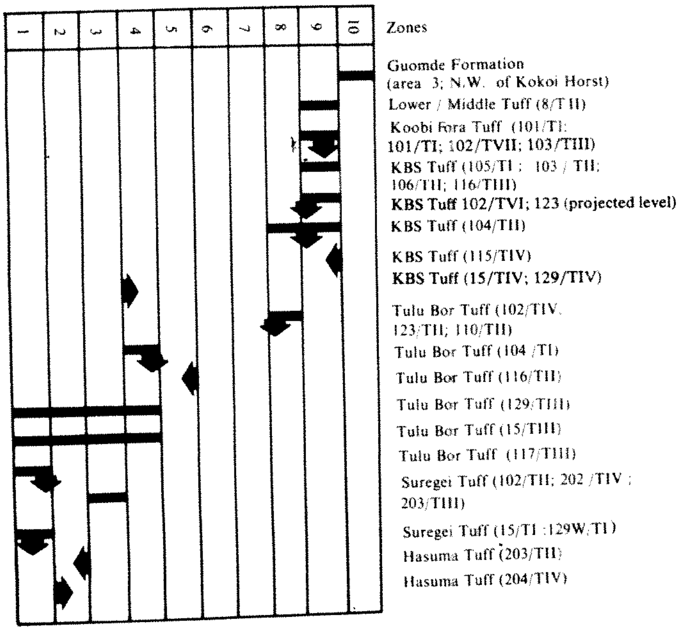

Fig. 4 Positions of various exposures of the major marker tuffs, and of Guomde age sediments, with respect to the various molluscan biozones. Possible range of positions of the tuffs within the zonal scheme indicated by heavy vertical bars. Most probably positions of the various tuffs, suggested by superpositional data and by propinquity to zone boundaries, indicated by horizontal arrows. Upward and downward facing arrows indicate the uppermost and lowermost possible positions, respectively, of poorly bracketed tuffs. Note that horizons attributed to both the Tulu Bor and Suregei levels fall into a wide range of biozones, suggesting the stratigraphical revisions indicated in Fig. 1*b*. Notations after tuff names indicate the geographical and stratigraphical positions of the various tuff horizons according to the scheme suggested by Harris and White[13]; a given tuff exposure is designated by the collecting area in which it occurs, and by its stratigraphical position with respect to other tuffs within the local section of that collecting area. Thus, the designation 102/TI indicates the earliest tuff in the local stratigraphic sequence in collecting area 102. Allocation of the horizon attributed to the Suregei Tuff in areas 15 and 129 to zone 1 assumes the apparently firm short-distance lithostratigraphical correlation between these areas to be correct (this horizon is immediately underlain by zone 1 faunas in area 15, and immediately overlain by zone 1 faunas in area 129).

positions of several important exposures of marker tuffs, determined as accurately as possible by this method, are indicated in Fig. 4. Several serious miscorrelations of tuffs have occurred. In particular, various horizons allocated to the important Suregei and Tulu Bor Tuffs fall, in both cases, into different biozones; both stratigraphical terms therefore encompass several horizons of differing age. (Studies on fossil suids from these deposits have previously suggested that certain exposures assigned to the Tulu Bor Tuff in fact pre-date the Suregei Tuff horizon of the type section of the Koobi Fora and Kubi Algi Formations[13,14]. A generalized and tentative revised stratigraphy suggested by this analysis is indicated in Fig. 1*b*. Only tuffs whose relative positions with respect to the biostratigraphical type section are unambivalent are indicated; the remaining, less securely bracketed tuffs shown in Fig. 4 may or may not be lateral correlates of those shown in Fig. 1*b*. In addition, due to the absence of faunal evidence from the Alia Tuff, its stratigraphical position with respect to the 'Tulu Bor 3' and 'Suregei 2' horizons (see Fig. 1) is unclear.

The present study has three immediate implications:

(1) The Plio–Pleistocene deposits of the Koobi Fora area were originally divided by Bowen and Vondra[21] into two main stratigraphical units, the Kubi Algi and overlying Koobi Fora Formations and the boundary between them was formally defined as the base of the Suregei Tuff[21]. The type locality of the Suregei Tuff lies close to the Suregei escarpment (from which it is named) in area 15 (refs 13, 14) (see Fig. 2). Unfortunately, as demonstrated above (Fig. 4), this tuff exposure is substantially older than its supposed correlate horizon in areas 102, 202 and 203 (Koobi Fora–Alia Bay area). But this latter horizon lies within the formal type sections of both the Kubi Algi and Koobi Fora Formations! Clearly, the terms 'Kubi Algi Formation', 'Koobi Fora Formation' and 'Suregei Tuff' must be either redefined or abandoned.

(2) In terms of the currently accepted stratigraphical scheme, large areas of exposure in areas 117, 129 and 15, previously allocated to the Koobi Fora Formation, are considerably older than the lithostratigraphical type section of this unit, and apparently correspond in age to some part of the type section of the Kubi Algi (see also refs 13, 14).

(3) Hitherto, the apparent restriction of Kubi Algi age sedimentation to the southern part of the Koobi Fora region (Alia Bay area) implied a generally regressive regime in the earlier Plio–Pleistocene[7], succeeded by a major transgression at the (apparently) areally extensive Suregei Tuff level[7]. In contrast, the Mursi, Usno and Lower Shungura Formations in the neighbouring Omo area document intermittently widespread lacustrine conditions throughout this period[22,23]. However, recognition that Kubi Algi age sedimentation occurs throughout the Koobi Fora area, and that the 'Suregei Tuff' level consists of at least two separate horizons and does not represent one extensive depositional event during a single major transgression, implies a similar picture of intermittent lacustrine conditions in the earlier Plio–Pleistocene throughout the Koobi Fora region. These observations bring the depositional histories of these two regions into greater congruence, suggesting that widespread lacustrine conditions pertained intermittently throughout the Turkana Basin in the earlier part of the Plio–Pleistocene depositional cycle.

Aneural muscle cell cultures make synaptic basal lamina components

Laura Silberstein, Nibaldo C. Inestrosa*
& Zach W. Hall

Division of Neurobiology, Department of Physiology, University of California, San Francisco, San Francisco, California 94143, USA

The basal lamina that runs between the presynaptic and postsynaptic membranes at the neuromuscular junction has distinctive functional properties[1-3] amd differs in molecular composition from the extrasynaptic basal lamina to which it is attached[4,5]. In regenerating muscle, synaptic basal lamina can direct the accumulation both of neuronal transmitter vesicles at specific sites near the presynaptic nerve terminal membrane and of acetylcholine receptors (AChRs) in the postsynaptic muscle membrane[1-3]. Four components that are concentrated in synaptic basal lamina, but are not detectable in extrasynaptic basal lamina, have been recognized. The first is a particular form of acetylcholinesterase (AChE), the A_{12} or 16S species, which is concentrated at the synapse in rats[6,7] and mice[8]; its distinctive feature is thought to be a long collagen-like tail[9] that attaches it to the basal lamina[10]. Three other components of the synaptic basal lamina have been distinguished immunocytochemically using antisera raised against basement membrane extracts or collagen-rich preparations[4]. Although it has been previously reported that aneural muscle cell cultures may make the 16S form of AChE[11,12], the role of the nerve in the synthesis and organization of the synaptic basal lamina is unknown. We report here that cells of a mouse muscle line, in the absence of nerves, have surface accumulations of each of the four synaptic basal lamina components described above: the 16S AChE, and cross-reactive antigens recognized by each of the synapse-specific antisera.

Cells of the C_2 line, derived from regenerating skeletal muscle of adult C3H mice[13], proliferate as myoblasts in high serum medium (Dulbecco's minimal essential (DME) medium containing 0.5% chick embryo extract and 20% fetal calf serum) and fuse into myotubes in low serum medium (DME with 10% horse serum). Within 3 days after the medium is changed, the cultures contain numerous long, cylindrical, multi-nucleated myotubes that contract spontaneously. The synapse-specific basal lamina antigens were detected using three sera described by Sanes and Hall[4]: we refer to the serum produced against solubilized anterior lens capsule as 'junctional-specific I' (JS-I); to the serum raised against muscle basement membrane collagen, and subsequently adsorbed with extrasynaptic muscle basement membrane so as to reveal synapse-specific antigens, as JS-II; and to the serum produced against lens capsule collagen and similarly adsorbed, as JS-III. Some experiments were also performed with the unadsorbed sera, which stain both synaptic and extrasynaptic basal lamina. Immunofluorescence observations were made as described by Sanes and Hall[4]. Methods for detection of AChE are described in detail elsewhere[8,14,15].

C_2 myotubes, cultured without nerve cells, synthesized the synapse-specific A_{12} form of AChE. After 5 days in fusion medium, ~30% of the total AChE activity sedimented at 16S (Fig. 1*a*). Histochemical examination of these fibres showed a patchy distribution of enzyme activity on the myotube surface (Fig. 1*b*). Such focal accumulations of AChE have been observed by others in primary myotube cultures from rat or chick embryonic myoblasts only in the presence of nerves[12,16-18]. Focal accumulations of AChE in such nerve–muscle co-cultures appeared at the same time as the A_{12} form of the enzyme[12,18]. We have demonstrated, and report in detail elsewhere, that the patches of AChE observed in aneural C_2 cultures correspond to the A_{12} form of enzyme and are apparently associated with the extracellular matrix[8,19].

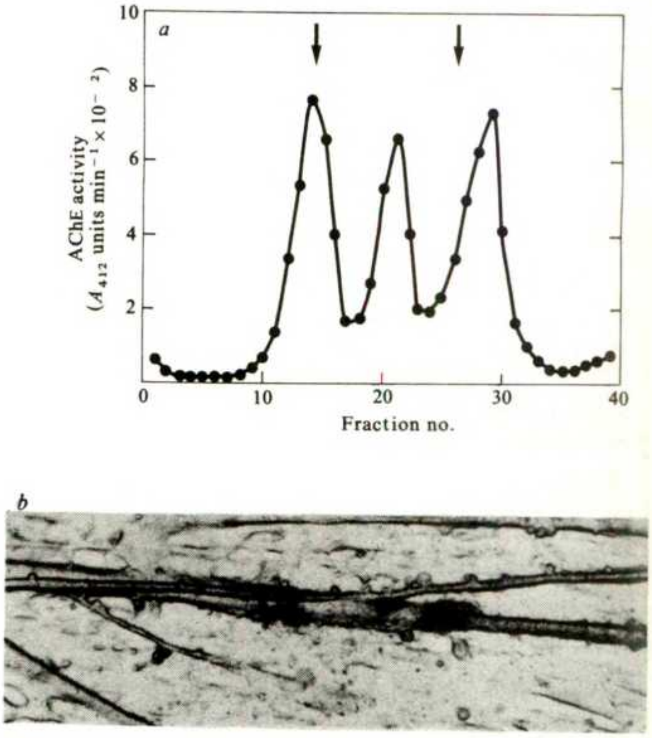

Fig. 1 Molecular forms and focal accumulations of AChE in C_2 myotube cultures. C_2 myotubes were grown for 5 days in fusion medium on a tissue culture plastic substrate and then examined for esterase activity. *a*, AChE was extracted from myotubes in a high ionic strength (1 M NaCl) buffer containing 0.5% Triton X-100, 20 mM EDTA and protease inhibitors[8], and analysed by zone sedimentation on a sucrose gradient[6]. Enzyme activity was measured by the Ellman procedure[14]. The arrows indicate the position of (left) β-galactosidase (16S) and (right) alkaline phosphatase (6.1S). *b*, Esterase activity was localized *in situ* using the histochemical method of Karnovsky and Roots[15] following fixation with 1% paraformaldehyde and 0.8% glutaraldehyde in 0.13 M sucrose buffered with 90 mM sodium phosphate, *p*H 7.4 (ref. 17). ×335.

To visualize the extracellular matrix produced by C_2 myotubes, we used antisera that bind uniformly to synaptic and extrasynaptic basal lamina in rat muscle[4] and mouse muscle (L.S. and Z.W.H., unpublished) (see Fig. 2*a*). The matrix formed a network of fibrils that stretched from cell to cell connecting the unfused myoblasts and myotubes, while an uneven pattern of staining outlined each myotube. Antibodies bound at low density over large areas of the myotube surface; more intense staining was seen in small patches and in long, thin arcs. None of these patterns was observed in control cultures that had been incubated with non-immune serum. These results show that the C_2 cells produce an extensive extracellular matrix.

We observed a more restricted distribution of immunofluorescence following incubation of the cultures with the synapse-specific antisera. In most cases, the antigens appeared as either arcs (Fig. 2*c*) or patches (Fig. 2*b,d*) on the myotube surface. Myotubes stained with the JS-III serum often displayed areas of fluorescent speckles (see Fig. 2*d*), a pattern not seen with the other synapse-specific antisera. Adsorption of each of the synapse-specific sera with C_2 myotubes abolished the staining of endplates in frozen sections of mouse muscle. Thus, the antibodies bound by C_2 myotubes are those recognized by the adult muscle synaptic basal lamina.

The arcs and small patches resembled the distribution of clusters of AChRs seen in separate experiments. Simultaneous labelling of the receptors with rhodamine-conjugated α-bungarotoxin and of the antigens with fluorescein-conjugated

antibody demonstrated that in many cases the antigens were restricted to areas of the myotube surface containing high concentrations of AChRs. As shown in Fig. 3, the coincidence of the two was often striking. The greatest coincidence of antigens with AChR clusters was observed with the JS-I serum. In cultures examined 3 days after fusion, 30–45% of all receptor clusters coincided with patches of JS-I antigen(s). Similarly, the JS-II antigen(s) sometimes appeared in patches whose distribution was identical to that of AChR clusters. In both cases, however, antigen patches unrelated to receptor clusters were also present. Co-localization of the JS-III antigen(s) with AChR clusters has thus far not been observed in C_2 myotube cultures. Because at least one synaptic basal lamina component, JS-III, seems to be unrelated to receptor clusters whereas the other two sometimes are, the distributions of each of the synaptic basal lamina antigens cannot be completely coincident.

The presence of synaptic basal lamina components in aneural C_2 myotube cultures can perhaps be understood in the context of myoblast maturation. Several studies suggest that the myoblast's potential for gene expression changes through a maturation sequence that is dependent on innervation. For example, Koenig and Vigny[12] observed that myotubes in primary rat muscle cultures could make 16S AChE in the absence of nerves only if derived from embryonic muscles that had already been innervated; myotubes formed by cells from uninnervated muscles could make 16S AChE only if co-cultured with nerves. Similarly, in chick muscle, both the ability of myoblasts to fuse *in vitro* and the morphology of myotubes seem to be regulated by neural contact within the limb bud[20–25]. The ability of C_2 myotubes to express 16S AChE, as well as other synapse-specific components of the basal lamina, is consistent with this scheme, as the cell line is derived from adult muscle; that is, the C_2 cell line may represent an advanced stage of myoblast differentiation that results from *in vivo* exposure to neuronal influences before isolation of the myoblasts.

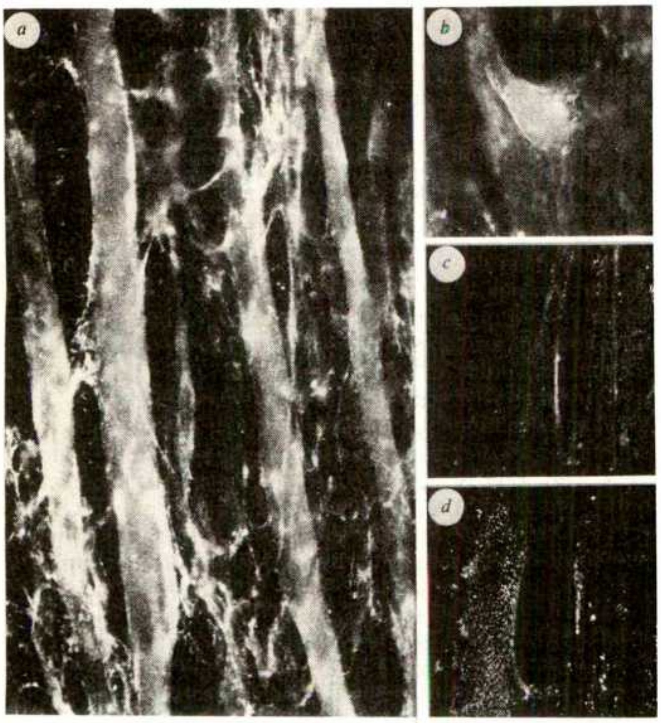

Fig. 2 Fluorescent antibody localization of extracellular matrix in C_2 myotube cultures. Cells were plated on tissue culture plastic and grown for 5 days in fusion medium, then incubated with rabbit antisera directed against the muscle basal lamina[4] at 1/100 dilution in low serum medium (1 h, 37 °C), followed by fluorescein isothiocyanate-conjugated goat anti-rabbit serum (Cappel) at 1/100 dilution in medium (1 h, 37 °C), washed with 0.15 M NaCl, 20 mM sodium phosphate, *p*H 7.2 (PBS) in 1 mM $CaCl_2$, mounted under 10% Gelvatol 20/30 (Monsanto), 20% glycerol in PBS, and examined with a Leitz Ortholux II microscope equipped with L2 (excitation bandpass (BP) 450–490, barrier BP 525/20) and N2 (excitation BP 530–560, barrier BP 580) filters. Reaction with: *a*, anti-muscle basement membrane collagen[4] (similar results were observed after incubation with anti-lens capsule collagen, data not shown); *b*, JS-I; *c*, JS-II; *d*, JS-III. ×236.

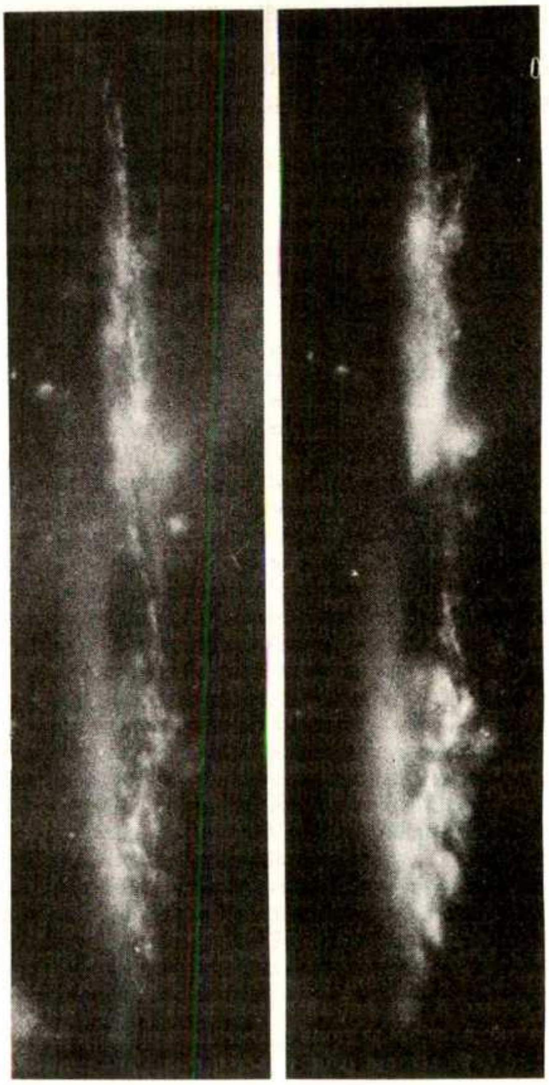

Fig. 3 Simultaneous localization of AChR clusters and basal lamina antigens in C_2 myotube cultures. Cells were plated on plastic coverslips, grown for 5 days in fusion medium and incubated with fluorescent reagents as before. Left, localization of JS-I antigen(s) by labelling with fluorescein-conjugated goat anti-rabbit serum as before. Right, AChR cluster in the same field observed after incubation with 50 nM rhodamine-conjugated α-bungarotoxin. Receptor clusters in control cultures, incubated with non-immune serum and photographed and printed in identical conditions, could be seen with rhodamine, but not fluorescein, filters. No receptor clusters were seen in cultures preincubated with unlabelled α-bungarotoxin (1 μM), followed by rhodamine-conjugated α-bungarotoxin. ×1,564.

In this context, the presence of synapse-specific basal lamina components in aneural C_2 muscle cultures does not imply that nerves are without influence on the normal appearance or localization of synaptic basal lamina components. We have shown previously that nerves can induce the appearance of synapse-specific basal lamina at sites of new endplate formation in adult muscle[26]. It will be of interest to investigate the role of nerves in the organization and production of synaptic basal lamina in myoblast cultures of different developmental ages.

Hypothalamic paraventricular nucleus is a privileged site for brain–pituitary interaction in long-term tissue culture

Alex J. Baertschi & Jean-Louis Bény

Department of Animal Biology, University of Geneva,
1211 Geneva 4, Switzerland

Beat Gähwiler

Preclinical Research, Sandoz Ltd, CH 4002 Basle, Switzerland

It is generally accepted that hypothalamic factors are released from the median eminence into the hypophysial portal vessels and exert a powerful control on the secretion of anterior pituitary hormones[1]. The brain sites involved in the synthesis of hypothalamic factors—particularly those that control ACTH secretion[2,3]—are, however, not yet established. It is also not known whether these sites are targets for pituitary hormone action, although recent anatomical[4] and physiological studies[5,6] suggest that pituitary hormones may reach the brain. For these reasons, we co-cultured[7,8] various hypothalamic explants from rat brain for 4 weeks with anterior pituitary. We report that during the third and fourth week *in vitro*, there is an approximately 10-fold increase in bioactive ACTH[9,10] in the medium of co-cultures prepared from the paraventricular nucleus and anterior pituitary, and that this increase is highly correlated with an increase (up to 10-fold) in concentrations of immunoreactive[11,12] arginine vasopressin (AVP). Hormone levels did not increase when basal hypothalamus was co-cultured with anterior pituitary, paraventricular nucleus with posterior pituitary, or supraoptic nucleus with anterior pituitary. Thus, we propose a specific interaction between anterior pituitary and paraventricular nucleus that results in a mutual enhancement ofeach other's peptide production.

The hypothalamus of Sprague–Dawley rats aged 6 to 7 days of either sex was cut within the frontal plane into slices about 400 μm thick, starting at the level of the optic chiasm (slice 1) and ending at the level of the posterior median eminence (slice 4). The paraventricular (PV) and supraoptic (SO) nuclei were punched out with a needle of 0.75-mm diameter by the Palkovits method[13] from slice number 1, and the basal hypothalamus (BH) from slice number 3 and 4. The tissues were cultured as explants[7,8] either alone or side by side with one half of an anterior pituitary (AP). Three half APs (three for technical reasons) were cultured alone as a control. The medium was collected and replaced every 7 days. After 28 days, the cultures were inspected by phase-contrast microscopy, and only those paraventricular and supraoptic explant combinations that displayed large size neurones were processed. The tissues were extracted in 0.1 M HCL, and the supernatants and pellets were stored at −20 °C pending hormone[9–12] and protein[14] assays.

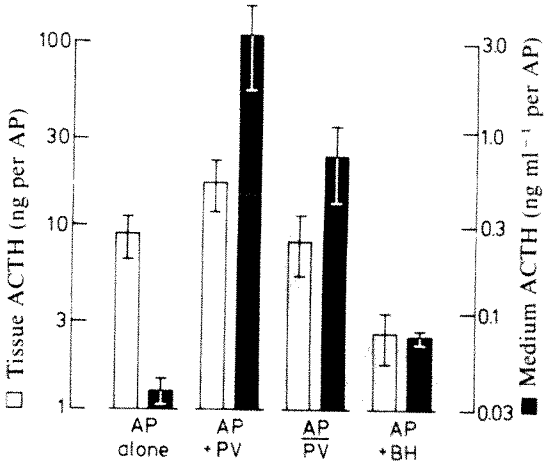

Fig. 1 Bioactive ACTH content (mean ± s.e.m.) of tissue (open bars) and medium (solid bars) from five to six hypothalamo-anterior pituitary cultures (AP, anterior pituitary; PV, paraventricular nucleus; BH, basal hypothalamus). AP+PV denotes a co-culture of the two explants in close apposition, as shown by the example of a AP+SO co-culture in Fig. 4*a*. In contradistinction, AP/PV signifies that the two explants were cultured on separate opposing coverslips within the same culture tube. The explants were embedded in a plasma clot and cultured in Falcon roller tubes. The medium (volume 1 ml) contained 25% horse serum, 25% Hanks' balanced salt solution, 50% basal medium (Eagle) and 6.5 mg ml^{-1} glucose[7,8]. The medium was replaced every week; hormone levels of the fourth week medium only are shown above. The tissue was homogenized in 700 μl of 0.2 M acetic acid and centrifuged at 15,000 r.p.m. and 4 °C for 15 min. The supernatant and the pellet, resuspended in 0.5 ml of 0.2 M NaOH, were frozen at −20 °C pending assays of hormones and proteins. Bioactive ACTH content of the tissues and media was measured by adding 5 or 10 μl of the 700 μl supernatant and 100 μl of the AP culture medium, respectively, to a 1 ml suspension of adrenocortical cells and by measuring the corticosterone secretion[9,10]. Note log display in this and all other figures.

When PV was co-cultured with AP for 28 days, the ACTH content of the medium (Fig. 1, solid bars, AP + PV) was 30 to 50 times larger than that of APs cultured alone or together with BH ($P < 0.025$). This large amount of medium ACTH was not due to a loss of ACTH from the tissue, since the tissue ACTH content (Fig. 1, open bars, AP + PV) was at least twice ($P < 0.05$) that found in any other type of cultures (AP alone, AP + BH). To test whether direct contact between the explants is necessary (see Fig. 4*a*), PV and AP were also cultured on separate opposing coverslips within the same tube. The ACTH content of the medium (Fig. 1, PV/AP) was at least 10 times larger than that of AP cultured alone, demonstrating that a factor released into the medium probably is responsible for the large increase in ACTH secretion induced by co-cultured paraventricular tissue.

The AVP contents of tissue (Fig. 2, open bars) and medium (dark columns) were about six times larger in PV–AP co-cultures than in PV cultures ($P < 0.05$). A trend towards elevated AVP levels was also observed when PV and AP were cultured on separate coverslips (AP/PV). Plotting the medium AVP and ACTH as a function of time in culture (Fig. 3) revealed a remarkable coincidence between the changes of both hormone

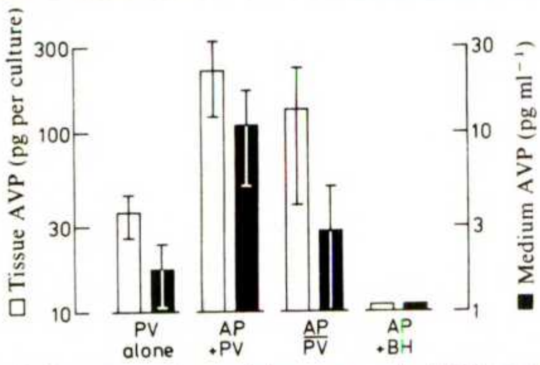

Fig. 2 Immunoreactive arginine vasopressin (AVP) content (mean ± s.e.m.) of tissue (open bars) and medium (solid bars) of the cultures shown in Fig. 1. For abbreviations, see Fig. 1 legend. The AVP content of the tissue was measured without extraction and the AVP content of the medium following vycor extraction by a specific radioimmunoassay[12,13]. AVP in the samples dilutes according to standard curve. The AVP tracer was from NEN, the AVP standard (500 IU mg^{-1}) is a gift of Drs K. Lederis and R. Mathison. The anti-vasopressin antibody, a gift of Dr J. Durr, does not cross-react with oxytocin, DD-AVP, ACTH, α-MSH, β-endorphin or with the enkephalins. The antibody was used at a dilution of 1:200,000. Recoveries were controlled in assay buffer and culture medium and varied from 58% to 70% between assays and ±3.5% within assays. Sensitivity was 0.25 pg per tube, about 0.4 pg per ml medium and 10 pg per culture. AVP was not detectable in AP + BH or BH alone. In AP/PV cultures where the two explants could be extracted separately, only the PV extract contained AVP. Separate experiments (not shown) indicate that co-cultures of PV with either posterior pituitary, hippocampus or cerebellar explants have AVP levels similar to those of PV alone.

levels which is also illustrated by a strong correlation between log(ACTH) and log(AVP) ($=0.91 \pm 0.04$).

In view of the possible role of AVP as a corticotropin releasing factor (CRF) *in vivo* and *in vitro*[10,15,16], we investigated whether the presence of vasopressin or vasopressinergic cells was sufficient to stimulate ACTH release from the anterior pituitary. We therefore added 100 pg of synthetic AVP (Ferring) once every week to anterior pituitaries. Medium ACTH levels were about 30% higher than controls ($P < 0.05$) and AVP levels ranged from 2–20 pg ml^{-1}, demonstrating that, although this increase in ACTH by AVP was far below that induced by co-cultured PV, very low amounts of AVP can exert significant CRF activity in this culture system. In another set of experiments, we determined whether other vasopressinergic cells display similar CRF activity. As illustrated in Fig. 4*b*, a co-cultured SO explant did not influence ACTH content and secretion by AP (Fig. 4*b*), whereas the presence of PV again elicited effects on AP qualitatively similar to those shown in the previous culture series.

This study clearly indicates that the PV region, and most probably not the hypophysiotrophic area, is a site for CRF synthesis. Stimulation[17], lesion[18,19] and histochemical[20–22] studies have previously implicated the PV in adrenocortical control. It remains to be seen if the CRF released from PV is identical with the one recently described[23], and if AVP is a cofactor in the control of ACTH secretion[24] by PV. However, the increased AVP levels in PV–AP co-cultures reveal a remarkable interaction between anterior pituitary and a specific region of the brain, and may have been caused by a known[25–27] or unknown growth factor from the pituitary or hypothalamus.

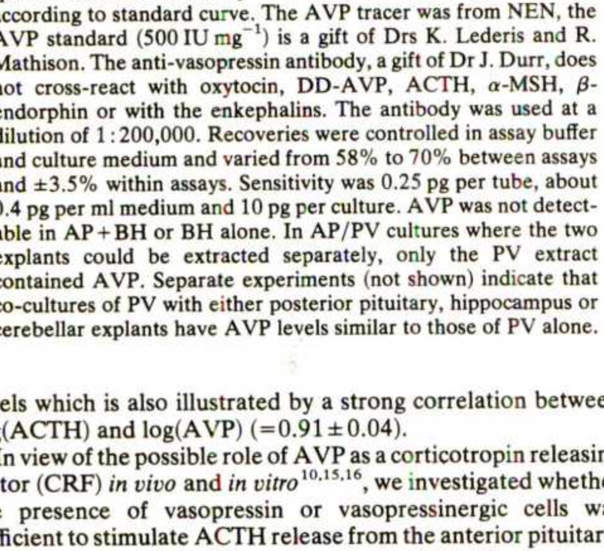

Fig. 3 Bioactive ACTH and immunoreactive AVP content of medium obtained from five individual AP–PV co-cultures as function of time *in vitro*. Tissues are the same as shown in Figs 1 and 2. Each symbol stands for one and the same co-culture. In PV cultures, AVP started to increase in half the cultures during the fourth week *in vitro*, whereas in AP cultures, ACTH gradually decreased from initial levels similar to those observed in AP + PV co-cultures.

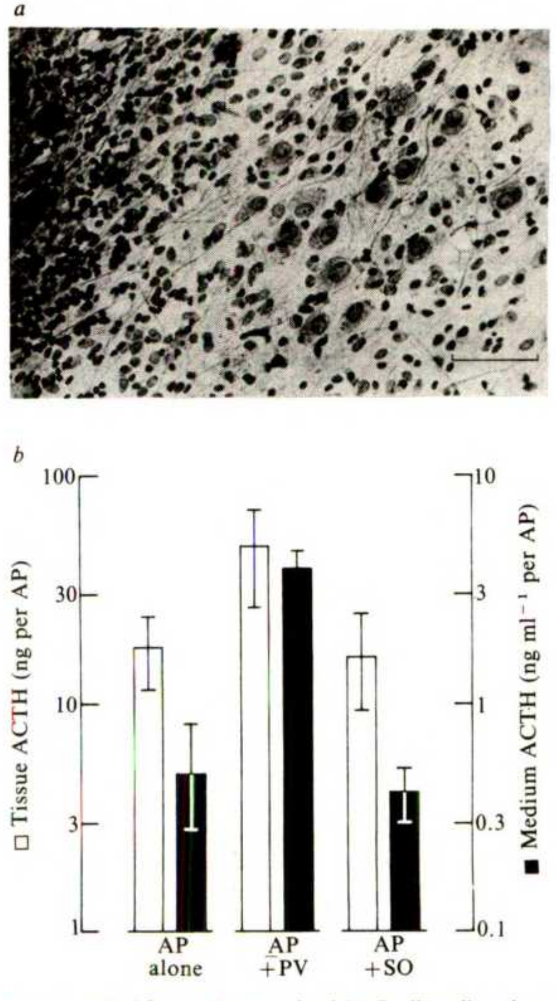

Fig. 4. *a*, AP–SO co-culture stained by Bodian-silver impregnation after 35 days *in vitro*. Note large cells with fine processes on right, and small anterior pituitary cells on left. Morphological aspects are similar in AP–PV co-cultures, although no morphometric analysis has yet been carried out. Scale bar, 60 μm. *b*, Bioactive ACTH content (mean ± s.e.m.) of tissue (open bars) and medium (solid bars) from five cultures (SO, supraoptic nucleus) after 4 week *in vitro*. AVP levels in SO cultures were about half those in PV cultures and, therefore, close to the detection limit. The existence of vasopressin was, however, clearly established by pooling three cultures of SO. The presence of AP had no detectable effect on AVP levels in co-cultures of AP + SO. Protein contents ranged from 180 μg (three half-anterior pituitaries) to 260 μg (hypothalamic cultures and co-cultures), and they are not significantly different in the various groups. Results from the set of experiments illustrated in this figure are presented elsewhere[28].

Our tissue culture approach opens new ways for identifying additional sites involved in the synthesis of CRF and other hypothalamic factors, and for exploring anterior pituitary actions on the brain.

This study was in part supported by Swiss NSF grant 3.581.0.79. We thank Ms L. Rietschin and M. Friedli for technical assistance, Dr J. Durr, Denver, for a sensitive and specific anti-vasopressin antibody, and Professor J.J. Dreifuss for valuable discussions.

Vasoactive intestinal polypeptide enhances muscarinic ligand binding in cat submandibular salivary gland

Jan M. Lundberg

The salivary secretion from the cat submandibular salivary gland induced by parasympathetic nerve stimulation is considered to be due to release of acetylcholine (ACh) which binds to muscarinic receptors and activates secretory elements[1]. Recent evidence suggests that cholinergic neurones in the cat submandibular gland contain and release another neurotransmitter candidate, vasoactive intestinal polypeptide (VIP)[2,3]. Although VIP *per se* does not induce salivary secretion, it potentiates the secretion induced by ACh infusions[2,3]. The present study offers a possible explanation for this potentiation by showing that VIP in physiologically relevant concentrations enhances the binding of muscarinic cholinergic ligands in the cat submandibular gland.

Membranes were prepared from the submandibular salivary gland of adult cats using previously described methods[4].

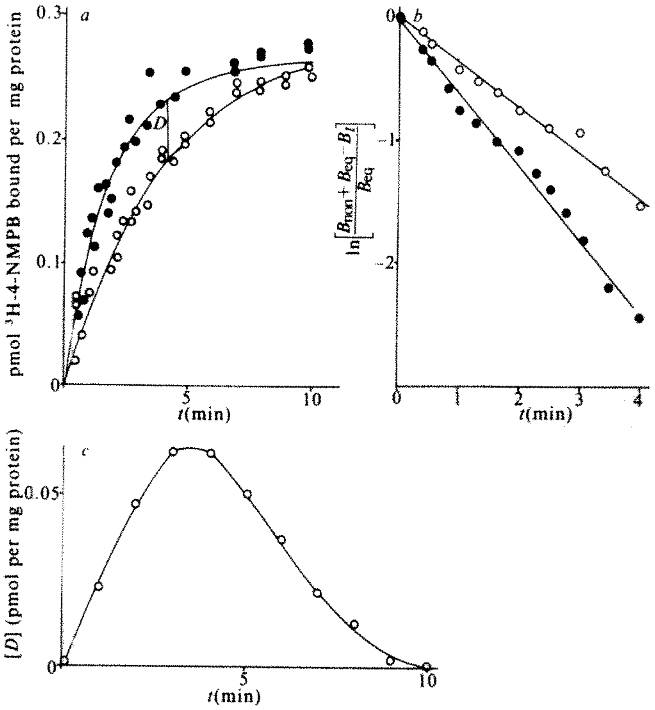

Fig. 1 *a*, Association rate of ^{3}H-4-NMPB (5.6 nM) to membranes from the cat salivary gland in the absence (○) and presence (●) of VIP (5 nM). Using a loose-fitting glass–Teflon homogenizer at 695 r.p.m., a 10% homogenate (w/v) of the glands in 0.32 M sucrose was prepared by 15 up-and-down strokes. After centrifugation at 1,000*g* for 5 min the resulting supernatant was subjected to further centrifugation at 10,000*g* for 40 min. The pellet thus obtained was resuspended in a modified Krebs–Ringer's buffer (137 mM NaCl, 2.68 mM KCl, 1.8 mM $CaCl_2$, 1.05 mM $MgCl_2$, 5 mM HEPES, 10 μM phenylmethylsulphonyl fluoride, 1 g l^{-1} glucose) and used in the binding studies without further treatment. All incubations with muscarinic ligands and VIP were carried out at 37 °C and the incubations were started by addition of VIP and ^{3}H-4-NMPB. Reaction was stopped by filtration through Whatman GF/B glass fibre filters and rinsing of the filters with 10 ml of ice-cold buffer. The filters were counted in a scintillation spectrometer on the next day in toluene/5% diphenyloxazole/0.1% *p*-phenylene phenyloxazole at an efficiency of 45–55%. The experiment was carried out three times with similar results. Data from one representative experiment are shown. Protein was determined according to Lowry *et al.*[17] using bovine serum albumin as standard. The points are the mean (±s.e.m.) of triplicate determinations. *b*, The semilogarithmic plot of the association rate data of *a*. These data were analysed by nonlinear least-square fit of the data to the following equation:

$$B_t = B_{non} + B_{eq}(1.0 - e^{-kt})$$

where B_t is the total amount ^{3}H-4-NMPB bound, B_{non} is the nonspecific binding which is equilibrated within seconds, B_{eq} is the amount of ^{3}H-4-NMPB bound in equilibrium and k is the observed pseudo-first order rate constant. This rate constant is influenced by several factors besides the concentration of ^{3}H-4-NMPB. The effect of VIP is demonstrated here but not analysed in detail because the VIP effect is transient (*c*), probably due to degradation and because the binding rate of VIP to its receptor is not known, only the onset of its effect on muscarinic binding. *c*, The transient effect of VIP (5 nM) on the association rate of ^{3}H-4-NMPB (5.6 nM). The difference (*D*) between the curves (*a*) in the presence and absence of VIP is plotted as a function of time.

Muscarinic receptor binding studies were performed using ^{3}H-*N*-methyl-4-piperidinyl benzilate (^{3}H-4-NMPB) as the labelled ligand[5]. All incubations were carried out at 37 °C immediately after preparation of the membranes. Highly purified porcine VIP was used in all incubations. The biological activity of the VIP solutions were also tested *in vivo* on cats, by measuring potentiation of the ACh-induced salivary secretion[3].

Figure 1*a* and *b* show that the association rate of the muscarinic antagonist ^{3}H-4-NMPB[5] at concentrations of 2–15 nM was increased in the presence of VIP (5 nM). This effect was smaller with 50 nM VIP. The effect of VIP was time dependent, being maximal at 3–4 min, and undetectable after 10 min (see Fig. 1*c*). The observed pseudo-first order rate constants[6] determined for the first 3 min (compare Fig. 1*a* and *b*) were 0.32 ± 0.07 and 0.52 ± 0.11 min^{-1}, respectively, in the absence and presence of VIP (5 nM). The difference was statis-

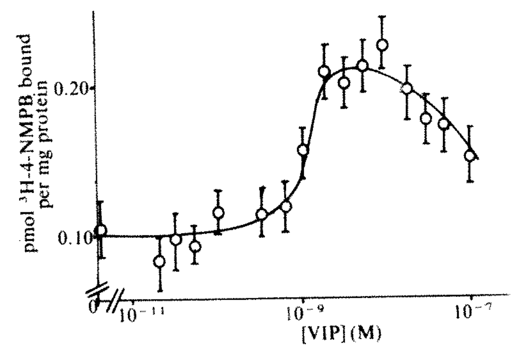

Fig. 2 The effect of VIP on binding to the muscarinic cholinergic receptors. Membranes were incubated with ^{3}H-4-NMPB (14 nM) and different concentrations of VIP (10^{-11}–10^{-7} M) for 2 min at 37 °C. Data shown are the mean (±s.e.m.) of quadruplicate determinations.

tically significant ($P < 0.001$). The dose dependence of the effect of VIP on ^{3}H-4-NMPB binding was then studied in pseudo-first order conditions. Figure 2 shows that at 2 min of incubation a bell-shaped curve of bound ^{3}H-4-NMPB versus VIP concentration was obtained, with a maximum between 3×10^{-9} and 3×10^{-8} M VIP. This curve was shifted to the right at longer incubation times, but the effective VIP concentrations were still in the nanomolar range.

At equilibrium conditions (60 min incubation), 0.30 pmol ^{3}H-4-NMPB per mg protein could be specifically bound both in the absence and presence of VIP, thus suggesting that only the affinity ($K_D = k_{diss}/k_{ass}$) and not the number of receptors is changed. The dissociation rate (k_{diss}) for ^{3}H-4-NMPB from the receptor was determined by starting the measurement after 2 min of incubation with ^{3}H-4-NMPB by addition of carbamylcholine (10 mM). No effect of VIP (1–50 nM) was detected on the dissociation rate of the ^{3}H-4-NMPB–receptor complex. Isoprenaline (10^{-7} M), adrenaline (10^{-5} M) and substance P(10^{-7} M), known to influence the function of the submandibular gland, were also tested, but none affected the association rate of muscarinic ligands with the receptor. To determine the tissue specificity of the effect of VIP on muscarinic ligand binding, rat cardiac membranes were tested in similar experiments (the auricles, which are known to have some VIP innervation, were removed). No effect of VIP on the association rate of ^{3}H-4-NMPB was detected in this preparation.

A 10-nM concentration was chosen from the plateau of the dose–response curve (Fig. 2) to examine the effects of VIP on muscarinic agonist binding. Figure 3*a* shows that in the presence of VIP, carbamylcholine behaved as a 1,000-fold more potent competitor of ^{3}H-4-NMPB binding than in the absence of VIP. Note that the slope of binding curves obtained in non-equilibrium conditions (Fig. 3*a*) is much higher than that in equilibrium conditions (Fig. 3*b*). The higher slopes may indicate cooperative interactions between carbamylcholine binding sites.

In equilibrium conditions (60 min incubation, Fig. 3*b*) VIP had no effect on the displacement of ^{3}H-4-NMPB by carbamylcholine. This 'absence' of effect is probably due to degradation of VIP during the long incubation. Figure 1*c* shows that the effects of VIP after 10 min have already disappeared, either due to degradation or desensitization. Analysis of VIP after exposure to tissue extracts or plasma indicates that the peptide is rapidly degraded ($t_{1/2} = 1$–1.5 min)[7,8], suggesting that degradation may be the major factor in the disappearance of its effects. Until stable VIP analogues are available it is not possible to evaluate the contribution of desensitization to disappearance of the effect. A similar disappearance of the effect of VIP over 10–20 min is observed when displacement of ^{3}H-4-NMPB by another agonist, ACh (10^{-9}–10^{-2} M), is studied. In the presence of VIP at 5 min incubation time but not with 10 and 20 min incubation, ACh behaves as a 10^5 times more potent agonist ($IC_{50} \approx 3\times10^{-9}$ M, Fig. 3*c*) than at equilibrium conditions.

The present findings suggest that VIP increases the affinity of muscarinic ACh receptors in the cat submandibular gland. Under physiological conditions VIP and ACh are probably released simultaneously upon activation of the secretory nerves[3]. Although VIP by itself does not induce salivation[2], the findings offer a possible explanation of the potentiating effect of VIP on ACh-induced saliva secretion[2,3]. Because, in the presence of VIP, the affinity of the muscarinic receptors for ACh increases 10^5-fold (Fig. 3*c*) a large increase can be expected in the secretory response which is governed by occupancy of muscarinic receptors[1]. Although it is early to speculate about the molecular mechanism of the VIP-mediated increase in muscarinic receptor affinity and association rate, it is relevant that equilibrium binding studies with muscarinic agonists suggest the existence of two or three interconvertible receptor populations having high and low affinity, respectively[9]. It is conceivable that occupancy of VIP receptors induces a shift from low- to high-affinity receptor conformation. (However, note that the data showing an effect of VIP on agonist binding (Fig. 3*a*, *c*) were not obtained in equilibrium conditions.)

Some of the muscarinic responses, such as increased cyclic GMP synthesis, seem to be linked to occupancy of low-affinity agonist binding sites, whereas other responses, such as phosphatidylinositol turnover, are apparently linked to both high- and low-affinity binding sites. (See refs 10, 11 for reviews.) Muscarinic responses involved in stimulation of secretion of the lacrimal cells[12], pancreatic cells[13] and parotid gland[14] relate high-affinity ($K_d < 1$ μM) agonist binding to increased Na^+ permeability. Accordingly, in the salivary gland VIP may switch muscarinic receptors to the high-affinity conformer and thereby increase their efficiency in changing Na^+ permeability and secretion.

The present data suggest that VIP receptors and muscarinic receptors interact in the plane of the membrane. Interaction between different receptors in the same membrane has been reported for muscarinic and β-adrenergic receptors in cardiac membranes[15] as well as for opiate receptors and nicotinic receptors[16] in the adrenal medulla.

Neuronal spread of scrapie agent and targeting of lesions within the retino-tectal pathway

H. Fraser

ARC and MRC Neuropathogenesis Unit, West Mains Road,
Edinburgh EH9 3JQ, UK

Scrapie is a transmissible encephalopathy of sheep and goats, and a number of mammalian species can be infected experimentally. Various strains of the transmissible agent are distinguishable on pathological and biological grounds in inbred mice[1–3]. The agents replicate in a variety of tissues, such as those of the lympho-reticular systems[1,4,5], but their pathological effects are confined to the central nervous system (CNS). The type, distribution and local intensity of the brain lesions vary, depending mainly on the agent strain, host genotype, route of infection and dose of agent. The principal type of lesion is vacuolar degeneration, typically with a bilaterally symmetrical distribution[6]. (Exceptional reports of its asymmetry can be attributed to 'class III' strains of agent[7], none of which is used in the present study.) Whether spread of infection around the body involves the migration of infected cells, the agent passing from infected to adjacent uninfected cells, or via a possible viraemic phase to cells remote from infected foci[8,9], or transport over considerable distances along nerves, possibly with trans-synaptic infection, is not known. There is evidence that infection spreads in the CNS from the thoracic spinal cord posteriorly and to the brain[10,11], but it is still unknown whether the spread is partly or exclusively via neurones, and which types of cell are infected. The finding that the retina became infected following intracerebral injection[12] has been interpreted as evidence for neural spread but this is not conclusive because it can be shown that tracers, for example, can travel from the subarachnoid space into the perineural space of the optic nerve to the epichoroidal and episcleral tissues of the eyeball[13–15]. I have now investigated whether lesions and infectivity can be targeted into a sensory nucleus following injection into a sense organ on one side of the body with the ipsilateral organ and nucleus acting as controls. The results show that scrapie agent can spread over a considerable distance along a nerve pathway.

The possibility that neural spread of scrapie infectivity could produce targeted lesions was tested by injecting the ME7 strain of scrapie into the right eye of inbred C3H/LacDk mice. Groups of mice were killed for histological examination at intervals of 155–260 days after injection; by 260 days the mice were within 2–3 weeks of the terminal stage of the disease. Haematoxylin- and eosin-stained transverse paraffin sections of their formol-saline-fixed brains were examined, using a standard procedure[16]. In mice killed at the earlier intervals, asymmetrical lesions were confined to the contralateral (left) superior colliculi and no lesions were apparent elsewhere in the brain. This tectal asymmetry continued throughout the series (Fig. 1*a*), becoming less frequent as lesions developed symmetrically in both the tectum and other regions of the brain. By 250 days post-injection only symmetrical lesions were present (Table 1). From about 70% of the way through the incubation period of 265 ± 3 (mean ± s.e.) days, an increasing proportion of cases showed a form of tectal asymmetry having severe degeneration of the contralateral side, but much less involvement of the ipsilateral superior colliculus (Fig. 1*b*), and low-grade symmetrical lesions elsewhere in the brain.

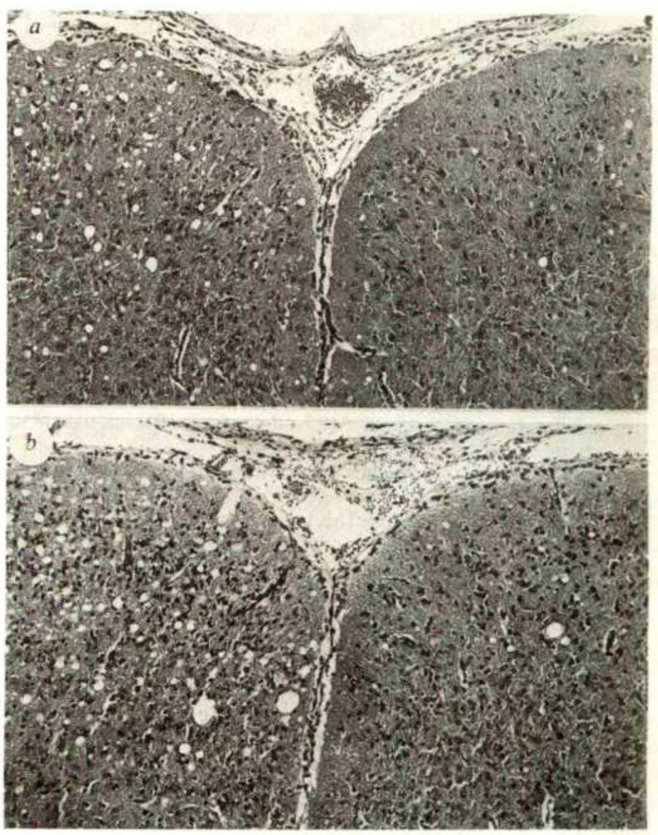

Fig. 1 Asymmetry of vacuolation in the left superior colliculus in C3H mice killed 185 (*a*) and 190 (*b*) days after right intraocular injection of ME7 scrapie agent. Haematoxylin and eosin stains used. ×78.

Retinal ganglion cells are known to project to and synapse with various brain nuclei, including the superior colliculi and lateral geniculate bodies[17]. In a few cases, low-grade vacuolation of the contralateral lateral geniculate nucleus occurred, but never with the consistency or severity seen in the optic tectum. This prominent asymmetry in the superior colliculi but not in the lateral geniculate nuclei is readily explained on several grounds. First, when injection routes which give fully symmetrical lesions (such as intracerebral or intraperitoneal injections) are used the ME7 agent in C3H mice produces severe vacuolation in the superior colliculi but only mild vacuolation in the lateral geniculate nuclei. Second the lateral geniculate is only a small homogeneous structure in rodents compared with its greater importance and complexity in carnivores and primates[17]; and third, there is more decussation to the superior colliculi than to the lateral geniculate nuclei[18]—90% to the latter in the mouse[19].

The observed distribution of infectivity in dissected optic nerves and superior colliculi is entirely in accord with the lesion data. Following injection into the right eye, at 68 days infectivity

Table 1 Numbers of C3H mice with vacuolar degeneration in the superior colliculi, at intervals after intraocular injection into the right eye with ME7 scrapie agent

	Days post-injection								
	155	161	167	185	190	200	216	232	251
Asymmetry of vacuolation in superior colliculus									
Left	2	4	2	2	1	2	0	1	0
Right	0	0	1*	0	0	0	0	0	0
Symmetrical lesions	1	0	1	0	0	1	2	0	2
No lesions	1	1	0	0	0	0	0	0	0
Incidence of asymmetry	2/4	4/5	3/4	2/2	1/1	2/3	0/2	1/1	0/2

Inoculum of scrapie agent was 10^4–10^5 ICLD$_{50}$ units per 0.002 ml of a 500*g* supernatant of terminal ME7-affected C57BL mouse brain homogenate.

* Data are available for 78 mice with asymmetrical vacuolation in the optic tectum following intraocular injection with scrapie from these and other unpublished experiments. This is the only deviant result in terms of sidedness and the possibility that the block was inverted during the preparation of sections cannot be excluded.

is present in its optic nerve and tract, and in the contralateral superior colliculus to which it projects, but absent from the optic nerve and tract from the left eye and from the ipsilateral superior colliculus. At 105 days there is 500 times more infectivity in the contralateral than the ipsilateral superior colliculus. We now have preliminary results from a much wider time series which confirms that these findings are part of a consistent trend and that the infectivity appears in the contralateral superior colliculus several weeks before the lesions.

The results reported here provide clear evidence that orthograde axonal spread can occur in scrapie in the CNS, which could account for the differences in titre found for the peripheral and central nervous systems, all pointing to neural spread[10-12]. This is also consistent with the recent evidence that the sympathetic system is a mode of entry of peripherally replicated scrapie into the thoracic spinal cord[20]. The extensive cross-over of retinal ganglion cell axons which occurs in adult rodents[19,21] would, if neural spread occurred, result in the targeting of the earliest lesions largely in the contralateral superior colliculus, as has been demonstrated with tracers of axoplasmic flow such as ^{35}S-methionine and horseradish peroxidase[22-24]. The alternative possibilities, of spread of infection via cell-to-cell contact in epineural glial cells, or of spread by extension through the subarachnoid space around the optic nerves and tracts, are clearly inconsistent with these results as neither method of spread would produce contralateral asymmetry restricted to the optic tectum. As an analogue of a central nervous pathway[25], the evidence for spread in the retino-tectal projection suggests that spread in the CNS may involve a wider range of central axons than previously thought, but does not rule out the possibility of other modes of spread, such as via the extracellular space and within and between glia.

It is now necessary to extend the observations described here, which are limited to the ME7 strain of scrapie agent, to other agents with different pathological manifestations, such as 79A agent in which white matter vacuolation is prominant[26], compared with 22C, where grey matter is involved exclusively, to test whether the targeting within the optic pathway can be shown to be even more specific.

Immune interferon release when a cloned cytotoxic T-cell line meets its correct influenza-infected target cell

A. G. Morris*, Yun-Lu Lin† & Brigitte A. Askonas‡

* Department of Biological Sciences, University of Warwick, Coventry CV4 7AL, UK
† National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK

T cells stimulated by mitogens[1], specific antigens[2], including viral antigens[3], and alloantigens[4] have been shown to produce immune interferon (IFN-γ). However, the exact circumstances of induction of IFN-γ in T cells have not yet been established, particularly the precise nature of the cell type producing the interferon. We have recently described[5] the selection and cloning of a BALB/c cytotoxic T(T$_c$)-cell line (L4) which grows in the presence of T-cell growth factor (TCGF), is Lyt-2 positive and kills H-2^d target cells infected with any type A influenza virus. The aim of the present study was to examine whether this cloned cytotoxic T-cell line produced IFN-γ on contact with the appropriate target cell. It was found that small amounts of IFN-γ were produced on co-culture of L4 with target cells, whereas L4 cells on their own released no detectable interferon. The pattern of antigenic specificity by L4 cells for interferon production resembled the requirements for killing in that T$_c$ cell mediated lysis was restricted to H-2^d targets infected with influenza A, but not influenza virus B strains, and interferon production was not prevented by a monoclonal antibody to the virus' haemagglutinin, which does not inhibit cytotoxicity while neutralizing the virus.

L4 T$_c$ cells were maintained in RPM1 1640 medium containing 10% fetal calf serum, ampicillin, kanamycin and 10% RS (supernatant from rat spleen cells activated by concanavalin A)[5]. The cytotoxicity of L4 declined rapidly during *in vitro* passage and regular recloning was necessary to maintain the line. ^{51}Cr-release cytotoxicity assays were carried out at regular intervals to survey cytotoxicity.

To examine interferon production, L4 T$_c$ cells were incubated with A/X31-infected P815 (H-2^d) target cells in the same conditions as the cytotoxicity assay except that the target cells were unlabelled. After 6 h incubation the cells were centrifuged lightly and interferon levels in the supernatant medium determined by titration on C3H10T$\frac{1}{2}$ mouse fibroblasts[6] using the inhibition of nucleic acid synthesis method[7] with Semliki Forest virus as challenge virus. Table 1 shows that L4 T$_c$ cells produce interferon on contact with A/X31-infected P815 cells, but that L4 T_c or infected P815 cells incubated alone for the same time period (6 h) do not. A monoclonal antibody (3/1) to the H3 haemagglutinin of A/Memphis/71, which neutralizes A/X31 virus infectivity[8] but does not block killing[9], does not prevent interferon production. P815 cells coated with UV-irradiated A/X31 virus, which do not act as targets, do not induce interferon. A/X31 virus alone added to L4 T_c cells at the same concentration used to infect P815 cells does not induce interferon in L4 T_c cells. Thus, production of interferon by L4 T_c cells required interaction with infected targets. The presence of free infectious virus was neither necessary nor sufficient for interferon production.

‡ To whom correspondence should be addressed.

We next determined whether the production of interferon was related to the recognition of appropriate antigens on the target cells. P815 cells infected with either A/X31 or A/USSR both act as targets for L4 T_c cells[5] and both induce interferon production (Table 2). P815 cells infected with B/HK, on the other hand, neither serve as targets for L4 T_c cells[5] nor induce interferon (Table 3).

Table 1 Cytotoxic T-cell clone L4 releases interferon on contact with targets infected with influenza strain A/X31

L4 T_c cells	P815 targets virus infection	Antiserum to HA*	Interferon production (U ml^{-1})	%Target cell lysis at K/T ratio 5/1	2.5/1
+	A/X31	–	100	29.4	27
+	–	–	<3	–	–
–	A/X31	–	<3	–	–
+	A/31	1/100	120	29	26.5
+	UV A/X31	–	<3	–	–

The cytotoxicity assay was carried out as previously described[17]. In brief, P815 cells infected for 1.5 h with 800 haemagglutinin units of virus and labelled with ^{51}Cr were washed three times and plated out at 10^4 per well in 96 round bottom microtitre plates. After 6 h incubation with L4 T_c cells in 0.2 ml at 37 °C, the plates were centrifuged for 5 min at 1,000 r.p.m; 0.1-ml samples were collected and radioactivity estimated in a γ-counter. % ^{51}Cr release = c.p.m. (experimental) – c.p.m. (spontaneous release)/c.p.m. (total) – c.p.m. (spontaneous release). K/T, killer/target cell ratio. To test the production of interferon, the assay was carried out in the same way in 0.2 ml per well except that the infected target cells were not labelled with ^{51}Cr, and K/T was 10:1 or 5×10^5 Tc cells per ml. The supernatant medium was collected and interferon assayed on C3H10T$\frac{1}{2}$ cells[7] by the INAS$_{50}$ method[7]. Briefly, replicate monolayers of cells were treated overnight with dilutions of interferon. The cells were then challenged with Semliki Forest virus and the extent of virus replication directly assessed by labelling with ^{3}H-uridine in the presence of actinomycin D to suppress cell RNA synthesis. Titres are quoted in units per ml and are approximately equivalent to international units of mouse IFN-$\alpha + \beta$ (there is at present no standard for mouse IFN-γ).

* Monoclonal antibody (3/1) to haemagglutinin of A/X31[8] which does not inhibit T-cell killing, but neutralizes infective virus[9].

We further correlated the production of interferon by L4 T_c cells with their ability to recognize and kill infected H–2^d targets but not infected H–2^b cells or infected H–2^{dm2} cells (B.A.A. and Y-L.L. in preparation). The dm$_2$ mutant lacks H–2L and H–2M molecules in the D region of the major histocompatibility locus. To test the killing of virus-infected cells derived from different mouse strains it was necessary to use lipopolysaccharide-stimulated B lymphoblasts as targets, which are not so efficiently killed by L4 T_c cells as P815 tumour cells. IFN-γ production was therefore low, but the amounts produced paralleled the killing obtained in cytotoxicity assays. Thus, whereas A/X31-infected BALB/c (H–2^d) lymphoblasts were killed by L4 T_c cells and induced interferon production, A/X31-infected lymphoblasts from C57/B16 (H–2^b) or BALB/c dm$_2$ mice (H–2^{dm2}) were neither killed by L4 T_c cells nor induced interferon (data not shown).

The type of interferon produced by L4 T_c cells interacting with A/X31-infected P815 cells was determined by antiserum neutralization and acid lability tests. Two antisera were used: a sheep antiserum to interferon produced by induction of C243 cells, and a rabbit antiserum to interferon produced by induction of mouse L cells (obtained from the NIH). Both antisera neutralize both mouse IFN–α and IFN–β but not IFN–γ. We found that both antisera failed to neutralize significantly the interferon produced by L4 T_c cells in conditions where interferon produced by Newcastle disease virus-induced mouse L cells (a mixture of IFN–α and IFN–β)[10] was completely neutralized. IFN–γ is unstable at pH 2 whereas IFN–α and IFN–β are both stable[11], the interferon produced by L4 T_c cells was completely destroyed by pH 2 treatment. Therefore by both these criteria the interferon produced was IFN–γ.

Table 2 Cytotoxic T-cell clone releases interferon on contact with targets infected with heterologous type A influenza virus

L4 T_c cells	P815 targets virus infection	Interferon production (U ml^{-1})
+	A/X31	45
+	A/USSR	50
–	A/X31	<3
–	A/USSR	<3

Experimental conditions were as described in Table 1 legend. The K/T ratio for interferon production was 8:1. At a K/T of 5:1, L4 cells lysed 17% of A/X31-infected and A/USSR-infected target cells.

Recently Marcucci *et al.*[12] have tested several T-cell clones, growing in TCGF, for IFN–γ production after mitogen stimulation. These clones, derived from AKR mice sensitized with picryl chloride, produced up to 800 units of IFN–γ per 10^6 cells. All the clones were Thy-1.1 antigen positive; but since they lacked detectable Lyt markers it was not possible to determine to which T-cell subpopulation they belonged. Our data indicate that Lyt-2-positive, target-specific T_c cells produce IFN–γ on contact with their target cell. There is a previous report of production of lymphokines by T cells of both Lyt-1- and Lyt-2,3-positive phenotype[13]. The characteristics of IFN-γ production resemble closely the characteristics of killing in viral antigenic specificity and H–2 restriction. As the virus alone does not induce IFN-γ, it seems that for IFN-γ production the L4 T_c cells need to 'see' the viral antigen in the context of cellular antigens. Accessory cells (such as macrophages) seem unnecessary for IFN-γ induction, although it is possible that they may augment interferon production and our data do not exclude the possibility that other T-cell subpopulations also produce interferon on appropriate stimulation. We also cannot exclude the possibility that the interferon is produced by the target cells following specific recognition by the T_c cell, but we think this unlikely because the interferon is type γ.

Table 3 Influenza type B virus-infected target cells do not induce interferon release by L4 cytotoxic T cells

L4T_c cells	Virus infection of P815 targets	Interferon (U ml^{-1})	Target cell lysis at K/T ratio 4:1	2:1
+	A/X31	120	20.3	14.5
–	A/X31	<3	—	–
+	B/HK	<3	2.1	0.8
+	—	<3	–	–
–	B/HK	<3	–	–

Assay conditions as in Table 1. L4 T_c cells ± influenza-infected P815 targets were incubated in a microtitre plate for 6 h at K/T ratio of 9:1 (10^4 target cells per well). Cells were centrifuged and the supernatant analysed for interferon. The data show interferon released by 4.5×10^5 L4 cells per ml over 6 h. A parallel assay was carried out with ^{51}Cr-labelled and A virus-infected target cells to measure the % ^{51}Cr released during a 6 h incubation at K/T ratios as shown.

The ability of T_c cells to produce interferon when they meet their histocompatible virus-infected target cell is of considerable importance. Immune T cells have been shown to protect against influenza virus infection[14], and clone L4 cells have been shown to protect against lethal influenza infection[15] and to reduce the replication of influenza virus in the lungs of infected mice. It was thought that T_c cells protect by killing cells early after virus infection, before virion assembly but after the expression of viral proteins on the cell surface. Our finding that L4 T_c cells produce IFN-γ after contact with their target adds another dimension to the role of T_c cells in preventing spread of virus. The IFN-γ produced would reduce spread of virus released from infected cells before killing occurred, and could also activate other immune effector cells, such as natural killer cells[16], which may be involved in resistance to virus infections. It could also serve to protect the T_c cells themselves from infection.

We acknowledge the technical assistance of Mr M. Drofiak and Miss C. Gillespie for interferon assays. We thank Dr P. Demant for a gift of BALB/c dm$_2$ mutant mice and Dr M. Tovey for sheep anti-IFN antiserum. A.G.M. was supported in part by a grant from the Cancer Research Campaign.

Phorbol-12,13-diester 12-ester hydrolase may prevent tumour promotion by phorbol diesters in skin

Mohammed Shoyab, Thomas C. Warren & George J. Todaro

Laboratory of Viral Carcinogenesis, National Cancer Institute,
National Institutes of Health, Frederick, Maryland 21701, USA

Tumour promoters are not themselves carcinogenic but can induce tumours in mice treated previously with an otherwise insufficient dose of certain chemical carcinogens[1–6]. One of the most potent tumour-promoting agents is 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA), initially isolated from croton oil[7]. The effects of tumour promoters are species specific[8]; croton oil, of which TPA is the most active component, does not act as a tumour promoter in rat, rabbit, guinea pig or hamster skin in conditions for which it is a potent tumour promoter in mouse skin[8–12]. Recently, we have purified the enzyme phorbol-12,13-diester 12-ester hydrolase (PDEH) to homogeneity from mouse and human liver cytosol[13]. This enzyme converts biologically active phorbol-12, 13-diesters to the inactive phorbol-13-monoester[13] in a dose-, time- and temperature-dependent manner. PDEH has been partially purified from hamster skin but is not detected in mouse skin, suggesting that the basis for the TPA tumour promotion only in mouse skin is a result of differences between the species in levels of TPA inactivating enzyme (PDEH) in the skin. We demonstrate here that responsiveness to TPA-induced tumour promotion is related to the level of PDEH activity in skin of all animals tested.

TPA elicits various biological and biochemical responses *in vitro* as well as *in vivo*[1–6,14–18]. High-affinity specific receptors for biologically active phorbol and ingenol esters have been reported for a wide variety of cells in culture as well as in animal tissues[19,20]. The lack of responsiveness of certain animal species to two-stage tumorigenesis is apparently not due to the lack of initiating carcinogenic activity because rabbit and hamster are highly susceptible to skin carcinogenesis caused by polycyclic aromatic hydrocarbons[21,22].

Table 1 Distribution of PDBu binding sites in skin of various species

Species	^{3}H-PDBu binding (ng per mg protein)
Mouse (BALB/c)	0.38
Rat (Fisher)	0.52
Guinea pig (N-2)	0.35
Hamster (Syrian)	0.23
Rabbit (NZW)	0.35
Cat	0.41
Dog	0.42
Rhesus monkey	0.37
Human	0.32

The shaved skins from adult animals were minced and suspended in 5 vol of cold phosphate-buffered saline (PBS) and disrupted with a polytron PT-10 (Brinkman) at 21,000 r.p.m. at 4 °C for 180 s. Four 30-s pulses at 30-s intervals were used. The crude homogenate was centrifuged at 105,000*g* for 1 h at 4 °C. Human skin from an autopsy specimen of a 5-yr-old female accident victim was similarly processed. The supernatant was removed and used for PDEH assay. The pellet was resuspended in the original volume of cold PBS. The binding of ^{3}H-PDBu to crude homogenate or pellet suspension was performed in duplicate in 12 × 75 mm disposable glass tubes (Kimax) in the absence or presence of 20 μg ml^{-1} unlabelled PDBu. The binding mixture contained 5 ng ^{3}H-PDBu ($\sim 4 \times 10^4$ c.p.m.), 0.2% final concentration of dimethyl sulphoxide (DMSO) and several concentrations of crude homogenate or pellet suspension in a total volume of 0.25 ml binding buffer (BB) consisting of Dulbecco's minimum essential medium (DMEM) containing bovine serum albumin (BSA, 1 mg ml^{-1}) and *N*,*N*-bis-(2-hydroxyethyl)-2-amine-ethane sulphonic acid (BES, 5 mM), adjusted to *p*H 6.8. After incubation at 23 °C for 30 min, tubes were chilled, 0.25 ml cold 4% calf serum (Colorado Serum Corporation) and 0.7 ml cold 25% polyethylene glycol (PEG 6,000) in 1 mM Tris-HCl *p*H 7.4 were added to each tube, the contents vortexed and the tubes allowed to stand at 4 °C for 15 min before being centrifuged (1,500*g* for 10 min at 4 °C). The supernatant solution was carefully drained off, the pellet resuspended in 2.5 ml of cold 10% PEG in 0.1 M Tris-HCl *p*H 7.4, and the tubes were again centrifuged as described above. The supernatant solution was removed and pellets solubilized in 0.8 ml of lysing buffer (0.01 M Tris-HCl *p*H 7.4, containing 0.5% SDS and 1 mM EDTA). The mixture was transferred to counting vials and 10 ml Aquassure (NEN) added to each vial. The vials were shaken vigorously and radioactivity determined using a Beckman β counter. The radioactivity bound in the presence of 20 μg ml^{-1} (50–200 c.p.m.) unlabelled PDBu was considered to be nonspecific and all data were corrected accordingly. Protein concentration was determined as described elsewhere[27]. The animal strains used are given in parentheses.

The phorbol diester inactivating enzyme (PDEH) is a single-chain, hydrophobic glycoprotein with a molecular weight (MW) of 60,000. It has an isoelectric point (*p*I) of 5, exhibits optimum activity at *p*H 7.5–8.5, and is heat- and acid-labile. Phenylmethylsulphonyl fluoride (PMSF) is a potent inhibitor of the enzyme, as are zinc, cobalt and fluoride ions. The amino acid composition and certain properties of the enzyme are different from purified porcine liver carboxy esterase (EC 3.1.1.1)[23,24]. The natural substrate(s) of PDEH are unknown; however, porcine liver esterase (Sigma) unlike PDEH, does not inactivate phorbol diester.

To investigate the restriction of TPA action in nonresponsive species, we studied the specific receptors for biologically active phorbol esters[19,20] and PDEH activity in skin of various species. Enzyme activity was measured by incubating ^{3}H-PDBu (phorbol-12,13-dibutyrate) and tissue extract at 37 °C for 30 min and then measuring the amount of remaining ^{3}H-PDBu by its binding to mouse brain membranous fraction (BMF), the richest source of receptors[20], for 30 min at 23 °C. We found that skin from all species tested contains TPA receptors, and that PDEH activity is absent from normal mouse skin, but present in very high levels in hamster, rat, guinea pig and rabbit skin. The distribution of PDBu binding sites in skin of various species is given in Table 1. Skin from all species (mouse, rat, guinea pig, hamster, rabbit, cat, dog, monkey and human) bound between 0.32 and 0.52 ng PDBu per mg protein. Thus, responsive and nonresponsive animals have roughly comparable levels of TPA receptors in their skin. Therefore, the lack of responsiveness to TPA characteristic of most rodent species except the mouse, is not due to the absence of specific TPA receptors.

Figure 1 shows that extracts from hamster, rat, guinea pig or

Table 2 Distribution of phorbol diester-12-esterase activity in skin of various species

Skin extract	Activity (^{3}H-PDBu cleaved; ng per mg protein)	TPA responsiveness (skin carcinogenesis)
Mouse (*nu*$^-$/*nu*$^-$)	<0.1	++
Heterozygote mouse (*nu*$^+$/*nu*$^-$)	<0.1	NK
Nude mouse (*nu*$^+$/*nu*$^+$)	1.7	–
Rat	22.7	–
Guinea pig	13.9	–
Hamster	100.8	–
Rabbit	7.8	–
Cat	<0.1	NK
Dog	<0.1	NK
Rhesus monkey	<0.1	NK
Human	0.1	NK

NK, not known. –, With low doses of TPA[15].

rabbit readily inactivated ^{3}H-PDBu, reducing its binding to the specific receptors in a dose-dependent manner. In contrast, extracts from mouse, cat, dog, monkey and human skin do not affect ^{3}H-PDBu binding to receptors. Failure of nude mouse skin to respond to low doses of TPA has been reported elsewhere[25]. Interestingly, nude mouse skin extracts contain small but significant amounts of PDEH whereas heterozygote mouse skin extracts, like wild-type mouse skin extracts, do not express any activity (Fig. 1). The levels of PDEH enzyme activity in skin extracts from various species are shown in Table 2. Hamster, rat, guinea pig, rabbit and nude mouse extracts cleaved, respectively, 100.8, 22.7, 13.9, 7.8 and 1.7 ng PDBu per mg protein, in our assay conditions. Mixing experiments demonstrated that the mouse skin extract contains a low level of a PDEH inhibitor, which can slightly decrease the hamster enzyme activity.

Table 3 summarizes a HPLC analysis of ^{3}H-PDBu treated with skin extract from various species. Extracts from hamster, rat, guinea pig and rabbit skin converted ^{3}H-PDBu to ^{3}H-13-PB (phorbol-13-butyrate) while there was no reduction in ^{3}H-PDBu nor appearance of other metabolites in samples treated with mouse, cat, dog, monkey or human skin extracts. HPLC analysis of ^{3}H-PDBu metabolite(s) (24 h after PDBu application) from mouse, hamster and guinea pig skin *in vivo* revealed that all the radioactivity recovered from mouse skin co-elutes with PDBu, whereas ~80% of the labelled material from hamster and ~96% radioactivity from guinea pig skin co-elutes with 13-PB, the rest remaining as PDBu. Thus, the direct application of PDBu to skin gave the same results as those obtained using skin extracts in an *in vitro* assay.

Table 3 HPLC analysis of ^{3}H-PDBu treated with skin extract from various species

Species	% Radioactivity eluted as PDBu	13-PB
Control	100	0
Mouse	100	0
Rat	0	100
Guinea pig	2.6	97.4
Hamster	0	100
Rabbit	35.2	64.8
Cat	100	0
Dog	100	0
Rhesus monkey	100	0
Human	100	0

^{3}H-PDBu (120 μl; ~16×10^4 c.p.m.) in BB, 0.2% final concentration DMSO and 2 mg of skin extract protein in 0.8 ml PBS were incubated for 1 h at 37 °C. ^{3}H-PDBu and products were extracted with a chloroform–methanol mixture (2 : 1), the organic phase containing almost all radioactivity dried under nitrogen, the material dissolved in 25 μl DMSO. Ten microlitres from each sample were analysed by HPLC using C_{18}-Bondapak/Porasil (Waters Associates)[13].

Our results show a close relationship between levels of PDEH activity in skin and responsiveness to TPA-induced tumour promotion in skin in all cases (mouse, hamster, rabbit, guinea pig and rat) for which data are available. Thus, TPA susceptibility of mouse skin, but not of other animal skin, may be due to the lack of expression of PDEH in this tissue. The high levels of PDEH in a tissue would inactivate TPA or other active phorbol esters, leading to insensitivity of that tissue to TPA-induced tumour promotion. On the basis of this observation, one would predict that TPA and related active diterpene esters would act as tumour promoters in cat, dog, monkey and human skin. An effective inhibitor of PDEH such as PMSF[13] would potentiate the action of TPA in skin and might make TPA-nonresponsive animals become sensitive to TPA. Conversely, inducers of the enzyme might render a responsive animal nonresponsive. Increasing the dose of TPA and/or TPA treatment frequency would probably enhance the susceptibility to TPA-elicited tumour promotion in PDEH-positive tissues. In addition, those tumour promoters which do not contain an ester group, such as dihydroteleocidin B[26], should be refractory to the action of PDEH and concomitantly, should act as promoting agents in PDEH-positive tissues, provided that they are not inactivated by some other enzyme in the tissue. Although PDEH is not expressed in mouse skin, very high amounts of the enzyme can be isolated from mouse liver and kidney. One would expect these tissues, like hamster, rat, rabbit or guinea pig skin, to be refractory to the various actions of the TPA-related tumour promoters.

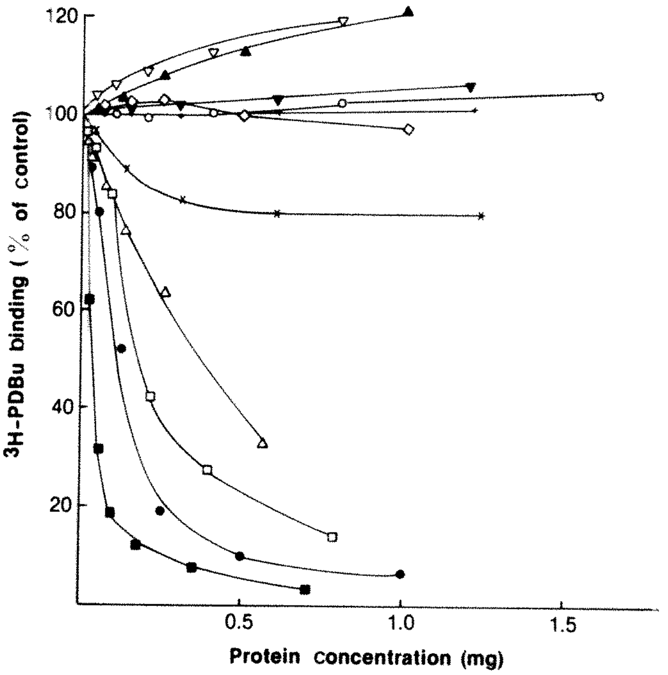

Fig. 1 Effects of protein concentration in skin extracts from various species on ^{3}H-PDBu inactivation. ^{3}H-PDBu (5 ng in 30 μl BB buffer), 0.2% final concentration DMSO and 0–200 μl of skin extract in PBS in a final volume of 0.23 ml were incubated in duplicate at 37 °C for 30 min. Tubes were placed on ice and 20 μl of murine BMF in PBS (50 μg protein) were added to each tube, the contents of the tubes were mixed and incubated at 23 °C for 30 min. After this time PDBu binding was determined as described in Table 1; 100% binding represents ~5,000 c.p.m. ○, Inbred mouse (*nu*$^-$/*nu*$^-$); +, heterozygote mouse (*nu*$^+$/*nu*$^-$); ×, nude mouse (*nu*$^+$/*nu*$^+$); ●, rat; □, guinea pig, ■, hamster; △, rabbit; ▲, cat; ▽, dog; ▼, rhesus monkey; ◇, human.

Calmodulin confers calcium sensitivity on secretory exocytosis

Richard A. Steinhardt & Janet M. Alderton

Department of Zoology, University of California, Berkeley, California 94720, USA

The cortical reaction at fertilization of a sea urchin egg results in the elevation of the fertilization membrane due to the exocytosis of cortical granules lying directly beneath the plasma membrane. These secretory granules are vesicles ~1 μm in diameter and can be easily observed in phase-contrast optics. Insemination of the egg results in the release of intracellular ionized calcium which acts as the trigger for the fusion of the cortical granules with the plasma membrane and the expulsion of their contents into the extracellular space[1,2]. Although Ca^{2+} is known to be involved in exocytosis, it has not yet been clearly demonstrated how the high sensitivity to calcium is conferred on exocytosis[3,4]. Here we examine the action of antibodies to calmodulin on the secretion of the cortical granules and demonstrate that calmodulin is responsible for the high calcium sensitivity of the cortical reaction and can be localized on the inner plasma membrane surface.

Baker and Whitaker have previously shown that the calcium sensitivity for cortical granule fusion with the plasma membrane is the same for both intact eggs and their *in vitro* preparation of isolated cortical surfaces[5]. Furthermore, they could stabilize the micromolar calcium thresholds for exocytosis by keeping the isolated surfaces in media containing millimolar concentrations of ATP[5]. They also demonstrated a strong inhibition by the antipsychotic drug trifluoroperazine, which suggested that a modulatory calcium-binding protein was involved in exocytosis[6].

Calmodulin is a ubiquitous calcium-binding protein used in many regulatory pathways and has been found in sea urchin eggs where it is known to activate NAD kinase[7-10]. The *in vitro* preparation for exocytosis allowed us to test directly the effects of antibodies to calmodulin without complications from poisoning other enzyme systems. Commercially obtained antibody to electrophoretically homogeneous native rat testis calmodulin was produced in sheep and the calmodulin-specific IgG was purified from other sheep immunoglobins and proteins by affinity chromatography on calmodulin–Sepharose[11]. Isolated cortical surfaces were prepared on poly-lysine-coated glass coverslips in the form of small (5 μl) chambers which could be directly observed with a Zeiss phase microscope while solutions were changed. These chambers were then incubated at 100% humidity and 16 °C in the isolation medium either alone or with calmodulin antibody or preimmune serum or calmodulin antibody plus excess calmodulin (purified from bovine testis)[12]. At the end of the incubation period, each chamber was photographed before and 60 s after testing with a single calcium concentration and the number of reacted cortical granules was counted.

When tested with the isolation medium alone, the calcium sensitivity of exocytosis remained constant for all periods of incubation with >70% discharge of the cortical granules within 60 s at 5 μM Ca^{2+}. Short periods of incubation (45 min) with the calmodulin antibody had no inhibitory effect but inhibition rapidly set in with longer periods, with the calcium threshold rising to 150 μM Ca^{2+} at 65 min and complete block even to 1 mM Ca^{2+} at 75 min. Figure 1 shows the results obtained with 75-min incubations, demonstrating the complete block induced by treatment with calmodulin antibody. In contrast, controls with isolation medium alone, preimmune serum or calmodulin antibody preincubated with excess calmodulin (at a ratio of 7 mol of calmodulin to 1 mol antibody) retain their high sensitivity to Ca^{2+}. A complete reversal of this block could be obtained by a further 10 min of treatment with calmodulin at a concentration of 2×10^{-5} M ($n = 3$). The rapid onset of the block after a delay and the much shorter period required for reversal with calmodulin suggests that a large excess of calmodulin is associated with each cortical granule–plasma membrane complex with only a relatively few calmodulin sites necessary for full calcium sensitivity and discharge at 5 μM Ca^{2+}. If this

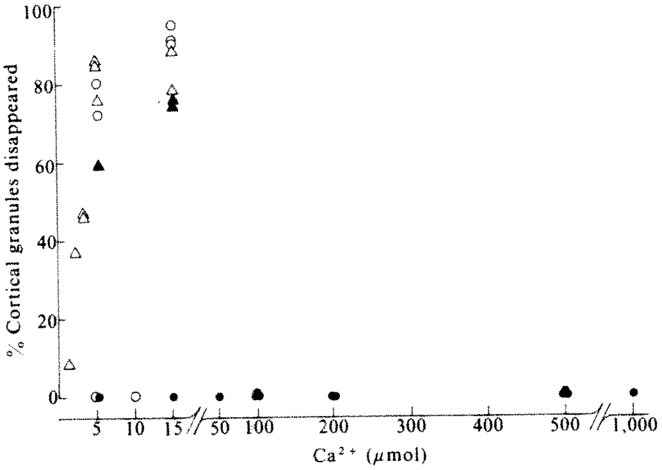

Fig. 1 Influence of antibody to calmodulin on the calcium sensitivity of exocytosis in isolated cortical surfaces. △, Controls in which the cortices were incubated in the isolation medium alone. ▲, Cortices incubated in isolation medium containing 750 μg ml^{-1} protein preimmune serum. ○, Cortices incubated in isolation medium containing 400 μg ml^{-1} sheep antibody to calmodulin plus 2×10^{-5} M bovine testis calmodulin[12]. This represents a molar ratio of 7 calmodulin to 1 sheep IgG. Antibody was preincubated with calmodulin for 1 h before being applied to the cortices. ●, Cortices incubated in isolation medium containing 400 μg ml^{-1} calmodulin antibody. Eggs of the sea urchin *Lytechinus pictus* were obtained as previously described[1]. Isolated cortical surfaces were prepared by the method of Baker and Whitaker[5] by sticking portions of egg cortices on glass coverslips with poly-DL-lysine in the following isolation medium: 250 mM potassium gluconate, 500 mM glycine, 10 mM NaCl, 10 mM HEPES, 10 mM EGTA, 5 mM Mg-ATP, 1 mM free Mg^{2+}, 10^{-7} free Ca^{2+}, pH 6.7. Ionized calcium and magnesium concentrations were calculated from the stability constants for EGTA[14]. The abscissa represents the ionized calcium concentration in the test solutions which were otherwise identical to the isolation medium except that no attempt was made to buffer calcium with EGTA at Ca^{2+} concentrations above 15 μM. Solution changes were made by placing a fragment of filter paper at one open end of the small (5 μl) glass coverslip chamber containing the cortical surfaces and flushing gently 20 μl of new solution through from the other end; this was repeated three times. After a 75-min incubation period at 16 °C, each chamber was viewed with a Zeiss inverted microscope (IM35) using a 63 power oil immersion phase objective. Each cortical preparation was photographed before and 60 s after the introduction of the test solution, with the time being measured from the time of the second flush of new solution. Preimmune serum and antibody to calmodulin were obtained from CAABCO, Houston, Texas. This non-precipitating sheep calmodulin antibody demonstrates cross-reactivity to calmodulin from vertebrates, invertebrates and plants, and exhibits <0.2% cross-reactivity to troponin C and no cross-reactivity to parvalbumin[11].

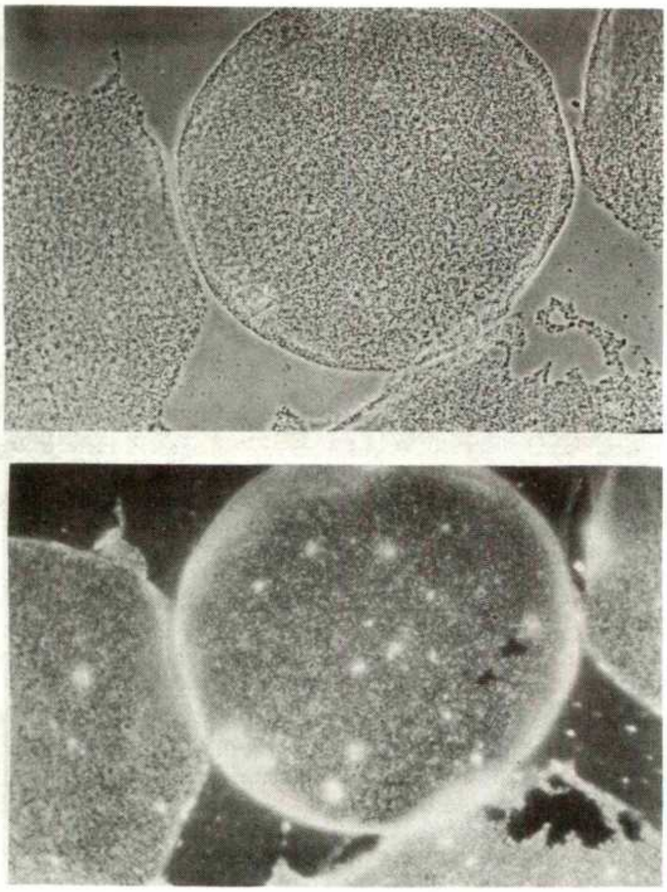

Fig. 2 Indirect immunofluorescent localization of calmodulin on the cytoplasmic side of isolated cortical fragments. Isolated cortical surfaces with only the cytoplasmic side exposed to medium were prepared as described in Fig. 1 legend on poly-lysine-coated glass coverslips. After following the same incubation procedure for 75 min with calmodulin antibody, the cortices were incubated for a further 60 min with fluorescein isothiocyanate-conjugated anti-sheep antibody prepared in rabbit, diluted 16-fold in the isolation medium (Miles). In controls in which the preincubation was with preimmune serum, calmodulin antibody adsorbed with excess calmodulin or isolation medium alone showed little or no staining except for occasional spots where the rabbit fluorescein isothiocyanate-conjugated antibody was trapped in a bit of debris or fold of the cortices. Zeiss epifluorescent microscope, ×63 phase optics. The stuck-down cortical diameter averages 120 μm.

explanation is correct, the delay reflects the time for the lower-affinity components of our heterologous antibody to bind and cover the last sites.

Immunofluorescent localization of calmodulin revealed heavy granular staining in the plane of the plasma membrane just beneath the layer of cortical granules (Fig. 2). During the repeated washes of the immunofluorescent procedure many of the cortical granules were washed away but staining was still found where they had been. Of course we cannot state definitely whether or not calmodulin was associated with the granules as well as the membrane, but it seems most likely that it is associated with both at the region of attachment. Having examined more than 24 samples, we suspect that the pattern of calmodulin staining corresponds to the cortical granule sites since the numbers are consistent with such a logical association; however, this conclusion cannot be convincingly reached using a light microscope and proof would require examination with anti-sheep ferritin-conjugated antibody using an electron microscope.

An important question arises as to whether the isolated fragments can be used as a model for real exocytosis or whether the *in vitro* system operates by some other means of granule discharge. Decker and Lennarz showed that in isolated fragments, a normal vitelline complex with the correct orientation was formed when cortical fragments were exposed to calcium ions[13]. Similar results have been obtained for stuck-down cortical fragments which, when exposed to 3 μM Ca^{2+}, undergo exocytosis, forming the perivitelline space and vitelline membrane (M. J. Whitaker and P. F. Baker, personal communication). Estimates of the peak calcium ion transient at fertilization from aequorin measurements fall in the same range (2.5–4.5 μM)[1]. These results and the identical sensitivity to calcium ions for both intact eggs suddenly lysed in Ca^{2+}-EGTA buffers and stuck-down cortical fragments strongly imply that identical mechanisms of exocytosis are involved[5].

To our knowledge, the results reported here are the strongest evidence to date for direct involvement of a known protein in fusion of a natural biological membrane and exocytosis at physiological concentrations of calcium ions. Our finding implies that calmodulin is bound to the inside surface of the plasma membrane and is integrally involved in the exocytosis of cortical granules, conferring the high sensitivity of calcium on that process. As other exocytotic systems also exhibit a similar dependence on calcium[3,4], we expect that calmodulin or other similar calcium-binding modulatory proteins will be shown to be involved in exocytosis generally.

This work was supported by NSF grant PCM 81-04294 to R.A.S. We thank Dr Joan Egrie for the gift of purified calmodulin and many useful discussions.

Measurement of changes in cytoplasmic free Ca^{2+} in fused cell hybrids

M. B. Hallett & A. K. Campbell

Department of Medical Biochemistry, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN, UK

The investigation of many problems in cell biology requires a method for studying chemical 'events' in living cells. For example, the measurement of cytosolic free Ca^{2+}, using Ca^{2+} indicators in giant cells, has provided vital evidence for the role of this ion in the activation of cells by electrical and chemical stimuli[1]. However, the incorporation of Ca^{2+} indicators into small cells (diameter <20 μm), without causing irreversible damage, has proved extremely difficult[1]. Recently, an elegant new technique has been reported[2] for entrapping within small cells a fluorescent Ca^{2+} indicator after hydrolysis within the cell of a membrane-permeant ester of the compound. We have developed a method, using Sendai virus, for fusing cells with erythrocyte ghosts containing photoprotein Ca^{2+} indicators and other membrane-impermeant chemiluminescent-labelled indicators[3,4]. Because of the sensitivity of chemiluminescent analysis, these indicators can be used at concentrations which do not significantly disturb the chemistry of the cells. The ultimate aim was to establish a cell system in which free Ca^{2+}, oxygen radicals and cyclic nucleotides could be directly monitored. Here we report the incorporation of the photoprotein, obelin[5], an indicator of free Ca^{2+}, into small mammalian cell hybrids.

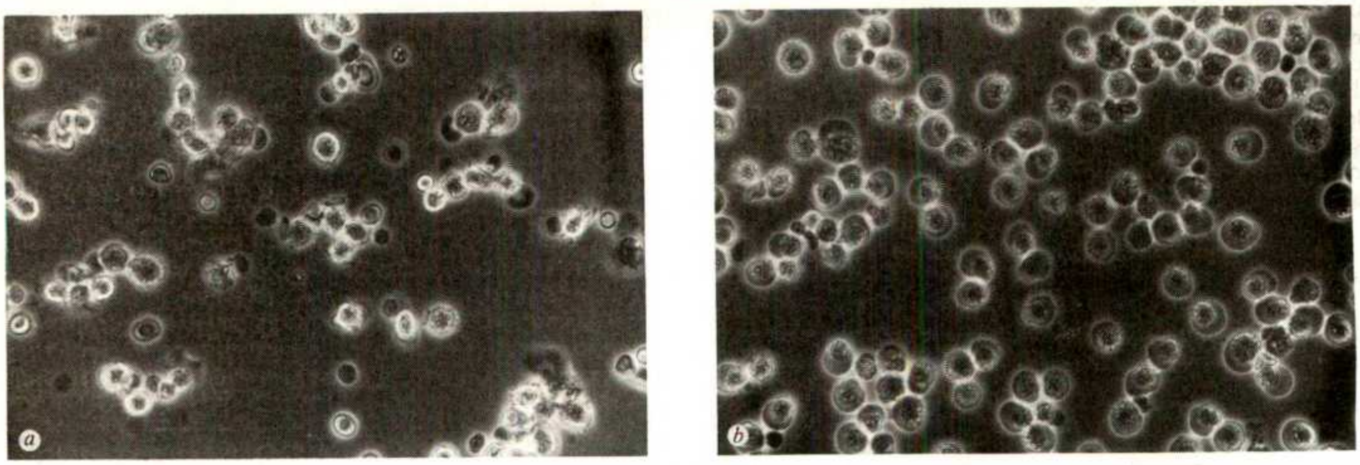

Fig. 1 Phase-contrast microscopy of unfused cells and hybrids. Human erythrocyte ghosts containing obelin were prepared from washed human erythrocytes by lysing preswollen erythrocytes[6] in 10 mM TES (*N*-Tris-(hydroxymethyl)-methyl-2-amino-ethanesulphonic acid, treated with Chelex-100, see ref. 1) and adding obelin (1–10 μl) for 10 min at 0 °C. Isotonicity was restored by addition of KCl (pure) to give a final concentration of 150 mM, and the ghosts were resealed at 37 °C for 30 min. Rat polymorphonuclear leukocytes were isolated from the peritoneal fluid of rats previously injected intraperitoneally with sodium caseinate as previously described[7]. Fusion was achieved by resuspending a mixture of erythrocyte ghosts (5×10^7) and polymorphonuclear leukocytes (5×10^7) in 100 μl of ice-cold medium containing 150 mM NaCl (pure), 10 mM TES–Chelex, 0.25 mM uranyl acetate and 1,500 haemagglutinating units of UV-inactivated Sendai virus, *p*H 7.4. After 10 min at 0 °C, the suspension was incubated at 37 °C for a further 30 min, washed and resuspended in 120 mM NaCl, 4.8 mM KCl, 1.2 mM KH_2PO_4, 1.2 mM $MgSO_4$ and 25 mM HEPES, *p*H 7.4. Unfused polymorphonuclear leukocytes were separated from the hybrids by centrifugation through a preformed Percoll gradient (density 1.05–1.09 g ml^{-1}) at 1,000*g* for 20 min. *a*, Unfused mixture of human erythrocyte ghosts and rat polymorphonuclear leukocytes; *b*, hybrid cells, showing the granules associated with the polymorphonuclear leukocyte portion of the hybrid and the clear cytoplasm associated with the ghosts. Cells and hybrids were stored for 24 h at 4 °C before the photographs were taken.

Human erythrocyte ghosts containing obelin were prepared by a modification of the 'pre-swell' method of Rechsteiner[6]. Rat polymorphonuclear leukocytes were prepared after intraperitoneal injection of sodium caseinate[7]. Fusion was achieved by resuspending a mixture of erythrocyte ghosts and polymorphonuclear leukocytes in a medium containing Sendai virus (Fig. 1). More than 99% of cells in the final preparation were hybrids, as observed by light microscopy (Fig. 1). Oxygen radical formation detected by chemiluminescence was used to monitor a Ca^{2+}-dependent response in the hybrids[8]. A major problem associated with using Sendai virus as a fusogen has been that the virus causes cell lysis. A crucial factor in our method is the use of uranyl acetate in the fusion medium[9], which reduces virus-induced haemolysis of the ghosts from 89% to 2.5%, as measured by haemoglobin release. A second important feature is the absence of extracellular Ca^{2+} during fusion. Although the role of intracellular Ca^{2+} in cell fusion is controversial[10], we have demonstrated that an increase in intracellular free Ca^{2+} is an early event in ghosts exposed to Sendai virus and occurs before fusion (P. Fuchs, M.B.H and A.K.C., unpublished observations). This rise in free Ca^{2+} can cause consumption of >90% of the obelin. However, because this large rise in free Ca^{2+} is not essential for fusion, extracellular Ca^{2+} was omitted from the fusion medium so as to maintain the obelin active in the hybrids. The hybrids were capable of responding to a phagocytic stimulus (latex beads), which induces the production of oxygen radicals, detected by luminol-amplified chemiluminescence[7,8]. The response of the hybrid cells to latex beads was 50–80% of that in the unfused polymorphonuclear leukocytes.

We have developed a method[11,12] for quantifying the extent of fusion between the erythrocyte ghosts and polymorphonuclear leukocytes using the activation of complement by two antisera, one specific for the human erythrocyte ghosts and the other specific for the rat polymorphonuclear leukocytes. Formation of

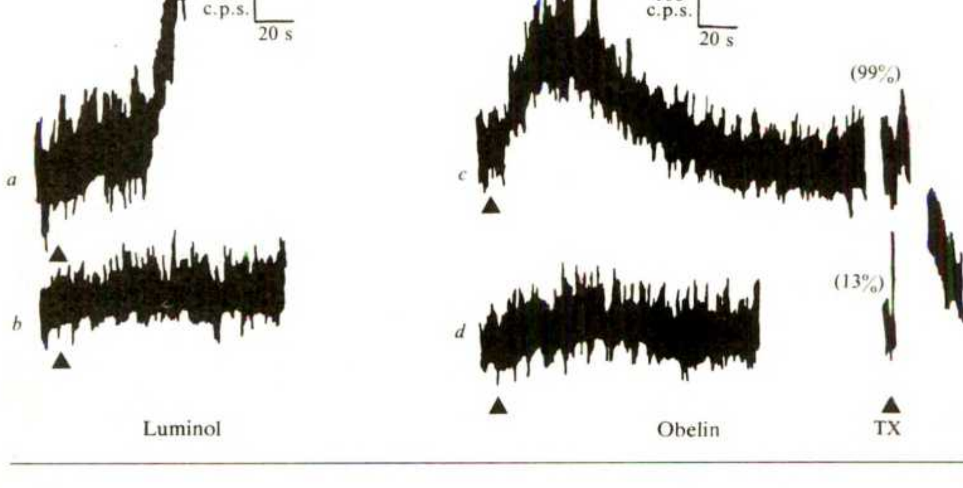

Fig. 2 Obelin luminescence and luminol-amplified chemiluminescence from unfused cells and hybrids. Approximately 5×10^6 hybrids or 10^7 total cells in the unfused mixture were resuspended in 500 μl of Krebs–Ringer HEPES buffer (120 mM NaCl, 4.8 mM KCl, 1.2 mM $MgSO_4$, 1.2 mM KH_2PO_4, 1.3 mM $CaCl_2$, 0.1% bovine serum albumin, (w/v), 25 mM HEPES, *p*H 7.4) and preincubated for 2 min at 37 °C with either anti-human erythrocyte antisera (20 μl) (*a*, *b*) or anti-polymorphonuclear antisera (20 μl anti-rat 5′-nucleotidase antiserum) (*c*, *d*). Oxygen radical formation was monitored after addition of 10 μM luminol to the extracellular medium by chemiluminescence (*a*, *b*). Obelin luminescence was monitored in the absence of luminol and consumption of obelin was demonstrated by addition of Triton X-100 (scintillation grade 2%, w/v) at the end of the time period (TX), allowing all remaining obelin to be stimulated (*c*, *d*). Values in parentheses show the % obelin consumed. *a*, *c* Show responses from hybrids and *b*, *d* responses for unfused cells. At the arrow, human serum (50 μl in 500 μl of Krebs–Ringer HEPES buffer) as a source of complement was added to the suspension. The vertical scale shows luminescent counts per second (c.p.s.) and the horizontal scale shows time.

the complement terminal attack complex on the ghost membrane results in a rapid rise in the intracellular free Ca^{2+} concentration after binding of complement component C9 (ref. 12). Activation of complement by anti-rat polymorphonuclear leukocyte antibody bound to the polymorphonuclear leukocyte surface stimulates oxygen radical formation from the polymorphonuclear leukocyte, and this effect also requires[7] Ca^{2+} and complement component C9. After fusion of the erythrocyte ghosts with polymorphonuclear leukocytes, observed microscopically, complement activation by anti-rat polymorphonuclear leukocyte antibody stimulated obelin luminescence and complement activation by anti-human erythrocyte antibody stimulated oxygen radical formation from the hybrids (Fig. 2). In contrast, no obelin response was detectable from the unfused cell mixture when complement was activated by anti-rat polymorphonuclear leukocyte antibody and no oxygen radical formation was detectable when complement was activated by anti-human erythrocyte antibody (Fig. 2). In the conditions described for Fig. 1, 60–80% of the obelin originally entrapped in the ghosts was transferred to the hybrids.

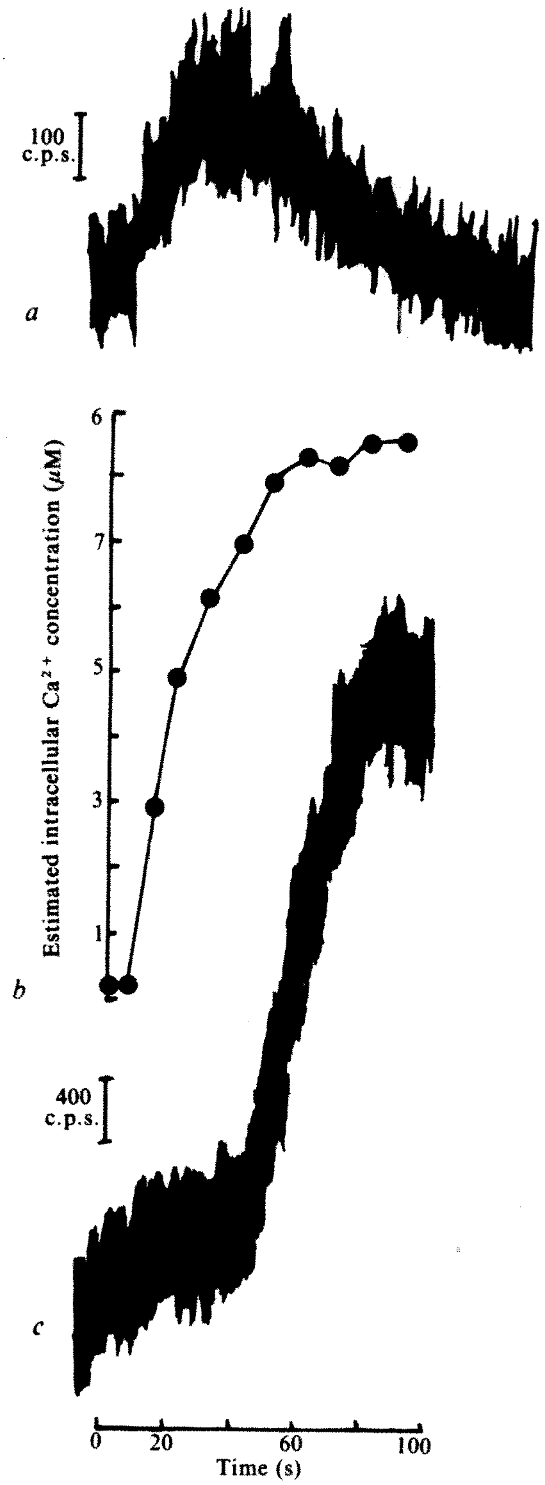

Fig. 3 Relationship between intracellular Ca^{2+} and oxygen radical production from the hybrids. Hybrids were stimulated with anti-polymorphonuclear leukocyte antibody plus complement as described in Fig. 2 legend. *a*, Obelin luminescence; *b*, the cytoplasmic Ca^{2+} estimated from *a*. The rate constant of obelin luminescence was calculated from *a* at various times, and converted to a free Ca^{2+} concentration by reference to a calibration curve relating rate constant to free Ca^{2+} in the presence of 2 mM Mg^{2+} (see ref. 12). *c*, The luminol-amplified chemiluminescence resulting from oxygen radical formation, accompanying stimulation of the hybrids.

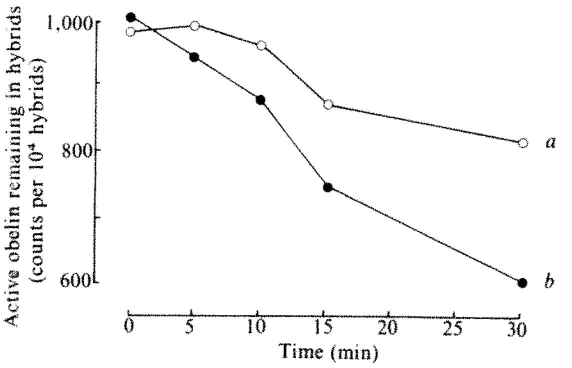

Fig. 4 Consumption of obelin in hybrids stimulated by chemotactic peptide. Total active obelin remaining in the hybrids after various times of incubation was measured by addition of 1% Triton X-100 (scintillation grade) in Krebs–Ringer HEPES buffer to samples of the suspension to stimulate all remaining active obelin. *a*, Incubation at 37 °C with *N*-formyl-L-methionyl-L-leucyl-L-phenylalanine (1 μM dissolved in dimethyl sulphoxide, final concentration 0.1%). *b*, Dimethyl sulphoxide (0.1% v/v) alone. From the curves the mean rate constants of obelin consumption were calculated and compared with calibration curves of obelin luminescence against Ca^{2+} concentration. Assuming the free Mg^{2+} concentration within the hybrid to be ~2 mM, the free Ca^{2+} concentration within the hybrids was estimated to be 0.7 μM (*a*) and 0.3 μM (*b*).

An important application of this fusion technique is the quantification of cytoplasmic free Ca^{2+} in both resting and stimulated cells. The cytoplasmic free Ca^{2+} in the hybrids was estimated by relating the rate constant of obelin to free Ca^{2+} (refs 1, 12). Before fusion, the resting free Ca^{2+} concentration in the ghosts, in the presence of external calcium (1 mM), was ~0.5 μM. However, the estimated resting free Ca^{2+} in the hybrids was lower, ~0.1–0.3 μM assuming an intracellular free Mg^{2+} concentration of 2 mM. Activation of complement by anti-polymorphonuclear leukocyte antibody bound to the hybrid surface resulted in a rise in intracellular free Ca^{2+} which reached a plateau of 8 μM within 1 min (Fig. 3). The initial rise in intracellular free Ca^{2+} preceded that in luminol-dependent chemiluminescence by ~40 s. The chemotactic peptide *N*-formyl-L-methionyl-L-leucyl-L-phenylalanine stimulated oxygen radical formation in the hybrids, detected by luminol-dependent chemiluminescence. It also stimulated a prolonged increase in obelin consumption, the mean free Ca^{2+} concentration over 30 min corresponding to ~0.7 μM, twice the resting cytoplasmic Ca^{2+} concentration (Fig. 4). Phagocytic stimulation of the hybrids produced a low level of endogenous luminescence which was not caused by obelin but was the result of oxygen radicals formed within the cells. No obelin luminescence was observed above this endogenous luminescence, and no increased consumption of obelin was observed. We conclude that this phagocytic stimulus did not cause a prolonged rise in intracellular free Ca^{2+}, despite the fact that oxygen radical formation required extracellular Ca^{2+} and was blocked by the calmodulin inhibitor trifluoperazine[7]. The extent of oxygen radical formation caused by various stimuli did not, therefore, correlate with the length of time of the increase in free Ca^{2+}.

The presented method, although limited to cells which will fuse with erythrocyte ghosts, has applications for incorporating other indicators into the cytoplasm of hybrids which are still capable of responding to a cell stimulus. For example, the chemiluminescent compound luminol, which has been used here extracellularly (Figs 2, 3) to monitor oxygen radicals within the phagosomes, has also been incorporated into the cytoplasm of the hybrids to monitor cytoplasmic oxygen radical formation. Furthermore, macromolecular inhibitors of cell function, such as antibodies, can be incorporated into the hybrids[13]. The uniform distribution of these compounds within our hybrids has been demonstrated by observing fluorescein-labelled albumin and immunoglobulin originally entrapped in the ghosts. This method therefore provides cell biologists with an exciting new tool for studying chemical changes in living cells.

We thank Dr J. P. Luzio for the gift of anti-5′-nucleotidase antiserum, the director and staff of the Marine Biological Association, Plymouth, Professor H. Harris for initial donation of virus, Mr N. Bishop for help in growing the virus, and Dr R. L. Dormer for helpful discussions. This work was funded by the SRC and the Arthritis and Rheumatism Council.

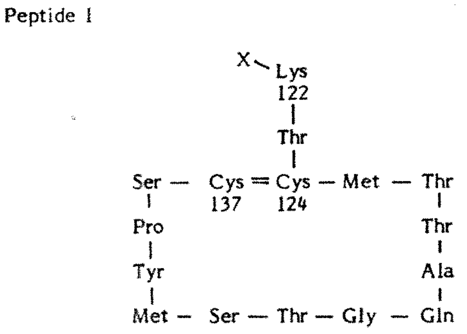
§ Department of Biochemistry, Medical College of Virginia, Richmond, Virginia 23298, USA

A formalin-inactivated hepatitis B virus (HBV) vaccine has been produced in several laboratories (for review, see ref. 1). The sole source of material for these vaccines has been 22-nm lipoprotein particles composed of hepatitis B surface antigen (HBsAg) and derived from plasma of persons chronically infected with HBV. Such a source presents potential hazards in view of unknown factors that may be present in the plasma, and as high-risk populations are immunized, sources of plasma containing large quantities of HBsAg will become scarce. In addition, no tissue culture system has been developed for the propagation of HBV. The possibility of a synthetic peptide vaccine[2,3] for HBV had been suggested[2,3] following studies carried out with tobacco mosaic virus[4,5] and MS-2 coliphage[6]. This possibility recently became a reality when the amino acid sequence for HBsAg was deduced from the nucleotide sequence of the cloned HBV genome (for a review, see ref. 7). More recently a portion of the major polypeptide derived from HBsAg, with a calculated molecular weight of 25,000 (P25), has been sequenced[8]. Lerner *et al.*[9] have described a similar approach towards HBV synthetic peptides. Antibody to HBsAg (anti-HBs) was raised in rabbits inoculated with three or four doses of a series of peptides, each containing 14–15 amino acid residues, but only after covalent linkage of the peptides to a carrier protein. Activity was also found after multiple injections of a peptide containing 34 amino acids. We have now synthesized two cyclic peptides containing disulphide bonds, both unrelated to those prepared by Lerner, from a hydrophilic region of the major viral polypeptide, which elicited an antibody response in mice after a single injection without linkage to a protein carrier.

The first major step in our work was the selection of those amino acid residues containing specific HBsAg determinants using a computer analysis of the amino acid sequence of P25 to predict the secondary structure of the molecule according to the technique of Chou and Fasman[10]. The protein hydrophobicity was estimated using the amino acid assignments of Bull and Breese[11]. HBsAg was found to contain predominantly β structure interrupted with a series of β turns. Three highly hydrophobic regions are located between residues 1 and 42, 66 and 108, and 146 and 226, and two hydrophilic regions between residues 43 and 65, and 109 and 145. The latter hydrophilic regions are probably exposed on the intact particle and, consequently, β turns in these regions would represent potentially exposed antigenic determinants[12].

The region between amino acids 117 and 137 was chosen for our first synthesis because a cyclic disulphide could be formed between Cys 124 and Cys 137 (see Fig. 1). Thus by locking the conformation of the potential β turns at residues 129–132 and 135–137, we expected to obtain a polypeptide more native in structure[7]. A serine was substituted for the cysteine at position 121 in the *ayw* sequence[8] to allow formation of a single cyclic disulphide. Lysine was substituted for Arg 122 to provide a handle for cross-linking to other proteins, if needed, before injection into animals. The selected peptides were synthesized by solid-phase methodology[13] on a Schwarz Bioresearch synthesizer modified for computer control[14]. Butyloxycarbonyl-*S*-*p*-methoxybenzyl-L-cysteine was coupled to *p*-hydroxymethyl-phenylacetamidomethyl polystyrene using dicyclohexylcarbodiimide with a catalytic amount of 4-*N*,*N*-dimethylaminopyridine[15,16]; the loading was 0.09 mM per g of resin. For the synthesis, the α-amino groups were protected with t-butyloxycarbonyl (t-BOC) and the side chain-protecting groups were as follows: benzyl ethers for the hydroxyl of serine and threonine, dichlorobenzyl ether for the phenolic hydroxyl of tyrosine and carbobenzoxy for the ϵ-amino group of lysine. Trifluoroacetic acid (40% in CH_2Cl_2) was used to remove the t-BOC, and the resulting salt was neutralized with *N*,*N*-diisopropylethylamine (5% in CH_2Cl_2). Dicyclohexylcarbodiimide was used to couple the t-BOC amino acids; hydroxybenzotriazole was added to the coupling reaction of glutamine to



Peptide 2 contains 5 additional amino acid residues:

Fig. 1 Amino acid sequences of synthetic peptide 1 (molecular weight 2,219) and peptide 2 (molecular weight 2,739).

0028-0836/82/020158—03$01.00

suppress side chain dehydration. The specific steps of the synthesizer programme have been published elsewhere[15,17].

The protecting groups were removed and the peptide was cleaved from the resin at 0 °C with anhydrous hydrogen fluoride containing 10% anisole and 1% ethanedithiol as scavengers. The HF reagent was removed under vacuum at 0 °C, and then the peptide was precipitated and washed with anhydrous ether. After extraction of the peptide from the resin with trifluoroacetic acid, the solvent was evaporated at 15 °C and the peptide again precipitated with ether. The ether was decanted after centrifugation and the pellet dissolved in 1 M Tris/6 M guanidine hydrochloride; the *p*H of this solution was immediately adjusted to 8. The solution was desalted on a BioGel P-2 column equilibrated in 0.1 M ammonium bicarbonate, and the peptide-containing fractions were pooled and lyophilized.

The cyclic disulphide was formed by oxidation of a dilute solution of the peptide with potassium ferricyanide according to the procedure of Felix *et al.*[18]. The solution was lyophilized and desalted on a BioGel P-2 column, and the peptide further purified by ion-exchange chromatography at 4 °C on a column of SP-Sephadex equilibrated in 0.02 M NaH_2PO_4/6 M urea, *p*H 3.74. The material eluted with a linear gradient of 800 ml of 0.02 M NaH_2PO_4/6 M urea and 800 ml of 0.15 M NaCl/0.02 M NaH_2PO_4/6 M urea, *p*H 3.74. The peptide was located by measuring the absorbance at 275 nm.

After desalting on Bio-Gel P-2 in ammonium bicarbonate and lyophilization, we found that each peptide had the expected amino acid composition by amino acid analysis (Table 1) and eluted as a major peak on C_{18}-reverse-phase HPLC in a linear gradient of 1% triethyl ammonium phosphate, *p*H 3.2, and 2-propanol.

P25 was derived from a purified preparation of HBsAg after solubilization by heating at 100 °C for 2 min in 0.5 M urea/1% SDS/1% 2-mercaptoethanol[19]. The soluble polypeptides were fractionated by cylindrical polyacrylamide gel electrophoresis (PAGE) in 10% gels. (P25 was designated P22 in our previous studies[19,20] based on molecular weight estimations by PAGE.) The SDS-denatured linear P25 polypeptide, which is known to contain 226 amino acid residues, was used as a control for our immunogenicity studies.

The two synthetic peptides (117–137 and 122–137) were incorporated into a series of adjuvant vehicles for immunization of mice. Equal volumes of immunogen and Freund's complete adjuvant (FCA) were emulsified to give a final peptide concentration of 50 μg per 0.4 ml. The alum-absorbed preparations were prepared as described previously[20] with hydrated aluminium potassium sulphate, to give a final suspension containing 50 μg peptide per 0.4 ml. Large multilamellar liposomes were prepared from a mixture of dipalmitoylphosphatidylcholine, cholesterol and dipalmitoylphosphatidic acid in a molar ratio of 2.0 : 1.5 : 0.2 respectively[20]. Dried lipid films were dispersed by vortexing in an aqueous medium at a phospholipid concentration of 20 mM. Liposomes were swollen in solutions containing either 100 μg of peptide per ml or 100 μg of peptide plus 1 mg ml^{-1} muramyl dipeptide (MDP; Sigma). To ensure that comparable doses were given in each case, untrapped antigen was not removed. Previous studies have indicated that ~60% of HBsAg materials were associated with liposomes prepared in these conditions[20]. Final liposome concentrations were adjusted such that each animal received 6 mmol phospholipid and 25 μg peptide with or without 250 μg MDP in a volume of 0.3 ml.

Groups of six female BALB/c mice were immunized intraperitoneally with each of the above preparations. The mice were bled from the tail vein on days 7, 14 and 21. Samples were assayed at a serum dilution of 1 : 4 using a commercial solid-phase radioimmunoassay (Ausab, Abbott, Chicago). Anti-HBs concentrations are expressed as milli-International Units per millilitre (mIU ml^{-1}) based on the international reference preparation of anti-HBs (lot 26.1.77) provided by the International Laboratory for Biological Standards, Central Laboratory of the Netherlands Red Cross Transfusion Service. A computer nonlinear regression program, BMDP3R[21], was used to describe the standard dose–response curve for the WHO international reference preparation from which the potency of each of the samples was obtained[22].

Table 1 Amino acid composition of synthetic peptides

Amino acid	Peptide 122–137	Peptide 117–137 Ser 121
Threonine*	3.75(4)	4.67(5)
Serine*	1.93(2)	3.55(4)
Glutamic acid	1.06(1)	1.06(1)
Proline	0.85(1)	1.92(2)
Glycine	1.00(1)	2.00(2)
Alanine	0.99(1)	1.08(1)
Half cystine†	— (2)	— (2)
Methionine	1.87(2)	1.87(2)
Tyrosine	0.99(1)	0.93(1)
Lysine	0.93(1)	0.92(1)

Analyses were performed on a Beckman model 121 amino acid analyser after hydrolysis *in vacuo* for 24 h at 110 °C in 6 M HCl. The theoretical values are given in parentheses.

* Values are not corrected for destruction during hydrolysis.

† Half cystine was present in the amino acid analysis but was not integrated.

The results given in Table 2 show that (1) approximately 50% of the mice in each group produced detectable levels of antibody 7 days after inoculation of either the synthetic peptides or the P25 polypeptide; (2) the adjuvant vehicle—FCA, alum, liposomes, or liposomes with incorporation of MDP—did not significantly affect the primary antibody response; (3) in several groups the antibody response was greater on day 14, as shown by either the increased anti-HBs concentrations or the number of mice in each group which responded; (4) on day 21, the peak levels of antibody response in most groups of mice decreased; and (5) the antibody response in mice inoculated with purified SDS-denatured P25 was similar to that observed with the synthetic peptides.

When sera from each group of positive mice on days 7, 14 and 21, respectively, were pooled and fractionated by ultracentrifugation in 10–40% (w/v) preformed sucrose gradients[23], IgG antibody was localized in the intermediate fractions and IgM was detected in the rapidly sedimenting fractions. Typical IgM and IgG responses were seen in each group, with one exception: there was no IgG in the group of mice injected with peptide 122–137 emulsified with FCA.

Early work with a plant virus model using tobacco mosaic virus[4,5] and the bacterial virus model using MS-2 coliphage[6] clearly demonstrated the immense potential of preparing immunologically active synthetic peptide analogous to amino acid sequences in an animal virus protein. The present results indicate that amino acid residues localized in the major HBsAg polypeptide, P25, between residues 117 and 137—or more specifically, 122 and 137—contain a determinant that elicits the production of antibody of similar specificity to that produced by immunization with the SDS-denatured linear virus P25 polypeptide[19]. These findings are similar to those reported recently by Lerner *et al.*[9], who prepared a series of synthetic peptides containing segments of the P25 HBsAg polypeptide. Four of their peptides (2–16, 22–35, 48–81 and 95–109) elicited the production of antibody in rabbits which reacted with HBsAg. Synthetic peptides of residues 134–146 and 138–149 (refs 24 and 25 respectively) of P25 have also been prepared. These peptides, which have several amino acids (138–146) in common, were both antigenically active in that each reacted with preparations containing specific anti-HBs activity and they blocked antibody reactivity of sera of animals immunized with intact HBsAg. There have been no reports regarding their immunogenic activity. The amino acid sequences of the six unique immunogenic synthetic peptides included in our study and the above studies have nothing in common except the similarity noted above (residues 138–146) and the overlapping of four carboxyl amino acids of the peptides synthesized in our labora-

Table 2 Anti-HBs concentrations in mice immunized with synthetic HBsAg peptides 117–137 and 122–137

Immunizing preparation	Range of antibody concentrations postinjection (mIU ml^{-1}) Day 7	Day 14	Day 21
117–137–FCA	3.5–8.6(4/6)	3.2–10.3(5/6)	2.6–13.9(5/6)
122–137–FCA	3.6–5.8(3/6)	5.9–11.9(3/6)	17.3–25.9(3/6)
117–137–alum	3.0–7.3(2/6)	2.8–12.6(3/6)	3.4–4.5(2/6)
122–137–alum	2.1–14.5(4/6)	2.5–10.0(3/6)	5.0–6.4(2/6)
117–137–liposomes	2.1–15.4(3/6)	2.0–12.8(4/6)	—
122–137–liposomes	3.6–8.8(3/6)	5.2–12.0(3/6)	5.6–11.8(3/6)
122–137–liposomes +MDP	2.1–23.7(4/6)	2.9–21.0(3/6)	6.8–40.0(2/6)
P25 polypeptide–alum	2.1–17.2(6/6)	2.5–10.5(5/6)	7.1–12.5(2/6)

Only positive antibody values are listed. Numbers in parentheses represent number of mice with an anti-HBs response over total number of mice in each group.

tory with the initial four residues at the amino terminus of the peptide synthesized by Vyas[24]. Thus a number of different amino acid sequences can elicit production of antibody which specifically reacts with HBsAg. It will be essential to immunize susceptible chimpanzees with several of these peptides to ascertain which elicit(s) the production of protective antibody, as we have done with the purified P25 polypeptide[19]. In addition, it will be of interest to learn which sequences contain the cross-reacting 'a' antigenic determinant and which contain the subtype-specific determinants. We selected residues 117–135 because this region is highly hydrophilic, and shows great variation among the published sequences and therefore may contain the subtype-specific determinants[8,24]. It may be found necessary to use more than one of these peptides to produce a highly effective vaccine.

Note that Lerner *et al.*[9] elicited an antibody response to their smaller (14–15 residues) peptides only after repeated inoculation of covalently attached material to a carrier protein. In our study, we observed an antibody response to each peptide (117–137 or 122–137) without using a carrier protein. The greater immunogenicity of our peptides, shown by the detection of antibody activity 7 days after a single injection of peptide, may be because our peptides, consisting of 16 or 21 amino acid residues, contain a determinant which is more immunogenic. Alternatively, disulphide cyclization may be important in locking the secondary structure of a potent immunogen.

The incorporation of various adjuvant vehicles and/or protein carriers should help to increase the immunogenicity of these synthetic peptides. This approach may offer advantages in the production of a vaccine against the hepatitis B virus, since the relative immunogenicity of the HBsAg-derived polypeptides is considerably less than that observed for intact HBsAg 22-nm particles[19].

New Epstein–Barr virus variants from cellular subclones of P3J-HR-1 Burkitt lymphoma

L. Heston, M. Rabson, N. Brown & G. Miller*

Departments of Pediatrics and Epidemiology and Public Health,
Yale University School of Medicine, New Haven,
Connecticut 06510, USA

The P3J-HR-1 (HR-1) line contains unique Epstein–Barr viruses (EBVs) which fail to immortalize lymphocytes or to induce lymphomas[1–4]. Virus from Jijoye, the parent of the HR-1 clone, retains lymphocyte-immortalizing ability[5,6]. Because the HR-1 virus population is a mixture, it has not been possible to identify conclusively the genomic alterations responsible for the nontransforming phenotype[7]. Submolar fragments produced by restriction enzyme digestion and the variety of patterns found after partial denaturation are evidence for heterogeneity in HR-1 virion DNA[8,9]. To determine whether every cell carried this virus mixture, or whether the line consisted of cells carrying different variants, we separated the mixture by cell subcloning into new variants, which are found to be distinct from parental HR-1 virus both biologically and in genome structure.

HR-1 cells were cloned in agarose with an efficiency of 37% (refs 10, 11). The copy number of EBV genomes in 29 subclones derived in two experiments (FF452, GG68) was determined by nucleic acid spot hybridization[12] (Fig. 1*a*). The parental HR-1 line contained ~300 genomes per cell; all subclones had lower copy numbers, between 3 and 22 genomes per cell. Following treatment with 12-*O*-tetradecanoyl-phorbol-13-acetate (TPA) which induces viral DNA synthesis in the HR-1 line[13], there was an increase, to a minimum of 200 EBV DNA copies per cell, in each of the clones (Fig. 1*b*). However the response to TPA was exaggerated in five clones (GG68 nos 5, 11, 13, 17 and 19) which after treatment contained 3,000–6,000 EBV DNA copies per cell. These clones are called 'superinducible'. The same five clones released large amounts of viral DNA (4×10^7–4×10^8 genomes per ml) into the culture supernatants after treatment with TPA (Fig. 1*c*). Differences in content of viral DNA correlated with levels of viral capsid antigen (VCA). In all clones antigen expression (≤1%) was markedly below the 10% antigen-positive cells found in the HR-1 line. Following treatment with TPA, 50–80% of cells in the five superinducible clones became antigen positive; only slight enhancement of VCA expression was seen in the rest of the clones.

These data indicated heterogeneity among subclones in the extent of viral replication. None of the 29 clones spontaneously released EBV in amounts comparable with the parental line. Cloning of the spontaneous producer may require less stringent conditions. Spontaneous viral particle synthesis in the HR-1 line may involve interaction between different viruses in the line. The superinducible clones will be useful in further studies: as some yield 10–20 times more viral DNA than the parental HR-1 line, they may help in analysis of genome structure and repli-

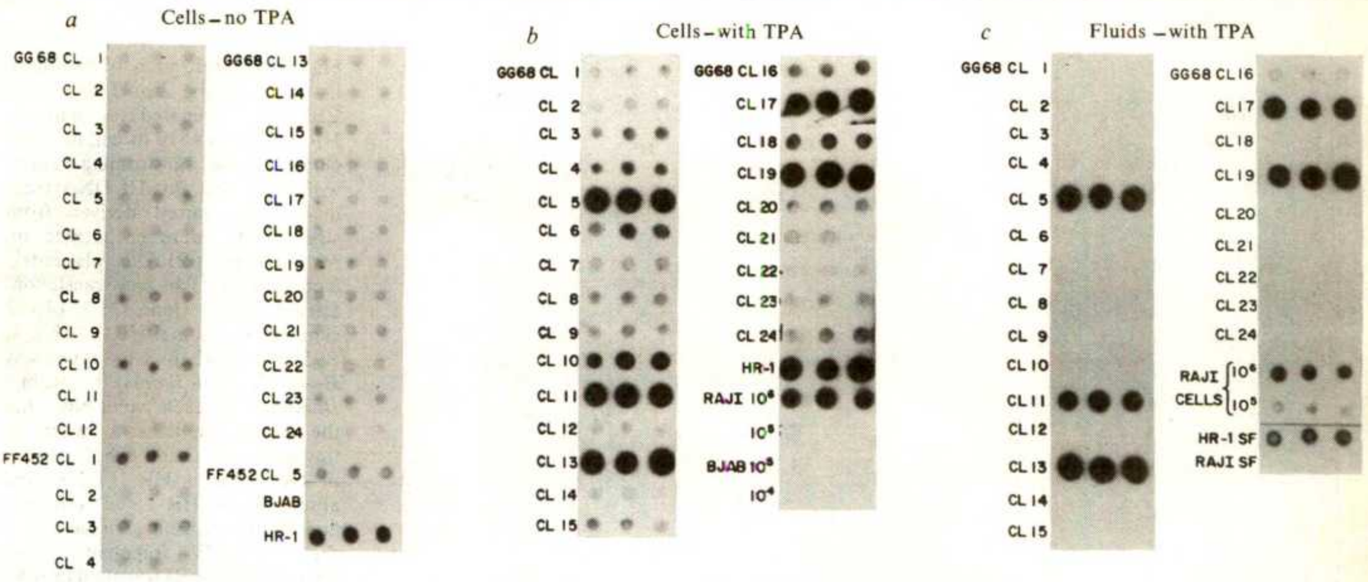

Fig. 1 Estimation of EBV DNA content of the HR-1 line and its subclones by nucleic acid spot hybridization. Each filter was probed with $1\text{-}5\times10^6$ c.p.m. of nick-translated ^{32}P-labelled EBV DNA prepared with 300 ng of HR-1 DNA. *a*, Genome content of 29 subclones and the HR-1 parent without TPA treatment. Each spot contains 10^5 cells collected 6 days after subculture. BJAB cells (EBV genome negative) serve as negative control. Autoradiograph exposed for 18 h. *b*, Genome content of 24 subclones and the HR-1 parent with TPA treatment. Each spot contains 10^5 cells collected 6 days after subculture with 20 ng ml^{-1} TPA. The positive control was 10^6 and 10^5 Raji cells; the negative control was 10^5 and 10^4 BJAB cells. Neither BJAB nor Raji was treated with TPA. *c*, Genome content of supernatant fluids from 24 subclones and the HR-1 parent collected 14 days after subculture in the presence of 20 ng ml^{-1} TPA. 10^6 and 10^5 Raji cells (no TPA treatment) served as positive control. Raji supernatant fluid (SF) which does not contain virions was negative control. High levels of hybridization seen with fluids in *c* are seen in *b* with intracellular EBV DNA from the same cell clones. Autoradiograph exposure in *b* and *c* was 4 h.

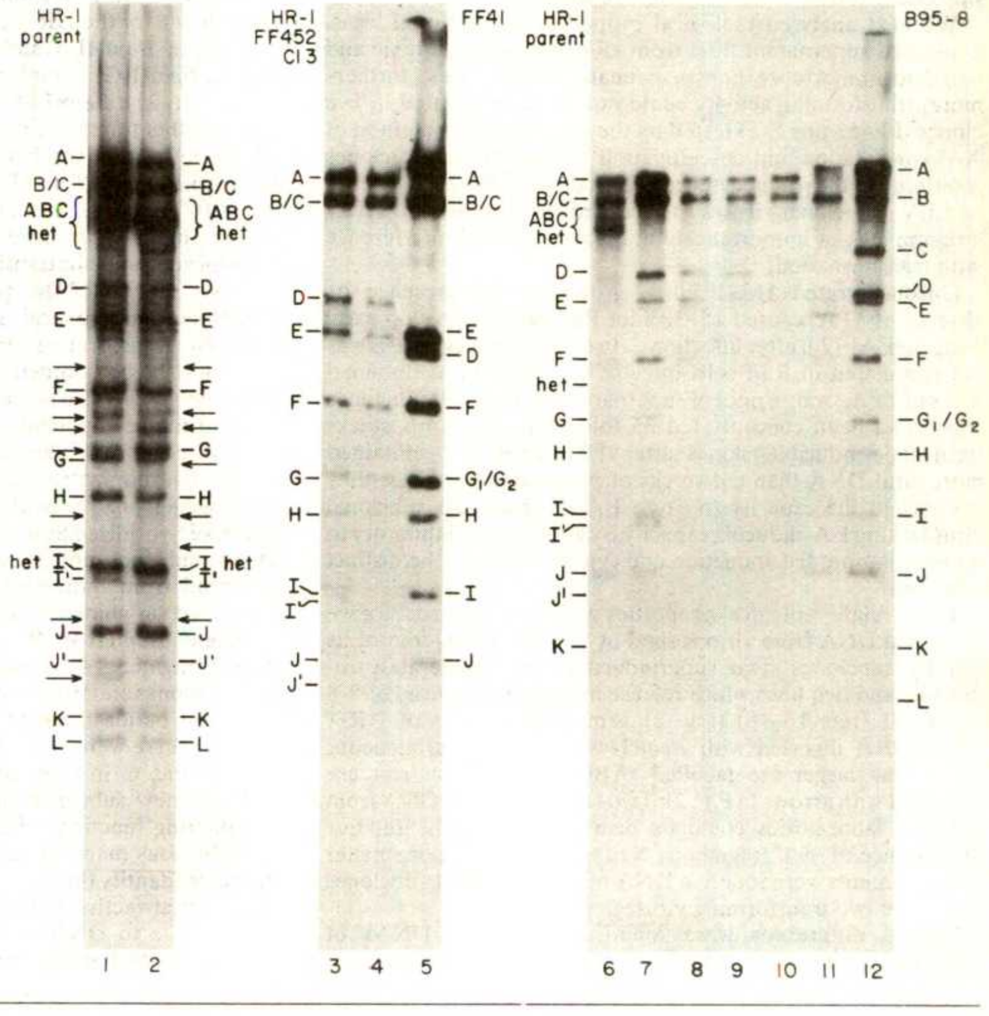

Fig. 2 *Eco*RI digestion of EBV DNA prepared from virions. DNA was extracted from virions shed into 20 l of culture supernatants 14 days after addition of 20 ng ml^{-1} TPA. Lanes 1–5 contained 600 ng of EBV DNA; lanes 6–12 50 ng of DNA. Each panel is an autoradiograph of a Southern blot hybridized with 10^7 c.p.m. of nick-translated ^{32}P-labelled HR-1 DNA. Lane 1, HR-1 parental (LS strain from M. Nonoyama); 2, HR-1 parent (laboratory strain); 3, 4, FF452, clone 3, a 'moderately inducible' HR-1 clone; 5, FF41, a transforming EBV originally from saliva[16]; 6, HR-1 parent (LS strain); 7, GG68 clone 5 'superinducible'; 8, GG68 clone 13 'superinducible'; 9, FF452 clone 3 (this DNA was prepared from the clone passaged for 10 months after preparation of the DNA shown in lanes 3 and 4); 10, FF452 clone 5 moderately inducible; 11, FF41; 12, B95-8, a transforming EBV originally from blood. Note that the bands 'ABC het' and other 'het' bands, indicated by an arrow in the DNA of the HR-1 parent, are not seen in the DNA prepared from the cell clones, and that the *Eco*RI A fragment is smaller in the DNA of the parental HR-1 and all of its subclones than in the DNA of the transforming B95-8 and FF41 strains.

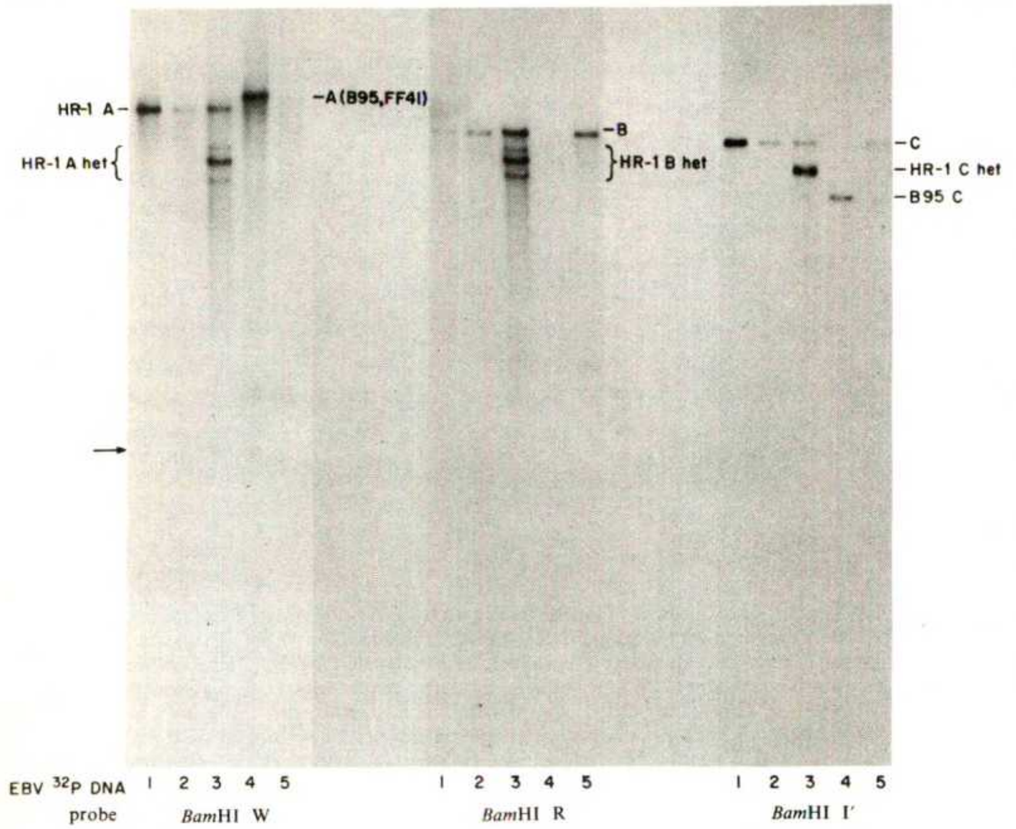

Fig. 3 Hybridization of Southern blots, containing *Eco*RI digests of EBV DNA, prepared from parental HR-1 DNA, two of its cellular subclones and two transforming viruses, with individual *Bam*HI DNA fragments. The latter, derived from strain FF41, were propagated on recombinant pBR322 plasmids[16] labelled with ^{32}P by nick translation. Lane 1, GG68 clone 13; 2, FF452 clone 3; 3, parental HR-1 (lab.); 4, B95-8; 5, FF41. In *a* the probe was *Bam*HI W, in *b* *Bam*HI R, and in *c* *Bam*HI I′. In each panel note that the probe identifies a group of fragments (A, B and C het) present in the parental HR-1 DNA and absent in the HR-1 cell subclones and the transforming viruses. In *a* the *Bam*HI W fragment faintly identifies an *Eco*RI fragment (arrow) of approximate molecular weight 2.4×10^6 in all strains. The genome location of this fragment is not known. *c* Shows the previously described[16,22] deletion in the *Eco*RI C fragment of B95-8.

cation. Studies of transcription of the EBV genome in the absence of productive infection and after TPA induction should ultimately clarify mechanisms by which the cell–virus relationship changes from latency to virus production.

We next analysed biological properties of subclonal virus. Undiluted supernatant fluid from all clones was cytotoxic and failed to immortalize human neonatal lymphocytes; furthermore, transforming activity could not be demonstrated in five clones (FF452 nos 1–5) tested by the more sensitive method of X-ray irradiation and co-cultivation[14]. Virus from two clones interfered with lymphocyte transformation by the B95-8 strain of EBV. Subclonal viruses thus resembled the parental HR-1 strain in lack of immortalization, cytotoxicity and interference with transformation.

Unconcentrated HR-1 virus, grown in the presence or absence of TPA, caused 15–30% of Raji cells to develop early antigen (EA) 72 h after infection[15]. In contrast EA synthesis was not stimulated in Raji cells infected by clonal virus obtained without TPA, or by a pool of supernatants from all 29 subclones which had been concentrated 35-fold. Although virus stocks from superinducible clones after TPA treatment contained more viral DNA than did stocks of parental HR-1 virus, they still lacked the capacity to cause EA synthesis. As subclonal virus lacking EA-inducing capacity is cytotoxic and inhibitory to transformation, EA induction and cytotoxicity must be distinct functions.

To correlate biological properties with genome structure we examined DNA from virions shed by the HR-1 line, four of its cellular subclones (two superinducible, two moderately inducible) and two lines which release immortalizing virus B95-8 and FF41 (refs 16–18) (Fig. 2). Among fragments of HR-1 virion DNA digested with *Eco*RI were many heterogeneous bands (the larger are labelled 'ABC het' and the rest are indicated with arrows in Fig. 2). Two stocks of HR-1 DNA from different laboratories could be distinguished by the relative prominence of 'het' fragments. Neither 'ABC het' nor smaller 'het' fragments were found in DNA of the four HR-1 subclones nor in the two transforming viruses.

Several differences were found between the DNAs of nontransforming viruses (parental HR-1 and its subclones) and the two transforming strains (Fig. 2). These will be described fully elsewhere (M.R. and G.M., in preparation) but briefly: *Eco*RI A is consistently larger in both transforming viruses than in the four nontransforming HR-1 subclones, as has previously been shown for the HR-1 parent[19–21], due to a 1.95 megadalton deletion of *Bam*HI Y and part of *Bam*HI H. In HR-1 and its clones, *Eco*RI G_2 is replaced by two new fragments, *Eco*RI I′ and J′ (ref. 21). *Eco*RI D, the right terminus, is larger in HR-1 than in either transforming virus. In the HR-1 clones there is loss of one restriction site between *Bam*HI B and G and another between *Bam*HI W′ and I′. There is also a deletion in *Bam*HI L ($\sim 5 \times 10^4$ daltons) and an insertion in *Bam*HI P ($\sim 6 \times 10^4$ daltons) in the nontransforming virus. Thus differences between transforming and nontransforming variants are scattered over at least six regions of the genome; however there is extensive homology and general similarity in genome organization between transforming and nontransforming EBVs[20,21]. It remains to be determined which lesions found in the genomes of HR-1 clones are also present in the Jijoye line which retains the transforming component.

Absence of ABC het and smaller het fragments from the *Eco*RI digestion pattern of subclonal viral DNA suggested that heterogeneity had been eliminated by cell cloning. To prove this point we hybridized Southern blots, containing *Eco*RI digests of HR-1, subclone and transforming virion DNA, with probes prepared from individual *Bam*HI fragments of EBV DNA contained on chimaeric plasmids[16] (Fig. 3). The probes were fragments *Bam*HI W, R and I′ which are found, respectively, in *Eco*RI fragments A, B and C[17,18]. Virion DNA from two HR-1 cell subclones and from two transforming viruses each contained only one major fragment with homology to the probes. In contrast there were at least three or four size variants of *Eco*RI 'A', 'B' and 'C' in parental HR-1 DNA.

These new subclonal mutant EB viruses will be useful in deciphering functions of the EBV genome. They could allow unambiguous mapping of the transforming region and should also help identify the genes responsible for EA induction in Raji cells. An attractive hypothesis is that EA induction by HR-1 virus is due to DNA represented by one or more ABC het fragments which were eliminated by cellular cloning.

Evidence from mtDNA sequences that common laboratory strains of inbred mice are descended from a single female

Stephen D. Ferris*†, Richard D. Sage‡ & Allan C. Wilson*

* Department of Biochemistry and ‡ Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA

The rapid evolution[1] and maternal mode of inheritance[2] of mitochondrial DNA (mtDNA) make it a valuable marker for individuals related by descent from the same female[3]. We report here a study of wild and inbred mice which illustrates this point. We have examined mouse mtDNA from various locales in the Northern Hemisphere using restriction enzymes that cut the molecule at an average of 150 sites and find a high level of restriction-site polymorphism in wild mice but no variation among the 'old' inbred strains. This result is surprising because the nuclear genomes of these strains are known to differ greatly from one another[4]. The old inbred type of mtDNA occurs rarely in wild mice and differs from other types in the wild by an average of 100 nucleotide substitutions. In possible contradiction of published breeding records, these findings indicate that only one female lineage contributed to the formation of all the old inbred lines. In addition, our study of new inbred strains provides genetic markers that will be useful in mouse developmental and cell biology.

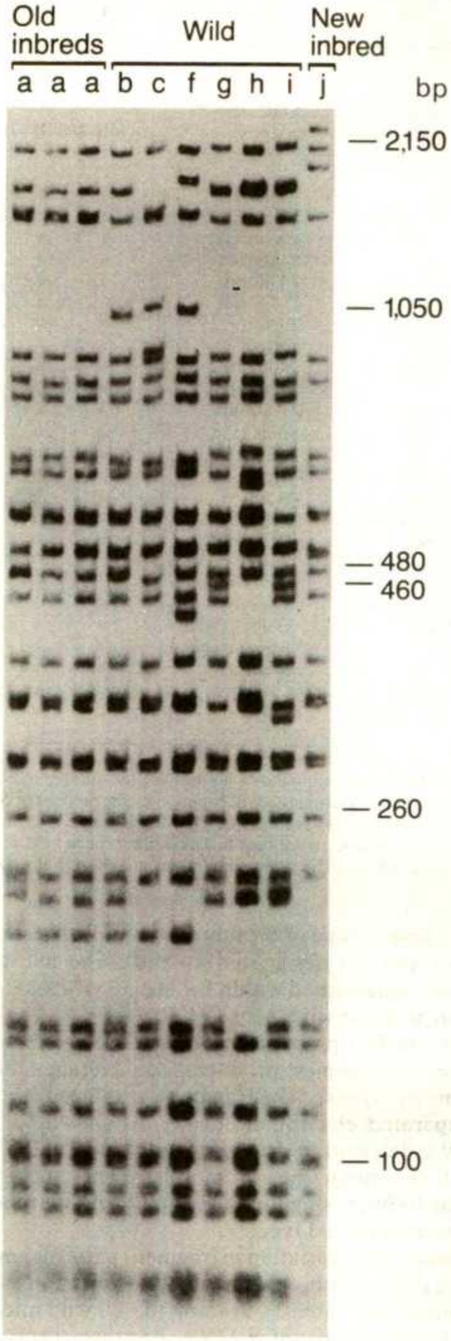

Fig. 1 Electrophoresis of 10 mouse mtDNAs. After purifying mtDNA from tissues of single mice and digesting it with *Mbo*I, the fragments were labelled and separated by electrophoresis as described elsewhere[27]. Lanes 1–3 show the identity of fragment patterns for three old inbred mice, C57BL, BALB/c and SWR. Lanes 4–9 show variation among six wild mice whose fragment patterns correspond to those indicated by small letters in Table 1. The animals are from diverse geographical areas: Maryland (USA), Egypt, Switzerland, Morocco, Yugoslavia and Denmark. Lane 10 shows the fragment pattern of a new inbred strain, SF/Cam, founded from a wild mouse in California. The sizes in base pairs (bp) of the size standards (PM2 phage DNA digested with *Hin*dIII) are indicated on the right.

Thirty-four samples of *Mus domesticus* mtDNA were obtained from 14 inbred strains and 20 wild mice collected in North America, western Europe, North Africa and the Near East. (The name *Mus domesticus* has been coined for a newly recognized species that includes the common laboratory strains and the wild mice populations formerly classified as the subspecies *M. musculus domesticus*, *M. musculus brevirostris* and *M. musculus praetextus*[5]. This species differs substantially from *M. musculus*, the house mouse of eastern Europe (formerly known as the subspecies *M. musculus musculus*), in anatomy, behaviour and protein structure[5,6], as well as in mtDNA structure[7]. Moreover, the two species are almost completely isolated from each other genetically due to geographical and multiple sterility barriers[8].) The sources of the 34 mtDNA samples are

Point mutations were estimated by multiplying the number of base pairs (16,295) in mouse mtDNA[10] by the number of base substitutions per base pair (calculated from the fraction of restriction fragments in common by the method of Nei and Li[9]). Old inbreds are BALB/cJ, C57BL/6J, C58/J, DBA/2N, SWR/J, AU/SsJ, C3H, PL/J and AKR/Cu. A cell line (LA9) represented the C3H strain.

* The Danish populations are classified as another species (*M. musculus*) on the basis of morphological and protein evidence[5], but possess *M. domesticus* DNA, probably owing to introgression[7]. The three populations are close to the zone of contact with *M. domesticus*[26].

given in Table 1. Nine of the inbred strains were established over 40 yr ago and are designated as 'old'. The five other inbred strains were established within the last 30 yr[4] from female house mice caught in the wild.

Highly purified preparations of mtDNA were digested with 11 restriction enzymes, producing, on average, 150 restriction fragments per mouse. The fragments produced by each enzyme were separated electrophoretically, as shown for 10 mice in Fig. 1. We detected 58 fragment patterns; Table 1 shows their distribution among the 34 samples. The mice are ordered according to increasing number of pattern differences from the most common inbred type.

We found much variation in fragment patterns among the wild mice and the new inbred strains but no variation among the old inbred mice (see Table 1). Among the 20 wild mice studied we found 15 distinct types of mtDNA; one type corresponds to that found in the old inbred mice. It was found only twice, once in California and once in Denmark. A more recent survey using the enzymes *Hin*fI and *Mbo*I revealed six more mtDNA types in 36 additional wild mice, none of which had the old inbred type (R.D.S., S.D.F. and A.C.W., unpublished observations). The frequency of occurrence of the old inbred type is therefore 0.04 in the wild mice tested.

The extent to which these DNAs differ in nucleotide sequence from the old inbred type may be estimated from the number of fragments they have in common[9]. These estimates are based on the assumption that the differences in fragment pattern are due exclusively to base substitution. There is evidence in support of the assumption that mouse mtDNA evolves almost exclusively by base substitution[7,10]. The old inbred type is estimated to differ from other types of *M. domesticus* mtDNA by 12–230 base substitutions (Table 1). The mean difference of 137 substitutions corresponds to almost a 1% sequence difference, which is typical of the mtDNA diversity found in other mammal species[11–15]. Our result deserves emphasis because earlier surveys using fewer restriction sites[16,17] and fewer mice[18] seemed to indicate a low level of mtDNA polymorphism in wild mice.

The high level of variation in mtDNA of wild *M. domesticus* is consistent with electrophoretic[19,20] and immunological[21] evidence for a high level of nuclear gene variation in this species. However, the absence of mtDNA variation among the old inbred strains contrasts sharply with the presence of large nuclear differences in these strains[4]. To account for this, we suggest that a single female lineage founded all the old inbred strains, the nuclear diversity among these strains being due mainly to the mating of this lineage with diverse males. This hypothesis agrees with the recorded origins of inbred strains of laboratory mice[4,22]. The nine old inbred strains listed in Table 1 are thought to stem from a minimum of five different mothers which founded the primary strains as follows: DBA (in 1909 from a random stock at the Bussey Institute, Cambridge, Massachusetts), BALB/c (in 1913 from an Ohio pet dealer), SWR (before 1920 from a random stock at the Pasteur Institute, Paris), PL (before 1922 from a New Jersey pet dealer), and C57-C58 (in 1921 from a Massachusetts pet mouse dealer). If these five females had been picked at random from the wild, the probability of them all having the old inbred type of mtDNA seems, from our survey, to be extremely low ($\sim 10^{-7}$). It is likely, however, that all were from the pet mouse trade[23,24], in which case the old inbred type of mtDNA could already have been present at high frequency. A high frequency could be the result of a chance event when the pet mouse population was very small. Such an event could have occurred as long ago as 3,200 BP, when the white mouse cult began in the temple of Apollo Smintheus[23].

Selection, rather than chance fixation, could also explain why all the old inbred strains contain the same type of mtDNA and thus appear to be descended from one female. A high frequency of the old inbred type of mtDNA could be attributed to selection for mice bearing this DNA if they were better suited for survival in the pet mouse trade. Selection could act in a second way, by this DNA type giving mice a better chance of surviving laboratory inbreeding. If this were the case, the five primary strains could represent the most successful of many attempts to establish inbred lines. As early publications do not record failures to establish inbred strains, it is uncertain whether such selection need be invoked. However, a selectionist explanation does not account convincingly for the ease with which wild mice give rise to new inbred strains possessing other types of mtDNA, for example, PAC, IS/Cam and SF/Cam (see Table 1). Furthermore, our finding of the SF/Cam type of mtDNA in wild mice of the San Francisco area (R.D.S., S.D.F. and A.C.W., unpublished observations) is evidence against the argument that this inbred type evolved *de novo* in laboratory conditions. Given that an explanation involving chance fixation could account for the data, we think it unnecessary to invoke an additional factor, such as selection.

Contamination of one strain by another also ought to be considered in relation to the hypothesis that all the old inbred strains trace back to one female in the pet mouse population. The five primary strains could have been crossed soon after they were established in the laboratory, which would imply that published reports are inaccurate in describing the early breeding programmes. It is likely that such a mix-up could have occurred between 1919 and 1921 when Strong and Little had the founding stocks of three of the critical strains (DBA, BALB/c and C57-C58)[4,22]. Any inter-strain matings at this time, while the DBA strain was at a low ebb, might reasonably link this strain with at least one of the others.

The reason for suggesting this possibility is that the inadvertent mixing of inbred strains may be a common phenomenon even today. There are four recent cases of apparent contamination. (1) Festing[25] has described contamination of the C3H and AKR strains, based on nuclear evidence. (2) There is the case of the new inbred strain MOR, founded from wild mice in Ohio[4], whose black coat colour is evidence for the presence of nuclear genes from an old inbred strain (probably C57BL/6) in the MOR genome, as this coat colour is rare among wild house mice in North America. Consistent with the idea of contamination, MOR has the old inbred type of mtDNA (see Table 1). (3) Two new inbred strains (SF/Cam and SK/Cam), although founded by wild females in California and England, respectively, have the same rare type of mtDNA (see Table 1). The SK strain examined has probably been mixed with the SF strain because the mtDNA fragment patterns observed for SK/Cam/Ei differ greatly from those reported by Yonekawa *et al.*[17] who used another source of SK/Cam mice. In addition, the SK/Cam/Ei strain carries several protein variants that are diagnostic of the SF/Cam strain (E. Eicher, personal communication). (4) The most spectacular example is provided by two non-inbred strains of the Japanese house mouse, *M. molossinus*[5,6]. One strain, maintained by Potter at NIH, retains the *molossinus* type of mtDNA, which differs by almost 4 per cent in sequence from that of *M. domesticus*[7]. The other strain, KL/oci, is derived from Potter's strain and has been propagated in a series of other laboratories for >10 yr; KL/oci now has the old inbred type of mtDNA, while retaining proteins characteristic of *M. molossinus*. As extensive sampling of wild mice in Japan revealed no *domesticus*-like types of mtDNA[16], this could be the clearest case of laboratory contamination of a strain by *domesticus* mice bearing the old inbred type of mtDNA.

Thus, we propose that the old inbred mouse strains could be descendants of a single female that lived as recently as 1920, in which case she or her daughters cross-bred with the five primary strains of inbred mice. Alternatively, she could have been a member of the pet mouse population possibly as long ago as 3,200 BP. Besides contributing to knowledge of the genealogy of old inbred mice, our mtDNA study draws attention to cases of contamination of other stocks of laboratory mice and provides new genetic markers for use in cell and developmental biology, for example, markers for cells in chimaeras.

This work was supported by the Miller Institute, University of California (S.D.F.), NSF grants DEB 72-02545 (to R.D.S.) and DEB 78-02841 (to A.C.W.) and NIH grant 5 RO1 GM21509-07 (to A.C.W.). We thank R. Cann and E. Zimmer for discussion, V. Chapman, M. Ferris, M. Lieberman, T. Nakada and M. Potter for providing mice, and W. Brown for LA9 mtDNA.

Recent divergence from a common ancestor of human IFN-α genes

Takashi Miyata & Hidenori Hayashida

Department of Biology, Faculty of Science, Kyushu University, Fukuoka 812, Japan

The two major classes of human type I interferons, leukocyte or α-interferon (IFN-α) and fibroblast or β-interferon (IFN-β) are antigenically distinct and encoded by separate structural genes[1]. Recently, genomic hybridization experiments have demonstrated the presence of ~10 or more distinct human IFN-α (Hu IFN-α) genes which code for a family of homologous yet distinct proteins[2,3], and 8 of these have been identified and sequenced[3]. In contrast, no evidence has been found for multiple Hu IFN-β genes[3], although heterogeneity of Hu IFN-β mRNA has been observed[4,5]. The coding sequences of Hu IFN-α and IFN-β genes show weak but appreciable homology, indicating that they were derived from a common ancestor at a remote time[6], whereas Hu IFN-α_1 (a member of class D) and Hu IFN-α_2 (a member of class A) diverged quite recently (~22 Myr ago)[7]. We report here that all eight known IFN-α genes diverged from a common ancestor quite recently, at most ~26 Myr ago. As mammalian divergence is known to have occurred ~75 Myr ago[8], this suggests that the IFN-α multigene family in primates is distinct in organization from that of other mammals. We provide evidence for a much lower rate of evolution for IFN-α G than for other α-interferons, and a rapid evolution of IFN-α E pseudogene similar to that of other pseudogenes[9–11]. A possible evolutionary origin of size heterogeneity in the 3′-noncoding region of IFN-α mRNAs is also discussed.

A single base change in a codon results in either replacement of the encoded amino acid (replacement substitution) or the appearance of a synonymous codon (synonymous substitution). We shall refer to a site where a single base change leads to synonymous (replacement) substitution as a synonymous (replacement) site[12]. At each position in the codon, three

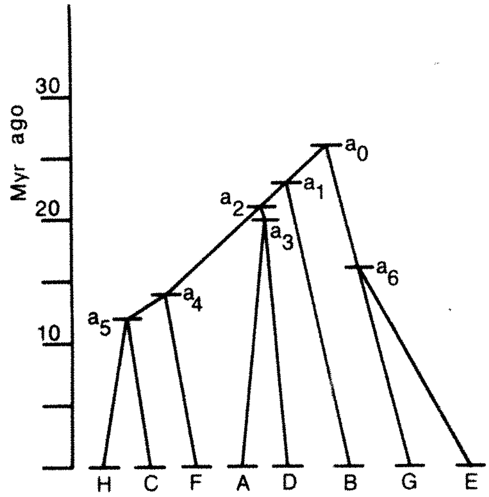

Fig. 1 Evolutionary relationships of eight distinct Hu IFN-α genes. The tree was constructed as follows. Based on the K_S values of pairs of seven functional genes, we first constructed a dendrogram using the clustering method[32]. This method gives an average value of K_S ($\bar{K}_S$) for all pairs of genes between the groups which are derived from a particular node. For example, $\bar{K}_S$ for pairs between groups (H, C) and group (F), which are joined to each other at node a_4, is estimated as 0.127 and that for pairs between groups (H, C, F) and (A, D), which are joined at node a_2, is 0.190, and so on. From $\bar{K}_S$, we have estimated the divergence times of nodes a_0–a_5 as described in the text. The estimated times are 26, 23, 21, 20, 14 and 12 Myr for a_0–a_5, respectively. The date t_6 corresponding to node a_6 was also estimated from K_S as follows. Let O be the common ancestor of G and E; the average difference of synonymous sites between O and G is 0.075 as described in the text. Correcting for multiple hits using $K^c = -(3/4)\ln(1-(4/3)K)$[16,17], and dividing the corrected value by $v_S (= 5.1\times10^{-9}$ per site per yr), the rate of change at the synonymous sites, gives $t_6 = 16$ Myr.

different single base changes are possible, of which a fraction (f) results in synonymous substitutions, while the remainder $1-f$ leads to replacement substitutions. In the codon UUU, for example, the first two positions are replacement sites ($f=0$) whereas for the last position one-third of changes correspond to synonymous sites ($f=1/3$). Thus the codon UUU contains $0.333(=0+0+1/3)$ synonymous sites and $2.667(=1+1+2/3)$ replacement sites.

Previously, on the basis of this definition, we presented a method for estimating mucleotide differences per site at synonymous sites (K_S) and at replacement sites (K_A) by comparing homologous nucleotide sequences of coding regions[12]. Applying the method to several mammalian genes, we showed that the rate of synonymous substitution, v_S, is greater than that of replacement substitution and, more important, is approximately constant among different genes[13]. This is in sharp contrast to the rate of protein evolution, which varies for different proteins[8,14,15]. Thus, because the rate of synonymous substitution for different genes is uniform, it can be used as a 'clock' to show the true evolutionary branching orders of genes in a multigene family, even when the encoded proteins evolve at different rates. For example, if two duplicated genes are compared and the K_S determined, then the time (t) since divergence of the two genes can be estimated from the formula[16,17]

$$t = -(3/4)\ln(1-(4/3)K_S)/2v_S \tag{1}$$

using the value of v_S previously calculated as 5.1×10^{-9} per site per yr[13]. Here, K_S is corrected for the effect of multiple hits (a computer simulation showed that this formula is suited for correcting K_S and K_A at least within a short evolutionary period [unpublished results]). Recently, we have confirmed the uniformity of the synonymous substitution rate by comparing many more sequences of different mammalian genes[18].

From pairwise comparisons of coding sequences of eight distinct Hu IFN-α genes, we have calculated K_S and K_A for each pair of genes (Table 1). Based on the K_S values, phylogenetic relationships among the IFN-α genes, and IFN-α pseudogene, were determined (Fig. 1). The seven functional IFN-α genes were classified into three groups according to the divergence times from ancestors. Surprisingly, all eight Hu IFN-α genes seem to have diverged from a common ancestor quite recently, at most ~26 Myr ago. As mammalian divergence is known to have occurred ~75 Myr ago[8], this result suggests that they have different organization compared with other mammals. This notion is of particular interest in relation to the observation that interferons are often species specific[19]. To test this, IFN-α gene sequences have been compared for different species. A pairwise comparison of the N-terminal 20-amino acid sequence of a mouse IFN-α[20] with the six human α-interferons (A–D, F, H) showed that the latter are much more homologous to each other than to the mouse IFN-α. In fact, of 20 amino acid sites compared, on average 3.8 ± 1.9 sites differ within the six human α-interferons, whereas there are 8.8 ± 1.7 site differences between human and mouse α-interferons. Although the comparison was limited to the N-terminal region, this result in part supports the above argument.

The K_A matrix for seven functional IFN-α genes gives almost the same phylogenetic relationship among the genes as that shown in Fig. 1, except for the IFN-α G gene line. Unusually small K_A values were found for gene pairs with the G gene as a partner. Ratios of K_A/K_S for these pairs are lower (0.26 on average) than those for other pairs (0.43), suggesting that the replacement sites of IFN-α G gene have a low evolutionary rate (note that the ratio for a given pair is insensitive to the divergence time of two compared sequences). Alternatively, the IFN-α G gene may have arisen quite recently, as predicted by K_A values, and accumulated more base substitutions at the synonymous sites than other genes. To resolve this, we compared further the sequences of the 3′-noncoding region (which corresponds to a region upstream of the poly(A) site of the A gene in the aligned sequence[3]) for the seven functional

Fig. 2 Alignment of the untranscribed 3′-flanking (3′UF) sequence of IFN-α_1 (ref. 2) (a member of class D)[3] and the terminal sequences of five IFN-α mRNAs[3]. The sequence immediately after the poly(A) site of IFN-α_1 is indicated by lower case letters. Bases that are identical between the IFN-α_1 and B are indicated by dots. The hexanucleotides AATAAA and ATTAAA are underlined. Broken lines indicate gaps introduced to obtain maximum homology.

Table 1 Sequence differences at synonymous sites (K_S) and at replacement sites (K_A) from pairwise comparison of eight distinct Hu IFN-α gene sequences

			K_S							
			I			II			III	
		IFN-α	C	F	H	A	B	D	G	E

K_S (upper half) and K_A (lower half) were calculated by a method described elsewhere[12]. Only the sequence encoding the C-terminal 133 amino acids is available for the coding region of the IFN-α G gene[3]. To make equivalent comparisons of all the gene sequences, only differences in this region were considered for all the genes (even when coding sequences corresponding to mature IFN-α are compared, similar values are obtained for K_S and K_A, although in this case, only the fragment-length sequence is considered in pairwise comparisons involving IFN-α G). IFN-α B gene contains frameshift mutations at codons 98 and 101 (ref. 3), thus this segment was excluded from the comparisons. IFN-α E gene contains a single base insertion[3]; to restore the original reading frame, this insertion was deleted. Functional genes were classified into three groups, I(IFN-α C, F and H), II(A, B and D) and III(G), as the ancestral nodes leading to the present-day genes within each group appear to be in clusters with respect to the divergence time (see Fig. 1).

genes, and obtained a phylogenetic tree (data not shown) essentially identical to that shown in Fig. 1. In addition, the extent of sequence divergence in the noncoding region was similar to K_S in value. These results support the former interpretation.

Using the deduced divergence time, we estimated the rate of evolution at the replacement sites of the G gene (v'_A) and that of other functional genes (v_A). For all pairs between groups which were derived from a particular node in Fig. 1, except for a_0 and a_6, the K_A values of the pairs were averaged ($\bar{K}_A$) and then the v_A calculated as $v_A = \bar{K}^c_A/2t$, where t is the divergence time corresponding to the node and $K^c = -(3/4)\ln[1-(4/3)K]$. For example, two groups, the one containing H and C and the other containing F, were derived from node a_4, and thus the pair F–H and F–C have the same divergence time ($t = 14$ Myr) corresponding to the node. The average difference $\bar{K}_A$ is 0.062, which gives $v_A = 2.3\times10^{-9}$ per site per yr, and so on (Table 1). The average value of v_A, estimated for the five different nodes, is 2.1×10^{-9} per site per yr, which, when converted into rate (v_{aa}) defined at the protein level, corresponds to $\sim5.0\times10^{-9}$ per residue per yr (as the number of replacement sites per codon was estimated to be $\sim$2.4 on average, $v_{aa} = 2.4\ v_A$). This rate is high, almost comparable with that of immunoglobulin[8]. To estimate v'_A, two different speeds of evolution were assumed: one (v'_A) in the line from a_0 to G in Fig. 1; the other (v_A) in the line from a_0 to functional genes (X) other than the G gene. This gives the equation

$$v_A t_0 + v'_A t_0 = K^c_A(\mathrm{G{-}X}) \qquad (2)$$

where t_0 is the date of node a_0 and K(G–X) is the sequence difference between G and X. Solving this for each functional gene and averaging the resulting values of v'_A, we obtain $v'_A = 0.17\times10^{-9}$ per site per yr or $v'_{aa} = 0.41\times10^{-9}$ per residue per yr, which is similar to the rate for insulin, a slowly evolving molecule[8]. It is remarkable that the IFN-α G gene, a direct descendant of the common ancestor of all the eight distinct classes, accumulates far fewer base substitutions at the replacement sites than other IFN-α genes, at a rate of about one-tenth that of the other genes, suggesting the presence of strong selective pressure depending on the unique function of the encoded protein.

The Hu IFN-α multigene family contains a pseudogene (IFN-α E) which shows close sequence homology to the IFN-α G gene, suggesting that it was derived from the G gene during evolution. This represents the first evidence of a pseudogene transcribed into mRNA[3]. Thus it is interesting to determine whether or not the IFN-α E gene shows strong sequence divergence similar to that of other pseudogenes[21–26]. We have calculated differences between gene sequences from their joint node (a_6 of Fig. 1). Designating 'O' for node a_6 and X for any one of IFN-α A, B, C, D, F and H genes, we have a set of equations: $K(\mathrm{X{-}G}) = K(\mathrm{O{-}X}) + K(\mathrm{O{-}G})$, $K(\mathrm{X{-}E}) = K(\mathrm{O{-}X}) + K(\mathrm{O{-}E})$ and $K(\mathrm{G{-}E}) = K(\mathrm{O{-}G}) + K(\mathrm{O{-}E})$, where K(O–G), for example, represents the sequence difference between O and G. Solving this, we obtain $K(\mathrm{O{-}G}) = [K(\mathrm{X{-}G}) + K(\mathrm{G{-}E}) - K(\mathrm{X{-}E})]/2$, $K(\mathrm{O{-}E}) = [K(\mathrm{X{-}E}) + K(\mathrm{G{-}E}) - K(\mathrm{X{-}G})]/2$ and $K(\mathrm{O{-}X}) = [K(\mathrm{X{-}G}) + K(\mathrm{X{-}E}) - K(\mathrm{G{-}E})]/2$. Using the K_S values in Table 1, we calculated the three differences for each X. The mean values (±s.e.) of the three differences were $K_S(\mathrm{O{-}G}) = 0.075(\pm0.031)$, $K_S(\mathrm{O{-}E}) = 0.126(\pm0.040)$ and $K_S(\mathrm{O{-}X}) = 0.149(\pm0.044)$. Similarly, $K_A(\mathrm{O{-}G}) = 0.011(\pm0.006)$, $K_A(\mathrm{O{-}E}) = 0.061(\pm0.014)$ and $K_A(\mathrm{O{-}X}) = 0.047(\pm0.012)$ (the standard errors were calculated by assuming a Poisson distribution for the total number of base changes and by considering, on average, 308.6 replacement sites and 78.4 synonymous sites in the sequences compared). This result suggests that the E gene accumulated more substitutions than the functional genes at both the synonymous and replacement sites, although the standard errors seem rather large. In addition, the rate of change at the replacement sites of the pseudogene, relative to the standard genes, increases more than the rate of change at the synonymous sites: the mean values are $K_A(\mathrm{O{-}E})/K_A(\mathrm{O{-}G})(=5.6) > K_A(\mathrm{O{-}E})/K_A(\mathrm{O{-}X'})(=2.9) > K_S(\mathrm{O{-}E})/K_S(\mathrm{O{-}G})(=1.7) \sim K_S(\mathrm{O{-}E})/K_S(\mathrm{O{-}X'})(=1.9) > 1$, where $K(\mathrm{O{-}X'})$ is $K(\mathrm{O{-}X})/2.25$, as, according to the phylogenetic tree of Fig. 1, the time interval between O and X is estimated to 2.25 times longer than that between O and G. These relationships are the same for each of the six different X genes. These patterns of base substitutions are similar to those of other pseudogenes analysed previously, including α-globin pseudogenes of man and mouse, β-globin pseudogenes of rabbit and mouse and immunoglobulin V_κ pseudogene of man[10], suggesting that pseudogenes show strong sequence divergence compared with functional genes, regardless of whether the mRNAs are transcribed.

A possible interpretation of these results is that in most functional genes, the replacement sites are more constrained than the synonymous sites. However, in pseudogenes the loss of functions frees the gene from several selective constraints, thereby allowing accumulation of substitutions almost uniformly over all the regions at rate higher than the rate of change at the synonymous sites of functional genes, the most rapidly evolving component (see refs in ref. 13). The fact that $K_S(\mathrm{O{-}E}) > K_S(\mathrm{O{-}G})$ suggests that even synonymous sites of functional genes are constrained, although presumably only weakly[10]. The suggestion that the IFN-α E pseudogene has evolved faster than functional genes may support the neutral theory[27], its rate of evolution may approximate to a limiting rate predicted by the neutral theory[9-11,28].

In human α- and β-globin, and rabbit and mouse β-globin gene clusters, pseudogenes are found between functionally distinct genes, that is, between the embryonic or fetal and adult genes[23-25,29]. The suggestion that the IFN-α E pseudogene was derived from the IFN-α G gene is of interest in this regard. The fact that the v_A of the G gene is smaller than that of other genes suggests that the functions of the proteins encoded by them differ. Although the complete linkage arrangement of the Hu IFN-α multigene family has not been established, this suggests that the E pseudogene may be located between the G gene and the other groups of genes. Furthermore, IFN-α C, F and H genes (group I) show close sequence homology, suggesting that they are closely linked. It would be interesting to determine whether further pseudogenes reside between this group and group II (A, B and D) or III (G). This would provide further insights into the mechanisms by which pseudogenes arise during evolution.

Goeddel *et al.*[3] found size heterogeneity in the 3'-noncoding regions of the eight distinct Hu IFN-α mRNA sequences. To trace the evolutionary origin of such heterogeneity, we have compared the untranscribed 3'-flanking sequences of Hu IFN-α_1 (a member of class D)[2] with the IFN-α B, C, E, F and H mRNA sequences in the region corresponding to that immediately after the poly(A) sites of IFN-α A, D and G mRNAs, the shortest mRNAs. We found remarkable homology: the untranscribed 3'-flanking sequence of IFN-α_1 is 74% homologous to the longest B mRNA sequence in the corresponding region. In the IFN-α_1 sequence, the hexanucleotide AATAAA, which is thought to be involved in mRNA polyadenylation and processing[30], and its variant ATTAAA were found at positions 37–42 and 115–120, respectively (see Fig. 2). Presumably the IFN-α A and G genes also contain such hexanucleotides in this region. It seems likely that the presence of multiple hexanucleotides allowed the extension of the 3'-noncoding regions of the IFN-α genes during evolution, and thus gave rise to size heterogeneity of the mRNAs. Interestingly, two hexanucleotides precede the poly(A) sites in the B and F mRNAs, suggesting that the multiple hexanucleotides in each mRNA are recognized with varying efficiency, giving rise to mRNAs having 3'-noncoding regions of different sizes from a single gene[31].

We thank Drs T. Taniguchi and T. Yasunaga for discussions and comments. This work was supported in part by grants from the Ministry of Education, Science and Culture of Japan.

H-2-like genes in the *Tla* region of mouse chromosome 17

David H. Margulies, Glen A. Evans, Lorraine Flaherty* & J. G. Seidman

Laboratory of Molecular Genetics, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland 20205, USA
* Kidney Disease Institute, Division of Laboratories and Research, New York State Department of Health, Albany, New York 12201, USA

H-2K, H-2D, H-2L, Qa-2 and TL are all members of a closely related family of cell-surface glycoproteins. The H-2 molecules (major histocompatibility antigens) are extremely polymorphic, expressed on almost all cell types and play an important part in graft rejection[1-4]. In contrast, Qa-2 and TL are much less polymorphic, and have a limited tissue distribution[4,5]. Nevertheless, all these molecules are similar in that they consist of two chains, one of which is the invariant β_2-microglobulin (molecular weight (MW) 11,500), the other a 45,000-MW glycopolypeptide[2,6-10]. The 45,000-MW H-2K and H-2D map within 0.3 centimorgans of each other in the major histocompatibility complex (MHC) on chromosome 17 (ref. 1). The Qa-2 and TL chains are encoded by genes in the closely linked *Tla* region. Recently, recombinant DNA techniques have been used to study the family of genes encoding H-2-like molecules[11-14]. The finding that cloned *H-2* cDNA hybridizes to 10–20 restriction fragments of genomic DNA has led to the conclusion that there are 10–20 *H-2*-like genes in the murine genome[11,12]. Here we present evidence that most of these genes are encoded on chromosome 17 and that at least three *H-2*-like genes map outside the MHC in the *Tla* region. We also confirm and provide further evidence that there are 10 to 15 *H-2*-like genes in the mouse genome.

Initial studies of the number of genes in the *H-2* family[11,12] used cDNA probes complementary to portions of the *H-2*-like mRNA. Thus, the precise relationship between the structure of the probe and the sequences detected in Southern blotting experiments is uncertain. If these probes span intervening sequences that contain relevant restriction sites, they would be expected to hybridize to several genomic DNA fragments from the same gene, thus overestimating the number of genes. To avoid this we used probes from the cloned genomic DNA to identify *Bam*HI restriction fragments of BALB/cN myeloma DNA that encode *H-2*-like genes (Fig. 1*a*). The 3' probe (Fig. 1*d*) and a probe that encodes amino acids 194–283 (and intervening sequence) identify similar sets of restriction fragments (D.H.M. and J.G.S., unpublished observations). In contrast, the 5' (Fig. 1*d*) and 3' probes do not identify the same fragments of *Bam*HI-digested BALB/c myeloma DNA (Fig. 1*a*). Thus, the 5' and 3' portions of some *H-2*-like genes lie on different *Bam*HI restriction fragments. However, each probe identifies 10–15 fragments. This is a minimum estimate of the gene number as we cannot be certain that our probe detects all the *H-2* genes in the hybridization conditions used and because some of the larger fragments contain two *H-2*-like genes (unpublished observation). These fragments may represent inactive or pseudogenes, and there may be other MHC transplantation genes that are not recognized by the probes. Kourilsky *et al.*[11] detected a similar pattern of *Bam*HI restriction fragments in BALB/c DNA using a probe ~85% homologous to the 3' probe used here.

The fact that the *H-2L*, *H-2D* and *H-2K* genes are all closely linked on chromosome 17 in the MHC does not mean that all *H-2*-like genes are necessarily encoded on this chromosome. To determine which *H-2*-like genes are encoded on chromosome 17, we have analysed the DNA of the cloned somatic cell hybrid, R4 4.1 (ref. 15), which contains a full complement of Chinese hamster chromosomes but only chromosome 17 derived from

0028-0836/82/020168—03$01.00

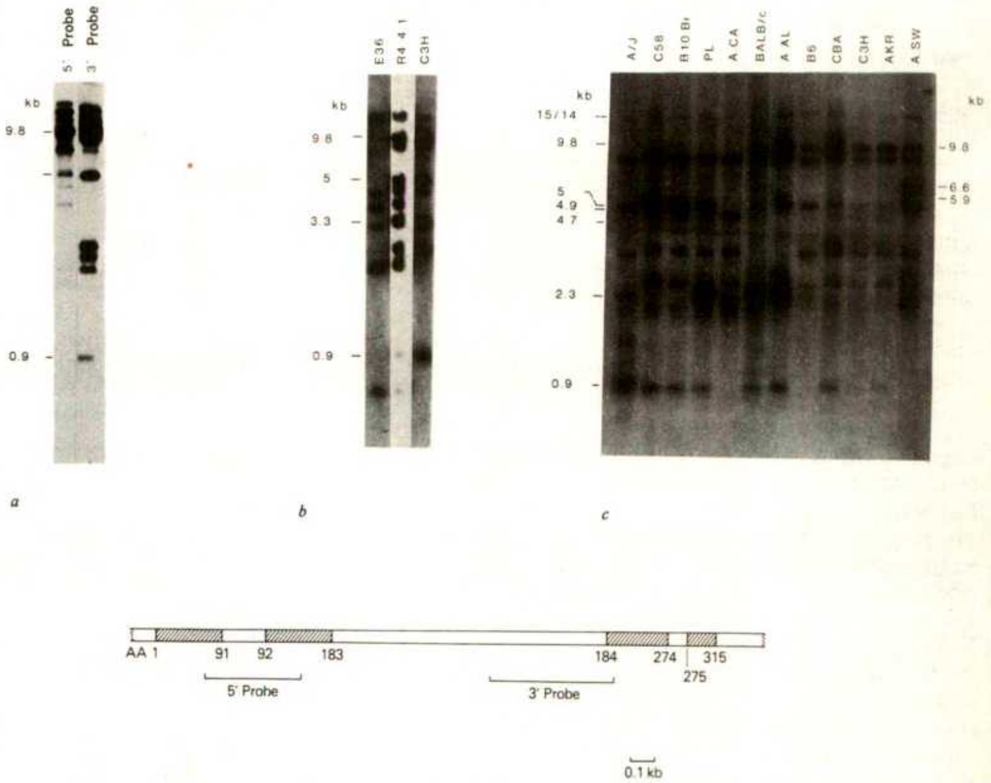

Fig. 1 Southern blot analysis of genomic DNA probed with fragments derived from an *H–2*-like gene. The structure of the *H–2*-like genomic clone and the 5′ and 3′ probe fragments derived from it are shown in *d*. This clone was isolated from the MOPC 41 (BALB/c) Charon 4A library using a fragment of a human HLA genomic clone as probe (G.A.E. and J.G.S., in preparation). This cloned genomic DNA fragment encodes a protein that is 70–90% homologous to H–2K^d, H–2D^d and H–2K^b. The indicated *Sau*3A fragments were cloned in M13mp7 as described elsewhere[18]. The subcloned fragment was separated from the replicative form (double-stranded DNA) by digestion with *Eco*RI, and purified on disulphide-linked polyacrylamide gels[19]. DNA was prepared from: BALB/c myeloma (NP-2) DNA; E36 and R4 4.1 from cultured cells; and C58 from the R1.1 cultured cell line[10]. All other DNA was extracted from livers of mice obtained from either Dr I. Egorov (BALB/cBy) or Dr J. Berzofsky (B10.Br), Jackson Laboratories, or *Tla* and *Qa* recombinant strains[4,5]. Digestion of the DNA *Bam*HI endonuclease, electrophoresis in 0.8% or 1.0% agarose gels (*a*), blotting to nitrocellulose filters, hybridization to the nick-translated probes (specific activity between 2.0 and 4.0×10^8 c.p.m. per μg), washing in 0.015 M NaCl, 0.0015 M Na citrate at 50 °C, and autoradiography were all as described elsewhere[21–23]. Sizes of fragments (in kilobases) are indicated. *a*, BALB/c DNA (NP-2) probed with 5′ and 3′ probes; *b*, Chinese hamster E36, mouse × hamster hybrid clone R4 4.1, and C3H DNAs probed with the 3′ probe; *c*, genomic DNA from the indicated strains (BALB/c, BALB/cBy liver; B6, C57BL/6); *d*, structure of the *H–2*-like genomic clone and derivation of its probes. Shaded areas indicate coding blocks and adjacent amino acids are indicated.

the mouse L cell parent. The *Bam*HI restriction fragments identified in digests of genomic DNA from E36 (Chinese hamster cell), R4 4.1 and C3H (parent of the L cell) are indicated in Fig. 1*b*. Fragments derived from R4 4.1 DNA but not E36 DNA must be encoded on chromosome 17. There are many genes encoded in the hamster genome that hybridize to the H–2 probe. However, the chromosomal location of mouse-derived restriction fragments that co-migrate with hamster-derived restriction fragments cannot be determined from this experiment. Nevertheless, there are at least seven murine-derived restriction fragments in the R4 4.1 DNA digests. Thus at least seven of the 10–15 *H–2*-like genes are encoded on murine chromosome 17.

A unique feature of the H–2 antigens is their extreme polymorphism among inbred mice. Using the 3′ probe to examine the *Bam*HI-derived restriction fragments from a series of inbred mouse strains (Fig. 1*c*), we found that these patterns are similar overall. The number of restriction fragments encoding *H–2*-like genes was similar in the different strains. Thus, the number of *H–2*-like genes does not vary widely among the inbred strains examined. In addition, many fragments (~50%) were common to different mouse strains both in the *Bam*HI digest shown here, and in digests using other enzymes (*Xba*I and *Eco*RI) (unpublished observations). However, comparison of the H–2K and H–2D types (Table 1) of these strains and their restriction fragment pattern (Fig. 1*c*) suggests that there are only a few fragments specific to a *H–2* haplotype. For example, A.SW has two unique fragments of 6.6 and 5.9 kilobases (kb) not found in other strains. These *H–2*-specific fragments may reflect differences in the major histocompatibility antigens of these mice.

There are differences in three restriction fragments between these mouse strains that have a distinct pattern, but which do not reflect the H–2 type of a particular strain. For these cases, if a strain lacks a particular restriction fragment, it is replaced by another, compensating fragment. The surprising feature is that the replacement fragment is the same in several strains. For example, five strains have a 2.3-kb fragment (A/J, PL, BALB/c, A.AL, B6) while the strains that lack this fragment (C58, B10.Br, A.CA, CBA, C3H and AKR) have a 4.7-kb fragment. A.SW is an exception to this rule, lacking both fragments. There are two further examples of this type of compensatory polymorphism: (1) nine strains (A/J, C58, B10.Br, PL, BALB/c, A.AL, CBA, C3H and AKR) have 0.9-kb and 14-kb fragments, while three strains (A.CA, B6, A.SW) replace these with a 15-kb fragment. (2) A 9.8-kb fragment is found in BALB/c, A.AL, B/6, CBA, C3H, AKR and A.SW and is replaced by a 4.9-kb fragment in A/J, C58, B10.Br and PL. A.CA appears to lack the compensatory 4.9-kb fragment. From these patterns we make the following conclusions: (1) Each of these fragments, and their compensatory fragments, represents a single mutational event that affects a single *H–2*-like gene or its flanking sequence. (2) Apparently, each band identified in the Southern

A.AL	k	d	ND	c
B6	b	b	a	b
CBA	k	k	b	b
C3H	k	k	b	b
AKR	k	k	b	b
A.SW	s	s	a	b

The phenotypes for the inbred mouse strains are taken from Klein *et al.*[17]. ND, phenotype not determined.

* The phenotype of BALB/cJ is indicated here; the BALB/cBy (*Qa-2,3^b*) analysed in Fig. 1*c* apparently is an exception to the correlation of the presence of the 2,3-kb fragment with *Qa-2,3^a*. However, as it is likely that this is an independent mutation that occurred in a subline of BALB/c, one would not expect it to have the same restriction fragment pattern as other *Qa-2,3^b* strains. (Based on the genomic blot analysis, we can make tentative assignments of the *Qa-2,3* and *Tla* types of the unassigned strains as follows: PL, *Qa-2,3^a*; A.AL, *Qa-2,3^a*.)

blot corresponds to a single fragment in the mouse genome. Presumably, identical multiple mutations would not occur in different genes. (3) Each of these mutations must have occurred before the inbred lines were separated from each other. As several strains (for example, BALB/c, AKR and PL) have distinct origins, we suggest that these mutations occurred in the wild mouse population. The fact that these patterns do not correlate with the H–2 type of the strains suggests that either the mutations segregated independently of the H–2 type during evolution, or the *H–2* haplotypes have been generated by independent mutation since the original mutations occurred.

To test the hypothesis that these polymorphisms segregate with other known genes encoded in chromosome 17, we compared the Qa-2,3 and Tla phenotypes of these strains (Table 1) with their restriction fragment patterns (Fig. 1*c*). The 4.7-kb fragment was found in the $Qa\text{-}2^b$ strains while the 2.3-kb fragment was found in $Qa\text{-}2^a$. The 9.8-kb fragment was found in all Tla^b and Tla^c strains and the 4.9-kb in all Tla^a strains. Furthermore, A.CA, the only strain of the Tla^d haplotype examined, lacks the 9.8-kb as well as the 4.9-kb fragment. This suggests that the mutation separating Tla^b from Tla^c occurred more recently than the mutation distinguishing them from Tla^a. The presence of the 0.9-kb fragment does not correlate with the H-2, Qa-2,3 or Tla phenotypes.

The correlations suggested by examination of polymorphisms in inbred strains of mice might be misleading: the finding of a fragment in one inbred line and its replacement in another might reflect the history of these strains or the chance co-migration of several restriction fragments. Fortunately, several congeneic strains of mice have been isolated which have undergone recombination in the vicinity of the *Qa-2,3* and *Tla* genes[3,9]. We have examined the DNAs of these strains to determine the map location of the restriction fragment polymorphisms (Figs 2, 3). Again, the 2.3-kb/4.7-kb polymorphism maps with the Qa-2,3 phenotype, and the 9.8-kb/4.9-kb fragments with the Tla phenotype. Recently, Steinmetz *et al.* have mapped a 2.7-kb *Bam*HI fragment to the *Qa-2,3* region[16]. The 0.9-kb polymorphism does not segregate with either the Qa-2,3 or the Tla phenotype. However, these recombinant strains allow us to map this polymorphic *H–2*-like gene to the left of the *Tla* gene (as the fragment is found in $A.Tla^b$, but not in B6) but to the right of *H–2D* (as the fragment is found in B6.K1 but not in $B6.Tla^a$).

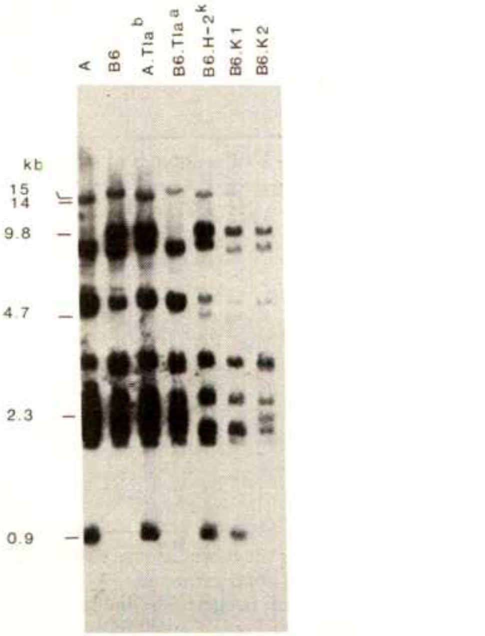

Fig. 2 Restriction fragment analysis of DNA from *Tla* and *Qa* region of congeneic mouse strains. DNA from the indicated strains was analysed as described in Fig. 1 legend. Band intensity is a complex function of various factors. The greater intensity of the 2.5-kb fragment in strain A is a more usual result than the faint intensity of the same DNA seen in Fig. 1.

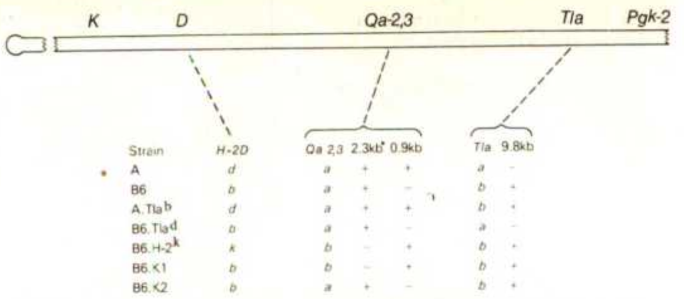

Strain	H-2D	Qa 2,3	2.3kb*	0.9kb	Tla	9.8kb
A	d	a	+	+	a	-
B6	b	a	+	-	b	+
A.Tla b	d	a	+	+	b	+
B6.Tla d	b	a	+	-	a	-
B6.H-2k	k	b	-	+	b	+
B6.K1	b	b	-	+	b	+
B6.K2	b	a	+	-	b	+

Fig. 3 Mapping of the *Tla* region polymorphism on chromosome 17. A schematic map of the relevant region on chromosome 17 is drawn to scale after Klein[1]. The distance from *K* to *D* is 0.33 cm, and from *D* to *Tla* 1.3 cm. *Qa-2,3* maps between *D* and *Tla* but its precise location is unknown. * Size of fragment indicated in Figs 1*c* and 2.

The presence of a 14-kb fragment that moves to 15 kb in the strains lacking the 0.9-kb fragment suggests that either this polymorphism contains a *Bam*HI site or that there are two *H–2*-like genes within 15 kb of each other. Thus, there are at least three *H–2*-like genes encoded in the *Tla* region, although these genes may not be *Qa-2,3* and *Tla*.

These studies, using cloned genomic fragments from an H–2-like molecule as a molecular probe demonstrate that: (1) there are at least 10–15 *H–2*-like genes encoded in the mouse genome; (2) at least seven of these are encoded on chromosome 17; and (3) there are at least three *H–2*-like genes encoded outside the MHC which map to the *Tla* region. Future analysis of cloned *H–2*-like genes will permit a comparison of genes from the MHC with the *Tla*-encoded genes defined here. The basis for differences in the polymorphism and expression of the MHC and *Tla*-encoded genes may be reflected in their nucleotide sequences.

We thank Drs J. Strominger and S. Weissman for providing HLA cDNA clones needed in the early stages of this work, Dr I. Egorov and J. Berzofsky for mouse strains, Dr P. d'Eustachio for the somatic cell hybrid line and Dr J. Michaelson for stimulating discussions of *Qa* and *Tla*. We also thank Ms Terri Broderick for editorial and secretarial assistance. This work was supported in part by NIH grant AI12603 awarded by the onal Institute of Allergy and Infectious Disease (PHS DHHS).

Note added in proof: Subsequent studies have demonstrated that the molecular probes used in these experiments are derived from the $H\text{-}2L^d$ gene[24].

MATTERS ARISING

A pitfall in random sampling

MANY statistical tests depend on random samples. A random sample can be defined[1] as a sample from a distribution (for a univariate distribution this is an area) in which each point or neighbourhood has the same probability of being chosen. It is therefore necessary to pay close attention not merely to the process of sampling, but also to the nature of the distribution itself. It is sometimes easy to misinterpret a distribution and thereby invalidate the resulting test. For example, one can treat as stationary a distribution which may change over time. So stated the trap is obvious, but it can be subtle and occasionally catches excellent biologists. The question is totally different from estimating the shape or position of an average distribution determined *post facto* from a non-stationary process. Such an average distribution exists statistically but may have no causal meaning; an obvious example is the joint distribution of annual income of all residents of London since 1800.

Cole[2] criticizes the work of Evans and Murdoch[3], who showed that herbivorous insect species in a community are a roughly constant proportion of all insect species over a season, despite much turnover. They therefore showed that the distribution is stationary, an important result. Cole not surprisingly found that Evans and Murdoch's data are not significantly different from what they would be if they were random samples of the same size from the total species pool. He then concluded that the data are irrelevant to ecological processes.

The fallacy is in assuming that there is a uniform pre-existing population from which samples are drawn (commonly without replacement, which affects the statistics in a subsidiary way). However, the very existence of such a stationary population is the interesting question, because it implicitly assumes that the relevant properties (here, diet) of the species sampled at different times are the same. Otherwise there would be no overall distribution which could be sampled randomly, and no reason to expect approximate constancy over time in the proportion of herbivores.

Thus, the results of Evans and Murdoch[3] do add support for the idea of a dynamically maintained balance in trophic structure. This balance also has other aspects, notably in energy flow, and its control remains a central problem in ecology[4].

Anomalous ^{13}C depletion in Precambrian organic carbon

SOME isotopic analyses of Precambrian reduced carbon which is strongly depleted in the heavier ^{13}C isotope have been reported by Schoell and Wellmer[1]. They have argued that these anomalous graphitic carbons might be isotopically light as the result of a fractionation related to methane bacterial action in the Precambrian. This argument is quite reasonable insofar as it assumes that the organic carbon in most Precambrian and early Phanerozoic sediments is itself normal. However, the average isotopic value of such reduced carbon is normal only from the experimental standpoint. When placed in context with the algal biota presumed to have been responsible for its origin and overall composition, it is also anomalously depleted of ^{13}C.

In Fig. 1 of ref. 1, and in other similar compilations[2–5], the mean values for δ^{13}C(PDB) cluster around −24 to −28‰. Such values appear quite normal when compared with the reduced carbon of modern C_3 terrestrial plants[3,4,6,7]. However, a substantial land plant community did not develop until the Silurian, so that when compared with the reduced carbon from modern marine algae and algal mats, these 'normal' Precambrian isotopic ratios become disturbingly anomalous, and are especially so for the carbonate stromatolites[5,8]. Present-day marine algal organic carbon is significantly heavier isotopically, with mean values ranging from −18 to −20‰ (refs 3, 4). Modern marine algal mats are even heavier[8–12], with values ranging from −8 to −19‰. This difference between the average terrestrial isotopic values and the average marine values of reduced carbon is so striking that it has been used to evaluate the impact of land-derived organic matter in modern marine sediments[13,14].

In the absence of a significant terrestrial biota in the Precambrian, how can average values ranging from −24 to −28‰ be explained? Those who have discussed this problem (see refs 3, 8, 10, 12, 15) have variously concluded that the depletion might be the results of: preferential diagenetic enrichment of isotopically light (lipid) fractions; a higher CO_2 partial pressure in the Precambrian environment; or perhaps different primitive metabolic fractionations.

When compared with data on ancient organic matter having both carbon isotopic and H/C atomic ratios[2,16,17], recent laboratory-simulated thermal maturation experiments on algal mat kerogen[11] do not support the diagenetic argument. In these experiments only the most immature algal mat kerogens showed any tendency towards ^{13}C depletion; all mature kerogens (H/C atomic ratios <1.0) were enriched in ^{13}C.

Some laboratory experiments with marine algae grown under elevated CO_2 (1.5 to 3.5%) have produced carbon isotope ratios consistent with the idea of an increased level of CO_2 in the Precambrian[10,15]. But the low cell densities involved and the absence of a potential for bicarbonate-derived CO_2 in these experiments makes them doubtfully applicable to the conditions in which the carbonate stromatolite mats of the Precambrian thrived.

While the very depleted values reported by Schoell and Wellmer[1] and others[2] are certainly anomalous in their own right, and may be the result of Precambrian biogenic methane, a more important anomaly remains. Until the average isotopic composition of organic carbon in a variety of Precambrian and Phanerozoic marine deposits can be explained in a consistent fashion, interpretations of the data to infer the physiology of the organisms involved, or the environments in which they were living, must be considered as tentative. This is especially important to timing the onset of oxygenic photosynthesis in the early history of life[18].

0028-0836/82/010171—02$01.00

SCHOELL AND WELLMER REPLY— Towe has raised some often repeated questions which, however, are not directly relevant to our paper. We aimed to explain why some Precambrian graphites are depleted in ^{13}C compared with the bulk of all other Precambrian graphites. We offered an explanation by suggesting local phenomena such as CO$_2$ from oxidized methane as a food source for the original biota, rather than worldwide phenomena or completely different geochemical processes. However, Towe's comment indirectly bears on our argument and deserves a brief reply.

Two questions have been raised: why some organisms, specifically marine algae, are enriched in ^{13}C compared with common kerogens; and why Precambrian and early Phanerozoic kerogens are isotopically more enriched in ^{13}C as compared with modern marine algae and algal mats.

These problems have already been discussed by previous workers[1,2], who concluded in part that marine algae as found today could not have been the predominant precursor of Precambrian reduced organic matter. Recent work on the Precambrian argues for an establishment of a flourishing yet primitive life already 3,500 Myr ago[3,4]. Detailed work on marine phytoplankton[5] revealed a range of carbon isotope fractionation between HCO$_3^-$ and organisms ranging from −22 to −35‰ (the mean of which interestingly is −27.5‰). The carbon isotopic composition was found to depend on the species and on local conditions (pool size effect). The above figures easily explain the range of 'normal' Precambrian reduced organic matter.

The observation of relatively heavy carbon in less than half a dozen modern algal mats hitherto investigated does not justify the general statement of Precambrian organic matter as being 'disturbingly anomalous'. On the contrary, we emphasize the isotopic similarity of Precambrian, Phanerozoic and recent organic matter and consider this similarity as an argument for the early establishment of biological carbon fixation based on the presently operating enzymatic pathways, that is as proof for (1) the extreme antiquity of CO$_2$ fixation (notably by the RuBP carboxylase reaction) and (2) the constancy of the isotopic composition of the Earth's pool of inorganic carbon (atmospheric CO$_2$ and marine bicarbonate).

We thank M. Schidlowski for careful reading of this manuscript.

Are monozygotic twins similar due to genetic factors alone?

THE number of errors and inconsistencies in the paper by Gärtner *et al.*[1] raises doubts about the validity of their conclusions. In Table 1, the mean and standard deviation of 51-day-old monozygotic (MZ) males are incorrect and differ from the mean and standard deviation for the same data given in Table 2. For 51-day-old dizygotic (DZ) males the authors estimate the between-pairs component of variance as +1.18 when the correct value is either zero, since it is not significant, or negative. This error is repeated for the same data in Table 2 where in addition, the same error is made for body weight of DZ males, aged 61 days. Also in Table 2, the *F* ratios between estimates of the variance components s_b^2 for MZ and DZ twins are incorrect. The ratios are not *F* tests; the degrees of freedom attributed to them are incorrect as are, therefore, the probabilities. Furthermore, for reasons which are not discussed in the text and which are not obvious, these probabilities appear to be one-tail. Even if the between-pairs items had been compared using correct tests, it is difficult to see what conclusions could have been drawn for the many characters for which, according to Table 2, MS$_w$s differ significantly between MZs and DZs.

Incidentally, the estimates of MS$_w$ cannot take the extremely small values that are given in Table 2 unless their true values are zero and the values given are rounding-off errors or arbitrary. The assumption of "random effects" is superfluous for the analysis used, and an explanation is required for pooling males and females for some characters and omitting females for others when the authors say that all statistics were calculated separately for males and females.

Finally, there are features of the data which are difficult to reconcile with the explanation given by the authors. For example, examination of body weight in females from 31 to 61 days shows that the DZs, as expected, retain their initial level of variability as reflected in the total variance. Indeed, this variance increases slightly with age. In complete contrast, on the same criterion the MZs are as variable as the DZs at day 31, but lose their variability as they age. Indeed at day 61, they display almost no variability at all. Since the main conclusion of this paper is that there is a lower level of variation within the MZs than the DZs and that this can be attributed to events that occur early in life, it is difficult to see why these MZ females reached their maximum variability early in life and their minimum as adults.

1. Gärtner, K. & Baunack, E. *Nature* **292,** 646–647 (1981).

GÄRTNER AND BAUNACK REPLY— Our results[1] show that pairs of sexually concordant isogeneic DZ twins differ more than pairs of MZ twins because of a non-genetic mechanism which modifies each zygote differently before the third cell division. We thank Jinks and his coworkers for drawing attention to a few errors in our paper. However, these errors do not affect our conclusion as the similarity within the pairs of MZ is clearly much greater than that within DZ twins of inbred mice whatever the method of statistical analysis. Therefore the valid criticism of Jinks *et al.* of the *F* values for testing the between variance components (s_b^2) does not influence our main conclusion. Nor do the two regrettable errors they mentioned in printing different numbers in Tables 1 and 2 for the 51-day MZ body weights and the absence of the minus sign for the DZ 51 and DZ 61 variance components.

Further discussion of the statistical procedure helps only to a very small degree. To shorten this discussion we are prepared to send to any interested scientist our original data for statistical analysis by a method of his/her own choice.

We do not accept the other criticisms. The first three variables of Table 2 (appearance of the hair, eye opening, ear opening) are data measured in whole days. All the MZ pairs exhibited the event on the same day. It seems unrealistic to compare the alteration of the variance in the MZ female twins as Jinks *et al.* suggest, because of the very small numbers of female MZ twins.

Further confirmation can only come from the results of similar experiments in other laboratories. However, further experiments in our own laboratory using twins produced since our original paper, together with many additional characters, support our conclusions.

BOOK REVIEWS

Once a jackass...

Marie Jahoda

IN July 1974, James Watson of *Double Helix* fame was one of the 11 eminent scientists who asked publicly for a voluntary moratorium on two types of experiment involving genetic manipulation. In 1979 Watson described the signatories as "jackasses" who displayed a complete lack of scientific judgement in asking for the moratorium. What happened in between, before and after these dates forms an extraordinary episode in the history of science. Confirming all one's prejudices about national character, events unfolded as a mixture of drama, confrontations, public soul-searching and farce, with the participation of a large and excited lay public in the United States; the issues were the same in England, but working parties rather than public meetings wrestled with them and lay participation was limited to a few individuals on GMAG, the Genetic Manipulation Advisory Group (of which I was one). Lest this contrast between the phlegmatic English and the excitable Americans foster unwarranted interpretations, it should be said immediately that it was the American response that crystallized the questions and dilemmas that the marvellous advances in genetic manipulation present.

The DNA Story: A Documentary History of Gene Cloning. By James D. Watson and John Tooze. Pp.605. ISBN 0-7167-1292-X. (W.H. Freeman: 1981.) $24.95, £17.30.

In this beautifully produced and illustrated volume consisting largely of facsimile documents, Watson and Tooze leave it to the reader to infer the basic questions but emerge with only one clear answer: leave genetic manipulation to the scientists; no special foreseeable hazards are involved, hence no special regulations are required. Apparently the vast majority of the biological establishment in the United States now agrees; but not all, and some Nobel Prize winners are among the dissenters. That scientists disagree among themselves and change their minds is not news. Watson's recantation confirms that even great scientists are only human. Robert Sinsheimer, however, changed his mind in the opposite direction. Everybody's right to be a "jackass" once in a while admitted, how can one decide who is one when? Only the future will tell, but if the Sinsheimers are right, the answer may come too late.

DEPARTMENT OF MOLECULAR BIOPHYSICS
AND BIOCHEMISTRY

July 17, 1973

Dr. Philip Handler, President
National Academy of Sciences
2101 Constitution Avenue
Washington, DC 20418

Dear Doctor Handler:

We are writing to you, on behalf of a number of scientists, to communicate a matter of deep concern. Several of the scientific reports presented at this year's Gordon Research Conference on Nucleic Acids (June 11-15, 1973, New Hampton, New Hampshire) indicated that we presently have the technical ability to join together, covalently, DNA molecules from diverse sources. Scientific developments over the past two years make it both reasonable and convenient to generate overlapping sequence homologies at the termini of different DNA molecules. The sequence homologies can then be used to combine the molecules by Watson-Crick hydrogen bonding. Application of existing methods permits subsequent covalent linkage of such molecules. This technique could be used, for example, to combine DNA from animal viruses with bacterial DNA, or DNAs of different viral origin might be so joined. In this way new kinds of hybrid plasmids or viruses, with biological activity of unpredictable nature, may eventually be created. These experiments offer exciting and interesting potential both for advancing knowledge of fundamental biological processes and for alleviation of human health problems.

Certain such hybrid molecules may prove hazardous to laboratory workers and to the public. Although no hazard has yet been established, prudence suggests that the potential hazard be seriously considered.

A majority of those attending the Conference voted to communicate their concern in this matter to you and to the President of the Institute of Medicine (to whom this letter is also being sent). The conferees suggested that the Academies establish a study committee to consider this problem and to recommend specific actions or guidelines should that seem appropriate. Related problems such as the risks involved in current large-scale preparation of animal viruses might also be considered.

A list of participants in the Conference is attached for your interest.

Sincerely yours,
Maxine Singer and Dieter Söll

The debate widens: the letter expressing concern over aspects of recombinant DNA research written by Maxine Singer of NIH and Dieter Söll of Yale to Philip Handler, President of the National Academy of Sciences. This letter, and another to *Science*, were the upshot of the 1973 Gordon Conference on Nucleic Acids, a private meeting attended by some 130 molecular biologists.

In less colourful terms than Watson uses in his pungent and engagingly informal prose, the question is whether those at the very forefront of science can foresee the consequences of their achievements. The answer is an unqualified no. One remembers Rutherford on splitting the atom. Even Watson himself, talking about the double helix, says ". . . we did not foresee any immediate practical consequences for the world about us . . ." (p.vii), yet his and Crick's discovery was the *sine qua non* of genetic manipulation. When the consequences became clear shortly after, the scientists themselves stopped in their tracks. Why? At the risk of being laughed out of court by these superior rational minds, I suggest that they were overcome by a metaphysical awe at their own power to fiddle with the very building blocks of life. Watson's self-derogatory explanation that he acted originally in a fit of liberal conscience is a bit superficial — conscience in scientists and others had better come not just in occasional fits. That metaphysical awe was akin to Oppenheimer's experience in witnessing the first atomic bomb explosion, and when it communicated itself to the public all hell broke loose. The unforgettable Mayor Velucci of Cambridge, Massachusetts, asked the Academy of Sciences to investigate whether the reported sighting of a monster could be due to genetic manipulation. Not the monster but the "sighting" revealed one theme underlying the debate that preoccupied not only Velucci but also some scientists and many others: the fear of the power of science that could deliberately, not accidentally, change the very nature of living creatures. The other theme, inherent in the position of Watson and his friends, concerned technicalities, not metaphysics, the avoidance of accidents, not the unforeseeable outcome of their deliberate efforts. That the technical theme won in the end is due not only to the greater sophistication of its proponents but also to the fact that the metaphysical question is unanswerable — which does not, however, eliminate it. Fears and hopes were vastly exaggerated and opinions about the unforeseeable polarized. Scientists on both sides of the public debate spent for years large proportions of their time not in research but in lobbying Congress and state governments, and in writing and speaking for the public media. Unused though they were to political manoeuvrings, those on Watson's side did pretty well. The NIH guidelines were significantly relaxed, as were GMAG's procedures, and the scientists, bruised but relieved, could return to their work. The issues raised by the episode remain, however.

During these eventful years some suggested that all genetic manipulation should be stopped. Even if it were desirable, this cannot be done. Short of nuclear catastrophe the acquisition of scientific knowledge is an irreversible process; for better or worse we have to live with it. The question is how? Watson is against all regulations, as is Norton Zinder who believes that recombinant DNA research is ". . . as safe as most other biological research and safer than that dealing with a number of very dangerous microorganisms . . ." (p.201). These scientists defend their wish to be left alone by pointing to other uncontrolled hazards and regard the good sense of the scientific community as sufficient guarantee of safety. Such arguments are suspect because they are so clearly interwoven with self-interest. Richard Novick expressed this best when he declared himself unable to distinguish between the following two statements as bases for his belief that the experiments were safe:

> 1. I am convinced they are not dangerous, and therefore it is ok to do them; or 2. I have convinced myself they are safe precisely because I want to do them! [p.149].

If the whole episode demonstrates one thing it is that there is no harmonious scientific community interested only in the advancement of knowledge and its benefits for mankind. Yes, there is passionate commitment to driving forward their breath-taking discoveries; but there is also ambition, jealousy, lack of foresight, moral ambiguity and arrogance in these scientists, and there is absolutely no reason to assume that they are any better in these matters than we of a lesser breed. It seems reasonable to require that some people whose self-interest is not vested in genetic manipulation should be involved in monitoring these experiments.

This, of course, is easier said than done. Lay participation, as in the United States at the height of the controversy, may only have strengthened the irrational and anti-science trends in society. It has not bridged the enormous gap in knowledge between the scientists and the general public. Lay participation as in England is token participation, symbolic rather than real. What can a lay person do, when scientists disagree about the containment category of a given experiment, but side with the one with the bluer eyes? Perhaps such frustration about one's technical incompetence will be mitigated when issues arise about which we all are equally competent or incompetent. One such issue, though not restricted to genetic manipulation, arises over the possibility of cloning human beings. Sir Peter Medawar (p.246) considers this well nigh impossible but reports that Jacques Monod did not. John Maynard Smith agrees with Monod.

The great merit of Watson and Tooze's book is that it displays the arguments on all sides. It offers only personal, not general solutions to fundamental questions. The worst sequel to this whole exciting episode would be if young scientists decided to withdraw into their ivory towers; the best if it were regarded as a rehearsal for things to come, from which to learn how ill-prepared scientists and the public still are to face the issues that confront them jointly and how to improve their relations while there is time. ☐

Irish rocks reviewed

W.S. McKerrow

A Geology of Ireland. Edited by C.H. Holland. Pp.335. Hbk ISBN UK 0-7073-0269-2, ISBN US 0-470-27247-3; pbk ISBN 0-7073-0308-7. (Scottish Academic Press/ Halsted: 1981.) Hbk £27.50, $49.95; pbk £15.

MOST geologists know that the British Isles contain rocks of unusually diverse types and ages for such a small part of the world. Ireland is as varied and complex as any other part of these islands; thus it is good to be provided with a concise review of Irish geology. In the final chapter (on the history of Irish geology) we are reminded of the lean years between 1914 and 1947 when significant advances were made in only two branches of geology in Ireland: Tertiary igneous petrology, and Pleistocene stratigraphy and geomorphology. This was followed by a revival in which both academic and economic geologists, mainly from outside Ireland, played a part. In the past two decades Irish geologists (living in Ireland, if not all of Irish descent) have performed an increasing amount of the geological research in Ireland. The ten contributors to the book have each spent much or all of their professional careers in Ireland, eight in Dublin and two in Belfast, and each of them is an authority in his own field.

In the preface, Professor Holland points out that a lot has happened in our understanding of Irish geology since Charlesworth's *Historical Geology of Ireland* was published by Oliver & Boyd in 1963, but this book follows a very different pattern. While Charlesworth attempted to refer to every paper (good, bad and indifferent) on Irish geology, and thus is still a good source for the older literature, Holland has been much more selective; and while Charlesworth covered the whole country single-handed, Holland has gathered a team for the task. The authors each possess an individual style and range of expertise, but the editor has clearly stamped his authority on the book. Each chapter is a very readable, well-illustrated, resumé of our knowledge and understanding of Irish geology today. (Or is it yesterday? Most chapters make little reference to work later than 1976, and most fail to include references later than 1978).

In addition to the chapters on stratigraphy, there are sections on tectonics, igneous activity and geophysics, which might be expected in such a general review. More unexpected, especially to those geologists who regard drift as a nuisance, are the fascinating chapters on the Quaternary, which extend well past the 5,000 BP date of the first Irishmen, and are almost continuous, with no more than small non-sequence, through to the final, historical chapter.

Economic geology has played, and is continuing to play, a major part in Irish life, from the Bronze Age copper mines of County Cork to the search for offshore oil today. The review includes clear descriptions of the major metal mines, together with a summary of opinions on the possible origins of the ore bodies. The section on oil and natural gas contains a useful summary of the offshore geology around Ireland, from the Celtic Sea to the Rockall Plateau.

A Geology of Ireland will prove to be a useful book for the student who wishes to obtain a general view of Irish geology; it should therefore find a place in every geology library. But the research geologist, academic or economic, may not find all that he requires in the text, or, more seriously, in the references — the editor has limited them to a level which I would consider to be lower than satisfactory. The Geological Society of London *Special Reports* on the correlation of rocks in the British Isles do provide many of the missing references, but some of these are now even more out of date than the references listed in the book. ☐

W.S. McKerrow is a Lecturer in the Department of Geology at the University of Oxford.

Joseph Henry: letters from America

Colin Russell

The Papers of Joseph Henry, Vol. 4: January 1838–December 1840, The Princeton Years. Edited by Nathan Reingold. Pp.475. ISBN 0-87474-792-9. (Smithsonian Institution Press, Washington DC: 1981.) $30.

JOSEPH Henry (1797–1878) was an American physicist and a researcher in electricity and magnetism. He had the misfortune to be a contemporary of Faraday by whom he has been considerably overshadowed; even when he emerges from the penumbra of the great Englishman he is not seen as a major luminary in science, and one may wonder at the colossal expenditure of labour in this reprinting of his papers. If it may not be justified in terms of Henry's inherent scientific stature, the rationale would appear to lie in his position within the community of early nineteenth-century science, particularly in America. He knew almost everyone of importance on both sides of the Atlantic, and such people flit effortlessly in and out of his correspondence. To read his papers is to gain a richer understanding of the social milieu in which Henry lived and much of modern physics took shape.

During most of the period covered by this book (1838–1840) Henry's life was fairly uneventful, concerned mainly with his family at home or seriously fulfilling his calling as Professor of Natural Philosophy at Princeton. For this reason the present volume lacks something of the punch and zest of its predecessor (for review see *Nature* **286,** 311; 1980), which dealt mainly with his grand tour of Europe. However there are compensations, and a large proportion of the book is concerned with his "records of experiments" from manuscript material. Some of his work was over-hasty as he wished to establish priority over Faraday, but here is an unselfconscious record of one man working under great pressure to unravel the complex phenomena of electromagnetism. Amongst his most significant discoveries of this time was that of electric induction across great distances, leading him to take the side of those who advocated an all-pervasive ether, thus anticipating in certain respects the more comprehensive theories of Maxwell.

In the correspondence a note that constantly reappears is that American science must at all costs be protected from the quacks and the charlatans (amongst whom he numbers the egregious Samuel Morse). In this respect New York was worse than Philadelphia, but the danger was endemic in a small beleaguered community of science that lacked the checks and balances of its older European counterparts. Much could be learned from Europe, of course, and America had its English-sounding Society for the Promotion of Useful Arts, while the American Association for the Advancement of Science was consciously modelled on the British equivalent. But Henry (who had been unfairly savaged at a BAAS meeting a few months earlier) very much preferred a meritocracy of science to the arrangements in Britain, in which "wisdom" and "ignorance" were mixed and where the Society was "quite as aristocratical as the government of the nation". Thus we are offered a view of British science which is rather different from that purveyed by the popularizers and promoters in Britain itself.

As in previous volumes of this series there is a short introduction, very full footnotes (which include indications of variant readings) and an excellent index. Diagrams are reproduced in facsimile and there are several pages of portraits and illustrations. One or two editorial statements raise an eyebrow here and there (for example that the preparation of magnesium was "first reported" in 1831) and on p.310 two lines have been transposed. However, as we have come to expect, the standard of production is generally superb, with the luxury of footnotes at the bottom of the page or at the end of each document. When several publishers are charging twice as much for shorter works, with much less lavish presentation, this book is a rare bargain for all concerned with history of nineteenth-century physical science. ☐

Colin Russell is Professor of History of Science and Technology at the Open University. His most recent book, Science and Social Change, *will be published by Macmillan, London, later this year.*

Standard methods in geomorphology

C. Kidson

Geomorphological Techniques. Edited by Andrew Goudie. Pp.416. Hbk ISBN 0-004-551022-3; pbk ISBN 0-004-551043-1. (George Allen & Unwin: 1981.) Hbk £25, $60; pbk £12.95, $29.95.

GEOMORPHOLOGY, the science which seeks to understand the processes which shape the surface of the Earth, lies in the borderland between geography and geology. In the United States it is firmly based in geology. In Europe, however, most of the recent major developments in the subject have, by and large, been the work of physical geographers. The British Geomorphological Research Group, for whom this volume is edited, have, as a subject group of the Institute of British Geographers, been in the forefront of research in this field. Thus it is entirely appropriate that an attempt to bring together those techniques, both field and laboratory, most appropriate to the discipline should emanate from this active and distinguished group of geographers. In a sense, the book is a natural development from their successful series of *Technical Bulletins,* two-thirds of which are referred to in the text. It does, however, go well beyond the scope of that series.

A prime objective of a "manual of useful techniques" should be to provide a work of reference for those who wish to improve their technical repertoire. Kummel and Raup's *Handbook of Palaeontological Techniques* (W.H. Freeman, 1965) is an example of what can be achieved. In its better sections, *Geomorphological Techniques* matches the high standards set in that volume — Parts 3 (*Material Properties*) and 4 (*Process*) are as useful and authoritative summaries as the readers of the book could hope to find. In others, however, notably the first two parts on form and time, the techniques are enclosed in a matrix of theory and philosophy which suggest a textbook rather than a manual. In falling between two stools the value of these parts is reduced.

Inevitably, in a volume arranged on the basis of form, materials, process and time, and written by more than 30 authors, there are some techniques which have been inadequately dealt with or even omitted. Topographic survey methods such as levelling are superficially treated. Plane tabling, which one would have thought to be basic to students of landforms, is totally omitted. The collection of samples with the aid of augers, corers and drills is scarcely mentioned, with the notable exception of the section on glacial processes and that on peats and lake sediments. In addition, the coverage of tracer techniques is woefully inadequate.

Surprisingly, for a work of this calibre, there are some remarkably superficial statements. On p.8, for example, it is asserted that "During the predominance of denudation chronology, data acquisition was dominated largely by qualitative field observations and subjective map analysis". No one who had been in the field with Wooldridge or Cotton, or who had attended a class in cartographic analysis with Hollingsworth, could conceivably have made such such a meaningless generalization.

Despite its imperfections this is a useful contribution to this vigorously growing science. It is the best available comprehensive treatment of the subject and is destined to be the standard work for some time to come. ☐

C. Kidson is Professor of Physical Geography and Head of the Department of Geography at the University College of Wales, Aberystwyth.

Amino acids in clinical studies

A. Darbre

Amino Acid Analysis. Edited by J.M. Rattenbury. Pp.380. ISBN UK 0-85312-194-X; ISBN US 0-470-27141-8. (Ellis Horwood/Halsted: 1981.) £27.50, $89.95.

WITH the appearance of the automated ion exchange column method of Spackman, Stein and Moore in 1958, amino acid analysis became one of the most important analytical techniques in biochemistry. Since that date there has been much research effort put into obtaining both faster and more sensitive analyses, and this has enabled the study of proteins, peptides and amino acids to be extended into many fields.

Proteins having unusual properties (e.g. anti-freeze protein) or specialized functions (e.g. receptor proteins on cell membranes) are being continually discovered and isolated, as are peptides and non-protein amino acids with important physiological and pharmacological properties.

This volume consists mainly of the papers given at a symposium, "Amino Acid Analysis in Clinical Chemistry and Medical Research", held in Edinburgh in June 1979. Thus the short title of the book is misleading — this is not a book for the reader whose primary interest is in protein analysis or in methodology. The volume consists of 24 chapters and is divided into four parts. The first, on technical developments, contains 9 chapters which deal with analysis *per se* and review briefly the history of amino acid analysis, fluorimetric detection techniques, gas chromatographic methods, mass spectrometry, derivative spectroscopy and chemiluminescent nitrogen analysis. (The brief contribution on phenylthiohydantoin amino acids, however, does not have a logical place in this book.) The reader who may have accepted at face value widely disseminated statements that "today, it is possible to analyse picomole levels of amino acids in protein hydrolysates in 1h with the automatic loading of up to 80 samples" (p.138), with complete computation and print out of the results to an accuracy of 3 per cent (see p.132), should read the chapters on standards and accuracy (R. P. Ambler) and collaborative trials (A. P. Williams). These should induce in the researcher a much more critical approach to the "print-out" of results obtained from the computing integrator!

The *raison d'être* for this volume lies in the last 15 chapters, which have been divided into separate parts under the headings of amino acid analysis in, respectively, physiological processes, systemic disease and congenital disorders. There is much of interest here, presented in easily readable form, but the emphasis is on results obtained in a physiological and clinical context, and not on the methods used. Thus there are chapters related to protein digestion and absorption (our knowledge here is still very inadequate), the effect of protein quality on plasma amino acid levels in low birthweight babies and plasma amino acids following parenteral nutrition of the newborn, and in chronic renal failure, acute liver failure and alcoholism. The specific analysis of 3-methylhistidine and hydroxyproline as a measure of protein breakdown, and amino acids as neurotransmitters are also discussed. Two contributions give generalized accounts of amino acid analysis in the study of inborn errors of metabolism, whilst others are devoted to homocystinuria, Wilson's disease and spina bifida.

All chapters include adequate references for further reading. But it should be noted that a new word — "exteriorisable" — (p.153) has crept into the English language: this inborn error of grammar should be quickly eliminated. □

A. Darbre is Senior Lecturer in Biochemistry at King's College, University of London.

Synmetals: a new branch to polymerization

Herman Mark

Semiconducting Polymers. By Marian Kryszewski. Pp.710. ISBN 83-01-00818-0. (Polish Scientific Publishers, Warsaw: 1981.) $35.

FOR many years synthetic organic polymers have been of considerable interest and value for their mechanical and thermal properties such as rigidity, strength, elasticity, high softening range and chemical stability. With these properties they have been very useful in a variety of industries, textiles, films, sheets and plastics, for example. Several years ago, however, these materials underwent a surprisingly rapid development as "synmetals", that is, systems which can act as conductors or semiconductors. Their preparation and tailoring for the second application has now grown into a science and technology of considerable proportions.

Marian Kryszewski's *Semiconducting Polymers* is the first comprehensive treatment of this new field. It serves a two-fold purpose: first, it familiarizes the reader briefly with the basic principles of semiconduction, and then it describes how this intriguing property can be obtained with organic polymers.

There are two principles which serve to establish semiconductivity in such systems: the presence of polyconjugated chains and the availability of charge transfer complexes. The largest part of the book is reasonably devoted to the description of polyacetylene because this has been more closely investigated and has already led to semiconductors of wide potential application — f.i. in the construction of new types of photovoltaic cells, pacemakers and thin electrical batteries. Also included in the account of their preparation and behaviour are descriptions of their photoconductivity, magnetic characteristics and catalytic activity.

The author has been through his topic with great assiduity and diligence. For the generally interested reader he has provided a lucid and attractive story; the expert, too, will be grateful to him for the 3,000 or so references which constitute a comprehensive bibliography.

This is a remarkable book and, as the new field grows and unfolds, it may well one day be seen as a classic. □

Herman Mark is Dean Emeritus of the Polytechnic Institute of New York.

Can change damage your mental health?

The US Court of Appeals says that environmental impact statements should cover psychological factors, giving environmental pressure groups a licence for mayhem.

The United States Appeals Court in Washington has put a pistol, perhaps even a bazooka, into the hands of opponents of new developments of any kind. The court has now ruled (see page 179) that electricity cannot be generated at the undamaged reactor at the Three Mile Island site on the Susquehanna River in Pennsylvania until its luckless owner has shown that the mental health of the local population will not as a result be damaged. The decision is important not merely because it may be the straw that breaks the back of Metropolitan Edison but because it can in principle apply to any project caught by the Natural Environmental Policy Act, 1970.

So far, impact statements have been attempts to anticipate physical, biological and social consequences of new developments. In many ways, they have been interesting and even important documents. The impact statement on the Alaskan pipeline may even now be the handiest source of information on the migration of caribou, for example.

Impact statements as they are suffer from a common imbalance. The most tangible and easily anticipated consequences of some new development are covered in great detail. The species of flora and fauna within striking distance of a development site are usually catalogued in detail, as are the volumes of traffic expected on the highway system. (Farseeing developers do their best to recruit the help of the local university in carrying out this kind of work.) The less tangible but usually more important issues raised by new development projects are, perhaps inevitably, given less close attention. While it may be possible to estimate the long-term consequences of a new development for the economic development of a neighbourhood, even that kind of calculation is necessarily shot through with sources of error. And so far, those responsible for preparing impact statements — itself a kind of growth industry — have shrunk from trying to estimate whether a development will make the local population happier. The importance of last week's decision is that it requires not merely the owners of the Three Mile Island nuclear site, but in principle all other managers of public works in the United States, to show that their proposals will not bring psychological damage.

The objective is laudable but the task which it implies is both impossible and, on grounds of principle, irrelevant. What has happened around Three Mile Island since the accident in March 1979 should have given the Appeals Court pause. The population in the neighbourhood of the reactor has understandably been a focus of interest for social scientists seeking evidence of the minor psychological consequences of such an occurrence. Most accounts of these investigations appear to agree that during the immediate crisis, people living within fifteen miles or so of the damaged reactor consumed more sleeping pills than those living further off. Some of these habits persisted for as much as nine months, but Dr Peter Houts of Pennsylvania State University, the author of one of the most through investigations of this kind, says that his latest survey, in October last year, shows no residual measurable consequences of the reactor accident. Other studies, reported by the Kemeny Commission, suggest that at no stage were the signs of stress reported by the local population sufficient in frequency and intensity to qualify as psychiatric illness.

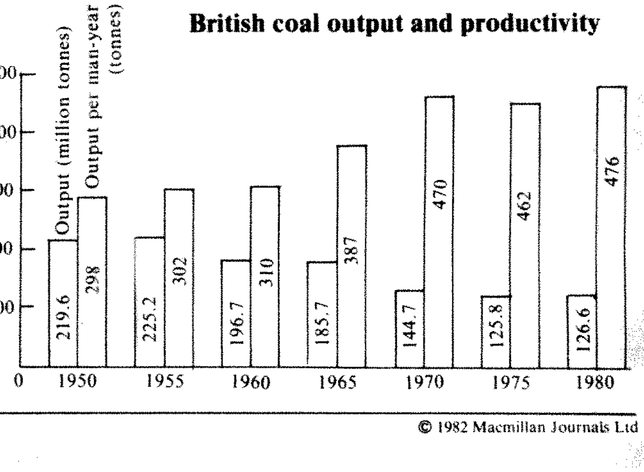
Against this background, it is inconceivable that environmental impact statements purporting to describe the psychological impact of some new project can be more than fanciful fiction. It is just conceivable that, as at Three Mile Island, it might be possible to measure something tangible. But how, in the absence of a range of studies in the neighbourhood of sites capable of generating serious accidents will it be possible to predict the psychological stress caused by some new development? Will the federal government be expected now to sponsor essential baseline investigations of the incidence of minor symptoms of anxiety among people living near, say, Titan missile silos, or projected missile sites as well as nuclear reactors? What is the chance that the results will be statistically significant? And what use will they be to the drafters of future environmental impact statements?

Even if the measurements the court supposes could be made were made, however, they would be irrelevant. Provided that development projects are not so awesome that they topple people over into frank psychiatric illness, the all-important question becomes that of whether there should be a moratorium on all development projects likely to increase the general level of anxiety in the population. Presumably hydroelectric schemes of all kinds would quickly be stopped, however necessary their output of energy. So too would most defence projects and all nuclear projects. The result would be a nonsense, so that the court's decision must be changed. But that will take time. Meanwhile, environmentalists have a licence to do irreparable damage.

Paying the price for coal

The British coal industry, again in crisis, should be either closed or administered logically.

In February 1974, the then Conservative government called a general election in the wake of a damaging strike about pay by British coal miners. The central issue at the election was the government's question "Who governs Britain?" — the elected government or the miners. The rhetorical question was never answered, although Mr Edward Heath, prime minister at the time, was clearly told that it should not thereafter be him. A similar tangle with workers in nationalized industries among whom the coal miners were again conspicuous put paid to the government which succeeded his, in the spring of 1979, and paved the way for the present administration. It is therefore inevitable that Mrs Thatcher and her colleagues should be nervous about the outcome this week of the ballot among the miners, who are being



British coal output and productivity

0028-0836/82/0300177-02$01.00

asked by their leaders to agree that there should be another strike, again over pay, if one should "be necessary". Pollsters and soothsayers guess that, this time, the voting will be so close that there will not be a clear mandate for a strike, in which case the government will claim a victory for good sense and for its policies of the past two years, miners' pay will increase by 9.3 per cent and everybody will forget about the issue until next year. That would be a serious mistake. What the British government should now be asking is whether Britain needs a coal-mining industry, or can afford one.

On strictly economic grounds, the mining of coal in Britain should be stopped. The cost of producing and distributing British coal within the United Kingdom is more than that of importing it from the United States and even from Australia. For several years, the nationalized National Coal Board's chief customers, the nationalized Central Electricity Generating Board and British Steel Corporation, have been muttering about the advantages of importing coal, and did indeed buy 5 million tons of coal from overseas in 1980–81. Given encouragement, these two customers for domestic coal production (which take well over three-quarters of total output) could profitably import more. In reality, they are being pushed in the other direction by the National Coal Board and by the miners, chiefly by being offered British coal at prices well below the average cost of production. The British government provides a modest subsidy to this end, but not nearly enough to make good what the coal board loses on the transactions. Two consequences follow inexorably. By hanging on to its chief domestic customers, the coal board is forced to charge others more than would strictly be necessary. But, even so, the coal board's accounts are perennially in deficit. The British government, although perpetually preaching economic realism, and the coal board are in collusion to make water run uphill.

Although this curious state of affairs has arisen because of the determination of British coal miners not to let production fall still further — it has halved in a quarter of a century — it should have been no surprise. More than a century has passed since W. Stanley Jevons argued in *The Question of Coal* that British industry as a whole was vulnerable to competition from abroad because of its dependence on deep-mined coal, inherently more costly than the coal from thick near-surface deposits such as those in the plains states of North America. (Forgivably, Jevons did not anticipate the phenomenon of Japan, industrially competitive with hardly any indigenous fossil fuel.) The British coal industry, like the more heavily subsidized coal industries of Belgium, France and West Germany, is victim to the geology of all extractive industries. The British coal board would be more competitive if it were more free to concentrate production on those coal fields in which seams are thicker and more accessible, but its employees will not let that happen. The board's plan to shut twenty uneconomic coal mines during 1981 was modified after a series of strikes, and in the event only ten were shut. Given that failure, economic logic would suggest that British users of coal should be encouraged to meet their needs from abroad, and that the British coal-mining industry should find its own presumably shrunken level at which costs and prices are in some kind of balance.

There is no prospect of this happening. For half a century, the politics of coal mining have overridden economics and common sense. In present circumstances, the coal board has a minor point in its arguments that the cost of imported coal is now lower than it would be in normal times because the cost of shipping is depressed by the world recession. The board and the government are, however, united in their belief that the British coal-mining industry is strategically necessary — a hedge against the emergence of an Organization of Coal-Exporting Countries or some other improbable development of that kind. The argument would be more convincing if it were made explicit, and if its implications were followed consistently. First, there is no reason why strategic considerations should require 100 per cent self-sufficiency. Why not 80 per cent, or 70 per cent, or some other proportion of present consumption? Second, if the high cost of domestically produced coal is politically and financially an embarrassment, the British government should become the active sponsor it once promised to be of the only other substantial source of indigenous energy — nuclear power stations. Third, and most immediate, if the case for keeping alive the British coal industry is strategic, should the government continue to insist that the substantial hidden costs of that policy should fall primarily on those who use it? The result is that the coal board has to sell its product at too high a price to unwilling customers, thus ironically undermining the objectives of keeping some kind of coal-mining industry in good shape — and needlessly increasing industrial costs at the same time. The British government, which has enthusiastically embraced its predecessor's policy of charging the international price for oil from the North Sea, should now do the same for coal. Then at least the cost of the present policy would be explicit in the government's accounts and not hidden in those of the coal board.

Ice age or melt-down?

Recent winter mid-latitude weather has been awful. But it is a fluctuation, not a cataclysm.

After a couple of weeks of unexpected but seasonal cold weather in Western Europe and North America, the public rumour mills are grinding out news that there may be another glaciation around the corner. A host of people who should know better, many of them professional earth scientists, have been engaged in grave televised discussions about the chances that a few days of snow and slush either presage the return of the ice sheets (this time without bison and mammoth) or are paradoxical accompaniments of the general increase of atmospheric temperature to be expected from the accumulation of carbon dioxide in the atmosphere. Television interviewers have been visibly discomfited by this apparent assault on common sense, and have usually chosen to leave their audiences with a reminder that the ways of science are incomprehensible, and that if a suitable qualified gentleman has said that it has been devilishly cold because the earth is getting warmer, he must be right.

The truth, of course, is that none of this rambling is relevant to the past weeks' weather, in Western Europe, North America or anywhere else. The meteorology of Western Europe's admittedly wretched weather is easily described and is even familiar. The usual stream of depressions across the Atlantic was diverted from course by an apparently stationary centre of high pressure over Scandinavia. As a result, relatively warm southwesterlies were replaced by cold northeasterly winds. Closely similar stationary high-pressures centres occur most winters inland of the western seaboard of Eurasia, but not always at the same longitude. The intriguing question is why such high-pressure centres should be stationary. The simple answer is that nobody knows. The more complicated answer is that many people are trying to find out. Whether the frequency or durability of such high-pressure centres are positively correlated with the atmospheric concentration of carbon dioxide is plainly an unanswerable question, and will remain so until the mechanism of what the meteorologists call blocking is understood.

So is there no choice but to regard the past few weeks' weather as a statistical fluctuation on the usual pattern? None. Are the climatic consequences of all that extra carbon dioxide still in doubt? Yes. And is there a prospect of being able to walk once more from Britain to France as at the peak of the most recent glaciation 18,000 years ago? No, too little is known. That, when the next season of blizzards (or of droughts) comes round, is the public message that the professionals should seek to put into circulation. It is something of a triumph, for the public understanding of the world we occupy, that people's imaginations have been caught by knowing that there is no way of distinguishing between the present period and one of the earlier Pleistocene interglacials. It serves no purpose to corrupt that state of affairs with over-sharp predictions of what the future holds. One swallow does not make a summer, nor one blizzard a glaciation.

Mental stress given environmental status

Court delays start at Three Mile Island

Washington

In a precedent-setting decision, the US Court of Appeals in Washington has decided not to allow the Metropolitan Edison Company of Pennsylvania to switch on the undamaged power plant at Three Mile Island, near Harrisburg, until it can demonstrate that such a move would not adversely affect the mental health of people living in the area.

The immediate impact of the decision, which reverses a ruling by the Nuclear Regulatory Commission (NRC) that psychological factors do not necessarily have to be taken into account in deciding whether to allow nuclear plants to start operating, will be to delay for several more months the start up of "Unit One" at Three Mile Island. The reactor was undamaged in the accident which occured to its twin, Unit Two, in March 1979, and since then has been considerably modified to improve safety.

The ruling, however, which was made by two of the three members of the appeals court, could have a significantly wider impact. For the first time it means that although the powerful Natural Environmental Policy Act of 1970 does not require psychological factors to be taken into account when the social impact of a federal decision is being assessed, the act can be interpreted as allowing such factors to be included.

The Three Mile Island accident resulted in a small amount of radioactivity being discharged into the environment but no significant extra radiation exposure to individuals, so nobody suffered physical health damage as a result. The principal focus of interest, therefore, has been on the psychological implications of the accident.

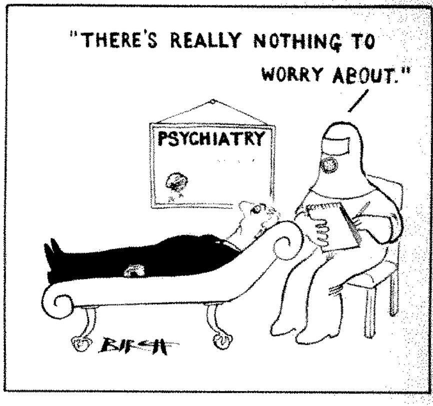
Arguments about the psychological impact of the accident have been continuous since it occurred. Civic leaders warned NRC that thousands of people might be driven from their homes by fear of radiation if krypton gas was allowed to be vented from the crippled plant. Some claimed that "riots" might result as a possible manifestation of the population's nervousness.

Such arguments have, until now, fitted uneasily into the institutional mechanisms set up to cope with the social consequences of major technological actions. Thus when Metropolitan Edison applied to NRC to be allowed to start up the undamaged plant, the commission rejected claims from a local citizens' group, the People Against Nuclear Energy (PANE) of Middletown, Pennsylvania, that such a move would have sufficient psychological effects to make it necessary to take these into account.

The request from PANE had been supported by the members of NRC's own Atomic Safety and Licensing Board — partly on the grounds that taking such factors into account while the licensing decision was being reached could head off later conflict — but was rejected by NRC.

The Appeals Court has now told NRC that it was wrong, and has directed the commissioners to conduct a broad assessment of the effects that starting up Three Mile Island's Unit One will have on "the psychological health of neighbouring residents and on the well-being of surrounding communities". After that, the commission will have to decide whether the National Environmental Policy Act requires a more detailed analysis of the social and environmental impact — possibly including a public hearing — before the decision to restart the undamaged reactor could be taken.

The court's decision was not unanimous. In a strongly-worded dissent, Judge Malcolm Wilkey argued that by establishing psychological stress as a factor which had to be taken into account by NRC, the court was defining "an 'impact' which has never before been considered as covered by the National Environmental Policy Act", a move which, he said, had "enormous consequences".



"THERE'S REALLY NOTHING TO WORRY ABOUT."
PSYCHIATRY

The decision was greeted with gloom at Metropolitan Edison, which had been hoping to start up Unit One within the next few days, and which was depending on revenues the reactor would produce from the sale of electricity to help cover some of the costs of the clean-up at Unit Two which are already threatening to force the utility into bankruptcy.

Predictably, the appeal court's decision was welcomed by members of PANE. The group had argued that the inclusion of psychological factors should be part of the responsibility of licensing institutions to protect the public health and safety, as defined in the Atomic Energy Act of 1954.

David Dickson

European nuclear safety policy attacked

Brussels

Has the Euratom treaty, which binds the European Community's nuclear energy policies together, been properly interpreted and applied? A lengthy report by the leading Belgian socialist member of the European Parliament, Anne-Marie Lizin, suggests not and attacks the lack of progress towards achieving the aim of a European zone of unified nuclear safety standards.

Lizin's report was the subject of heated debate in the European Parliament's Committee on Research and Energy, where 91 amendments were proposed. Having looked in detail at EEC's activities in the fields of radiation protection, reactor safety, decommissioning, safety of the fuel cycle and the national nuclear inspection services, Lizin concluded that the Euratom treaty is outdated and vague and that the European Commission has made too little use of its powers under the treaty.

Lizin alleges that when the treaty was first drawn up, more than 20 years ago, too little consideration was given in the nuclear energy development plans to reactor safety and worker protection. Since then, the member states have proved reluctant to provide the European Commission with effective consultation procedures for all decisions concerning the location and operation of nuclear power stations. In Lizin's native country, Belgium, the licence to build a nuclear power station is granted independently of the initial safety analysis, and given the fact that too many nuclear power stations are built close to frontiers or use shared river systems, the report complains that there is too little consultation on measures to protect workers and local populations.

The report goes on to say that although the Community has been efficient at listing methodologies, standards and safety criteria, work on listing similarities and differences among the member states has been too slow and the Community has yet to go on to the third stage of putting forward its own regulations. This work has largely been left to other international bodies such as the Organization for Economic Cooperation and Development and the International Atomic Energy Agency. Lizin attributes particular importance to the Super-Sara project but calls for more studies into the safety of gas-cooled and heavy water reactors. The problems of waste management and recycling are given particular attention because the report considers that this field requires intense supervision by an independent public

0028-0836/82/030179-02$01.00

authority.

The role of the Community in the decommissioning of nuclear plants is reassessed. Lizin suggests that EEC's financial instruments, such as the regional fund, could help and that electricity companies or utilities should be asked to pass on decommissioning costs directly to the consumer. Lizin's lengthy list of recommendations also tries to sting the Commission into providing stricter surveillance of the work carried out by national supervisory authorities.

Undoubtedly something akin to the steel crisis, which made many realize the immense emergency powers invested in the Commission by the treaty of the European Steel and Coal Community, will be necessary to bring the strength of the Euratom treaty into play. But Lizin's awareness of this possibility has been heightened by the controversy surrounding the enlargement of the French nuclear power site at Chooz, a few kilometres from the border with Belgium. Notwithstanding local and national protests from Belgians, and the French socialist party's preelection promises, the French Prime Minister, François Mitterrand, still seems set on increasing the number of nuclear reactors there. **Jasper Becker**

French colloquium

Science passion

Paris

The great national colloquium last week on the state of science in France was sometimes like a high mass, sometimes more like a giant committee meeting. And although, after six months preparation, the colloquium (which was strictly advisory) displayed few radical disagreements, the test of its success will come only with the publication of a new law to be put to the French Parliament in the next few weeks.

The theme running through the four-day meeting was uplifiting. M. Jean-Pierre Chevènement, Minister of State for Science and Technology, told the closing session that "the highest authorities of the state" have decided that scientific research is vital "for the successful change and future of our country". The highest authority himself, President François Mitterrand, had set the ball rolling with a declaration that "only a gigantic effort in research" will allow France to master its technology and thus make certain of its independence.

Both the President and his Prime Minister, M. Pierre Mauroy, were, however, anxious that the forthcoming expansion of science in France should follow the "wishes of society". Mauroy also wishes to reintegrate science into the wider culture of France from which he thinks it has been too long isolated. But to Chevènement himself, "science is a passion and France needs passion". Since the election in May 1981, he said, hostility to science and technology had been turned back.

Inevitably, on what could not fail to be a patriotic occasion, the minister also developed his theme that French science must increasingly be seen to be French. He promised data banks and scientific books in French and that the great international science journals would be translated. Meanwhile, the French cabinet has agreed that the volume of government spending on science should increase by 17.8 per cent a year over the next three years and that private industry should be encouraged to increase research and development investment by 8 per cent a year. This should bring French research and development expenditure to 2.5 per cent of the Gross National Product by 1985. Jobs will be created at the rate of 4.5 per cent a year over the same period.

All this has given the minister for science more spending power and more influence. He already controls almost all the forward-looking agencies of the Ministry of Industry and is thought to be lobbying for the merger of that ministry with his own.

Chevènement is nothing if not visionary and ambitious. The politics of health depend on research, he said, as do the politics of labour and employment. Science and technology could increase French independence while the creation of a "French pattern" for the organization of science could be a model in fields other than science and technology.

The new law, to be prepared in the next few weeks, will define new contracts of employment for researchers, set financial targets for institutions and set the "French pattern" of research for 1983–85. The expectations are that the law will leave most institutions unchanged except for the introduction of union representatives on certain committees. But the law will provide for new small-scale technical enterprises and regional centres of development in certain fields.

Under the promised arrangements, there is to a new high-level advisory council together with regional advisory committees. Social science, Chevènement said, needs to be impelled forward. And what is it all for? "To spread knowledge, to push back anti-scientific prejudice, to assure the progress of the sciences of man and society, to maintain or re-establish French." **Robert Walgate**

River of words, mountain of paper

Paris

There were no *bateaux mouches*, the "firefly boats" with glass roofs, on the Seine last week. The river was a torrent almost filling the arches of the bridges and menacing the city. It was much the same with *la vague Chevènement* (the Chevènement wave) as one paper dubbed it. The Minister of State for Science and Technology, Jean-Pierre Chevènement had organized all the tributaries of science in France, and in its overseas territories and departments, to converge on Paris.

The organizers of this national colloquium for science and technology estimated that there had been nearly 200,000 pages of written contributions to the colloquium and its regional predecessors (held in October and November last year). This is almost a page for each of the 280,000–300,000 scientists and technologists in France. There were almost 10,000 individual documents, all of them arguing over which points needed to be changed, modified or amplified in the politics and organization of science and technology.

A torrent of words, a torrent of ideas and clearly an historic moment for French science: Chevènement certainly hopes so, for his ambitions go beyond science and technology. Last week, he did his best to take strict control of the colloquium. The 200,000 pages were reduced to 950 reviews, written largely by people chosen by the ministry. Then 200 of these reviews were placed before 12 colloquium committees, also hand-picked. And the committees reduced these to 40-page summaries, which were then discussed.

Neither colloquium nor committees were empowered to take decisions. And even the most apparently practical committee, that on finance, was required to discuss only principles: such sordid matters as actual figures and percentages were set aside.

Nevertheless, there had been attempts to make the composition of the committees representative. There were more than 100 people in each committee, making 1,500 in all, drawn from three categories — 200 were directly involved in preparing the national colloquium and the regional summaries, 500 were from institutions, such as industries, the principal science funding bodies, ministries, universities and unions. **Robert Walgate**

0028-0836/82/030180-02$01.00

University of London

All change now

Of the central functions of the University of London, only the students' union is wholeheartedly applauded for its efficiency in the final report of the Committee on Academic Organization, published last week. The committee, set up in March 1980, was originally intended to recommend a new organization for the university. After last summer's financial cuts, the committee's terms of reference were redrafted to exclude the main teaching institutions.

One conspicuous recommendation in the report is that the university's Nuclear Reactor Centre (at Silwood Park in Berkshire) should either be closed or, preferably, transferred to Imperial College. The committee says that the centre's chief function is research, and that it should be possible for the centre to find at least half its total cost of £220,000 a year in research grants.

Among other recommendations are the continuation of the Marine Biological Station on the Clyde (administered jointly with the University of Glasgow) and the Institute of Archaeology. The report also suggests that the university could save £100,000 a year by closing its Botanical Supply Unit.

The most serious criticisms are of the central administrative machinery. The court department (which shares out the university's public grant) is too secretive, and urgently in need of computer techniques, the examinations department is overstaffed and the university's network of academic committees has outlived the time when "the need and even the opportunity for taking genuine decisions . . . has ebbed away".

In general, the committee comes down in favour of a university in which its colleges function autonomously, taking more control from the centre. But it is also against the proposal that University College should be financed separately.

These proposals are for change within the existing framework. The committees set up last September to recommend new patterns of teaching in broad subject areas appear to be following an orthogonal track. The first of their reports, published this week and dealing with the physical sciences, starts from the assumption that only large departments can be successful in research.

Most of its recommendations are that the teaching of science subjects should continue at four colleges (Imperial, King's, Queen Mary and University) and at most one other site within the university. A total of 58 academic posts in the physical sciences would be lost.

Both sets of recommendations will excite opposition. In each case, the next step is discussion by the university's academic committees and the senate.

AT&T pact hits snag

Washington

A federal judge in Washington has injected an element of uncertainty into plans to reorganize the giant American Telephone and Telegraph Company (AT&T) by announcing that, although the federal government and the company have agreed on terms for suspending the anti-trust suit filed by the Department of Justice, he is unwilling to dismiss the suit without further study of the agreement.

The Reagan Administration announced the settlement with AT&T, the largest company in the world, on 8 January. Under the terms of the agreement, AT&T has agreed to sell off 22 local telephone companies, with assets worth around $80,000 million, in return for being allowed to enter other fields of telecommunications, such as electronic data processing, from which it had previously been excluded.

US District Court Judge Harold H. Greene, who has been hearing evidence in the government's case against the company since 1978, said last Tuesday that he was "delighted that a settlement had been reached". At the same time, however, apparently concerned at the secrecy and speed of the negotiations between the company and the Justice Department, he has refused to dismiss the case without further scrutiny of the terms of the agreement. Judge Greene said that the case was "too important to the judicial process, to the public and to the country" to be closed as a result of a "haphazard process".

Judge Greene's actions are in line with a law passed by Congress in 1974 giving the public an opportunity to comment on anti-trust agreements between the government and a private company before these are concluded. The law was passed in partial protest at the secrecy which had surrounded negotiations between the government and AT&T leading to a previous consent agreement in 1956.

David Dickson

Polish universities

Wings clipped

Polish universities will resume work by mid-February, according to a communiqué issued on 10 January by the ruling Military Council of National Self-Defence. Tertiary education establishments, it says, will function "taking into account regulations deriving from the decrees on the state of martial law" and special rules have been laid down governing the running of full-time courses during the state of emergency. Moreover, resumption of university activities each term will be approved on the basis of recommendations from the Provincial Defence Committee — on the basis of how, in the previous term, the university complied with the emergency regulations.

The communiqué effectively abrogates the liberalization of academic life which followed the signing of the Gdansk accords in August 1980. In particular: academic and scholarly work is to be censored. The abolition of the censorship of learned publications was one of the first demands of the Academy of Sciences and the universities in autumn 1980, and was embodied in the censorship law which came into force on 1 October 1981.

University autonomy concerning syllabuses will be restricted. All students will have to attend courses in two foreign languages. This means a return to compulsory Russian, which was abolished by the Lodz accords that ended the students' sit-in last February. New courses and subjects will require ministerial approval, which will presumably not be forthcoming for courses reflecting the "plurality of outlook" promised at Lodz.

University rectors will now be responsible for maintaining order on campus and in students' hostels. No student may remain on campus outside tuition and library hours, and all staff must leave as soon as their working day is over. This reverses the spirit of the Lodz accords which left law and order on university premises firmly to the university authorities and banned civil police from campuses.

Attendance at lectures and classes will be obligatory, and absence without sufficient excuse may result in expulsion. Students may also be expelled for infringing Article 46 of the decree of martial law, which bans union activity and the organization of strikes and protests. Special classes are to be held at the start of the new session, explaining to the students the demands of martial law, and particularly of the new oath of loyalty.

University senates and faculty councils will be reduced to advisory status, and will have a composition "determined by the regulations of the law in force". This provision is ambiguous, since the communiqué also says that the universities will operate on the basis of the 1958 law on tertiary education — which would mean an end to the 30 per cent student participation in senates and faculty councils introduced after Lodz.

The rectors are instructed to appoint special plenipotentiaries to deal with the welfare problems formerly the province of students' unions and self-governance bodies, and will have the right to order their employees to carry out tasks hitherto not considered part of their duties. They may also order students to carry out "socially useful work" for the university or the national economy.

During the past year, all Polish university and technical college rectors have been democratically elected — except in Radom Engineering College, where an attempt to impose a rector who was not so

0028-0836/82/030181-02$01.00

Gentle Polish protest

The Royal Society and the British Academy last week sent a message of "sympathy and support" to the Polish Academy of Sciences. The message, signed by the presidents of the two academies, regrets "the interruption of normal relationships" between Britain and Poland and hopes "that they will soon be resumed". The message is to be sent to other academies which are members of the International Academic Union and the International Council of Scientific Unions.

elected led to nationwide student protests and a virtual shut-down of academic life. At least three rectors have been reported to have been interned: Dr Henryk Samsonowicz of Warsaw, Dr Jozef Gierowski of the Jagiellonian University of Krakow and chairman of the unofficial rectors' conference and Dr Janusz Ziolkowski of Poznan. How far other rectors will comply with regulations which seem aimed at reducing them simply to disciplinarians is unknown. **Vera Rich**

Finnish–Soviet research

Arctic collaboration

A new Finnish–Soviet Arctic research committee will meet for the first time next month, to work out a new joint programme for the development of the Soviet Arctic. The formation of the committee comes at a critical point in Finnish–Soviet relations: the retirement from politics of President Urno Kekkonen, the chief architect of Finland's policy of neutrality coupled with close economic cooperation with the Soviets.

Earlier this month, Mr Ahti Karjalainen, head of the Bank of Finland and chairman of the Finnish–Soviet economic committee, was in Moscow for talks on future deals including an icebreaker to be built for the Soviets in a Finnish shipyard and a contract, worth up to £125 million, for the third stage of the paper mills and urban development being built by Finnish expertise at Svetogorsk, just inside the Soviet frontier.

The new Arctic research committee, though essentially a research and development body, will to a certain extent overlap the economic agreements. For example, Mr Karjalainen has been discussing a joint off-shore geological survey for oil and gas in the Barents Sea. Accordingly, one of the major joint research projects on the agenda of the new committee will be devising the technology necessary to construct an oil and gas drilling rig on an ice floe.

Finland has considerable expertise to offer its partner. One participant in the new committee is the University of Oulu, which under the recent policy of decentralized and regionalized higher education runs a programme of research into the economic and development problems of northern Finland, much of which can be immediately applied to work in Arctic Siberia. In particular, Oulu will contribute a new technique for surveying terrain with up to 2 metres of snow cover. Oulu is also the seat of the Research Council for Arctic Medicine, and has a special laboratory for the study of the physiological hazards of work in a cold climate.

The main workload of the cooperation will be undertaken by the Technical Research Centre (Valtion Tekniken Tutkimuskestus, VTT), a government-sponsored body whose mandate includes research (at cost price) on behalf of those who wish to exploit the results but who do not have the facilities to carry out basic investigations themselves. VTT has 31 laboratories (26 in the Helsinki area, 3 in Tampere and 2 in Oulu). Fifteen of these laboratories will be involved in the cooperation programme, and it is estimated that participation will allow VTT to double its research staff in the next few years. Finland, with a population of 4.7 million, has no less than 18 universities, an escalation from two over the past 25 years resulting from "regionalization" policies, and employment for graduates who wish to remain within the Finnish academic/research structure is a perennial problem. A strong swing of public opinion away from science in the mid-1970s was by no means fully reversed by the then President Kekkonen's call for a reassessment of research and development investments in his New Year message to the nation in 1979. (This was the first time that science had been officially boosted since 1964.)

The new Soviet–Finnish Arctic research programme, the details of which will be worked out next month, is already being regarded by Finnish economists and business experts as a major shot in the arm. Its effect on graduate employment should prove equally beneficial. **Vera Rich**

Deep-sea mining

United States re-think

Washington

United States policy on deep-sea mining is again in the melting pot. The recent discovery of large ocean-bed deposits of polymetallic sulphides in various parts of the world has significantly raised the stakes in the continuing disputes over what form of international regulation should be introduced to deep-sea mining.

In the United States, plans are already being discussed to amend the Deep Sea Mining Act, passed by Congress only two years ago. The act provides a mechanism for issuing licences to US companies wishing to collect manganese nodules from the sea bed but could, as it now stands, exclude retrieval of the sulphides.

A different problem exists with the UN Law of the Sea Treaty, negotiations on which are nearing completion after eight years. The current draft of the law is sufficiently flexible to include polymetallic sulphides but US mining companies, backed by the State Department, are concerned that in its present form with no explicit attention to the sulphides, the whole question could be put on hold indefinitely.

Although chemical geologists have long predicted the existence of sulphide deposits associated with rift phenomena on the ocean bed, the first discovery was made as late as 1978 on the sea floor of the East Pacific Rise, near the coast of Mexico. Since then, several similar sites have been discovered off the Pacific coast of the United States, for example in the Juan de Fuca ridge off the state of Oregon. The minerals involved include cobalt, manganese, platinum, zinc and tin.

The most dramatic discovery so far, however, was announced last October by scientists from the National Oceanographic and Atmospheric Administration (NOAA) of the US Department of Commerce. The NOAA geologists have found several mineralized zones between the Galapagos Islands and Ecuador, in the Pacific, which they estimate to contain 25 million tons of polymetallic sulphides. The high concentration of copper and iron in the sulphides is calculated at about 10 per cent each. Also present are lead, molybdenum, vanadium and zinc (0.1 per cent each), and silver and tin (0.3 per cent), with trace amounts of cadmium, gold and platinum.

Whether the minerals in the sulphide deposits are sufficiently accessible to be worth mining is yet to be determined. The NOAA geologists estimate that the total value of the metals in the latest find is about $3,000 million, and new mining and processing technqiues would have to be developed to retrieve them.

Several large companies such as the consortium headed by Lockheed Missiles and Space, are already turning their attention to the commercial potential of the sulphides and are carrying out preliminary exploratory surveys.

Whatever is discovered, mining of the sulphides will inevitably be affected by the negotiations that have taken place within the United Nations since the resources of the high seas were declared, by an unanimous resolution passed in 1970, to form part of the "common heritage of mankind", whose exploitation should be regulated in a way that would result in the most equitable distribution of benefits.

Deposits relatively close to national coast lines are unlikely to be covered by international legislation. In line with provisions contained in the draft Law of the Sea, the US Congress is expected soon to begin debating a bill which would create a 200-mile exclusive economic zone off the US coast. The discovery of the polymetallic sulphides will add to the political attractions of this bill, since several of the known deposits — such as those in the Juan de Fuca ridge — lie wholly or partially within this distance of the shore. And if the bill passes, as seems likely given the expected support of the Administration, the companies could begin mining the

0028-0836/82/030182-02$01.00

deposits free of international regulation.

The deeper deposits, such as those off the Galapagos Islands, will create more of a problem. The deep sea mining bill passed by Congress two years ago was designed to provide US mining companies with certain rights that would have to be recognized in so-called "grandfather clauses" in any international treaty, since the latter would require ratification by the US Senate.

This law would require amendment in several places. For example, "hard mineral resources" are defined as any deposit or accretion of "nodules" lying "on, or just below, the surface of the deep sea-bed". Similarly the deep sea-bed is defined as including the subsoil "to a depth of 10 metres", while polymetallic sulphide mineral deposits may extend considerably further.

State Department officials are confident that, with the amendment of certain key definitional provisions, the act can be extended to cover the sulphides. There is much less confidence about the implications of the Law of the Sea negotiations, which Mr Otho Eskin of the department's Office of Oceans Law and Policy says raises "a very serious question".

Accepting that fundamental changes are unlikely to be agreed by the negotiators when they meet again in New York in March, and that a treaty in some form is likely to be adopted by the end of the year, the United States has two main alternatives. Either it could sign the treaty (which would be taken as a symbolic victory by the developing countries, for whom the treaty represents the first concrete mainifestation of the "New International Economic Order"); or it could refuse to sign (which could jeopardize the chances of United States-based mining consortia obtaining the necessary loans from the multinational banks).

David Dickson

Indian agriculture

Cattle go West

Bombay

India's ambitious programme of crossbreeding its cows with foreign bulls is endangering the country's agriculture by creating a shortage of draught animal power — the mainstay of farming and rural transport in India. This is the finding of a survey covering the cross-breeding programme in 18 of the 22 Indian states carried out by the Bombay-based All-India Agriculture and Cow Protection Society (AIACPS) founded by Mahatma Gandhi 40 years ago.

A five-member team of veterinarians headed by Dr M. Y. Mangrulekar contacted over 1,600 cattle breeders and government crossbreeding farms for the survey. Their report just published says that the craze for "westernization" of Indian cows has resulted in the neglect of indigenous milch strains of cattle and has led to shortage of good, sturdy bulls for farming operations.

The survey has revealed that exotic crossbreeding has mostly produced bullocks which are uneconomical. The exotic animals need special grade grass and oil cakefeeds and are unsuitable for the rigours of Indian agriculture: they get easily tired and are unable to walk in the sun or plough in wet fields, unlike the docile native bulls which live on paddy straw and are at ease in dry and irrigated fields. More importantly, the exotic crossbred males have no hump and the traditional ploughs do not fit on them. Thus the crossbred bullocks have been left to starve and die or been sent straight to the slaughter house. The AIACPS report says the crossbreeding programme, mostly financed by international agencies, is actually preparing India to become the world's leading exporter of beef to the meat hungry West. The slaughter of male calves is leading to a shortage of bullocks particularly in Bihar state where, the report says, thefts of bullocks are increasing.

In states such as Karnataka, crossbreeding has been in vogue since the 1950s but other states have taken to crossbreeding in the past two decades and the programme was vastly expanded in the early 1970s under the World Bank financed "Operation (milk) Flood". According to the survey, the high pitched crossbreeding programme is weaning the countryside away from indigenous cattle in favour of Holstein–Friesians, Jerseys and Red Danes, and good Indian breeds are being replaced with unproductive crossbreeds.

The programme has led to the import of bulls, semen, vaccines and insemination equipment but has failed to increase milk production. The hybrid cows after second calving yield less milk than the high-yielding native breeds such as Kankrej, Sahiwal, Gir and Haryana. The survey also revealed that exotic crossbreeds are more susceptible to disease than native stocks, which has led to increased import of vaccines.

However, government officials maintain that the survey findings are at variance with their own evaluation. According to Dr R.M. Acharya, deputy director general of the Indian Council of Agricultural Research, Indian cows are not being westernized wholesale. "Only five per cent of the cattle population is exotic", he says and, the humpless crossbred bullocks are gradually becoming adapted to Indian conditions and their number in farming operations is steadily increasing. According to Dr Acharya the crossbreeding is not new to India where all the military farms have been using exotic breeds for several decades. While India has indeed some good breeds, according to Dr Acharya, only a small per cent of them are really high milk yielders. Despite the controversy officials maintain there is no alternative to exotic cross-breeding for increasing India's milk production, which is currently estimated to be 23 million tonnes annually.

K.S. Jayaraman

Bridging the Indian gap

New Delhi

Mrs Indira Gandhi, the Prime Minister, announed last week a substantial increase of support for science and technology. The increase will amount to more than 50 per cent in this next five years. Mrs Gandhi, always sympathetic to science, has accepted a proposal put to her by Dr M. S. Swaminathan which is intended to strengthen government and university laboratories and to improve the quality of research.

Two new technology boards set up by the Indian government could ease the problem of high unemployment among India's scientific and technical personnel and give a new thrust to biotechnology research in the country.

A National Science and Technology Entrepreneurship Board is to be set up which will seek institutional credit for the 300,000 such unemployed persons to enable them to set up self-employed units. Surveys will be conducted to identify the areas in the country with development potential requiring scientific and technical support.

While some areas have a surplus in scientific and technical manpower (mainly due to unemployed polytechnic graduates or postgraduates) other areas are experiencing critical shortages. For instance, although there are about 4,000 vacancies for teachers in polytechnics in the country, suitable candidates are not available.

The Indian government has also decided to set up a biotechnology board to coordinate the functioning of biotechnology organizations in the country. Its purpose will be to utilize new concepts in biotechnology in agriculture, industry and medicine.

Mrs Gandhi said at the National Science Congress, India's biggest annual gathering of scientists, held in the southern city of Mysore on 3 January, that biotechnology was a frontier area of science, and that the country must take advantage of the latest technologies which could enable India to bridge the intermediate stages.

CORRESPONDENCE

Referees unmasked?

SIR — The present climate of open decision-making in science has been reflected in the printing of signed editorials in *British Medical Journal* (3 October 1981). Surely now is the time to consider alternatives to the traditional policy of anonymity for the referees of learned journals.

The problems which can arise from such a policy have disturbed authors for many years. Recently (*Nature* 25 June 1981, p.608), it has been suggested that the disclosure of the names of the referees to authors would avoid corruption and injustices. The alternative, that the names of authors and institutions be withheld from referees (*Nature* 30 July 1981, p.402), has obvious flaws and double-blind evaluation (*Nature* 17 September 1981, p.293) is unlikely to be attained.

The publication of the names of the referees would give recognition to their responsibility and we feel would lead to an improvement in the standard of published work. At best, a referee can make a valuable contribution to a manuscript, which deserves open acknowledgement in the published paper. Conversely the cursory examination of research work has resulted in the growth in number of papers of dubious merit, despite editorial vigilance. Responsibility for the appearance of such publications should be shared by the referees and their names no longer concealed.

Migration fund?

SIR — What practical steps are we going to take to aid our Russian colleagues who are not allowed to leave their country (see letter from Dikii *et al., Nature* 24/31 December 1981, p.688)? Perhaps we should look more closely at why the Soviet government refuses to let them leave; one feels that there must be some governmental reason for the actions that are taken — it cannot, one hopes, be simply a whim of some highly placed individual.

The Soviet government could argue that it has invested heavily in the education of scientists and cannot afford to waste this investment. But the response to an application to emigrate is the withdrawal of scientific employment and the investment is lost anyway. Perhaps the Soviet government sees the use of this scientific education in another country as a double loss, and opts for what it sees as the better of two bad choices.

Interested governments, involved in scientific migrations, might press UNESCO or some similar body (the International Council of Scientific Unions perhaps) to set up a "Migrant Scientists Fund". This hard currency fund would be used to alleviate some of the injustices caused by scientific migration. For example, a country which loses a scientist could receive monetary compensation; the country to which he goes, which at the moment receives a gift of all that expensive education and training, would pay into the fund. This would benefit many countries, in particular the poorer countries which scientists tend to leave, and should prove no hardship to the rich countries to which they go. New Zealand attracts qualified people, but also loses quite a number; on balance we would probably be drawing from the fund. Australia would contribute.

In the case of the Soviet Union the flow is essentially one way, immigration to the country is on a very small scale. The fund could recompense the Soviet government for its lost educational investment and this might be a welcome source of hard currency. Countries which wish to encourage the movement of scientists could actually donate to the fund.

Vide the Latin

SIR — In the leading article, page 389 in your issue of 3 December 1981, entitled "Tolerance but not quarter for creationists", it is asserted that "creationism is not a part of science but an alternative to it".

As the word science is derived from the Latin *scire*, to know, would it not have been nearer the truth to apply this statement to the theory of evolution? While making no claim to vast knowledge of things existing, as I consider such known things as the cochlea, or the lens of the eye, or three-dimensional perception, I find creationism truly essential to science. A great mind expressed this in *Romans* Ch. 1 v. 20:- "The invisible things of God from the creation of the world are clearly seen, being understood by the things that are made, even his eternal power and Godhead."

D.H.T. CONWAY

Weymouth, Dorset, UK

Areas of neglect

SIR — I have been following with great and increasing interest the profound cogitations on creationism in your respected columns.

However, it is a pity that these discussions have been restricted to a particular field of biology. Surely there are many other sciences that need a thorough overhaul to put them into agreement with divine revelation. Take astronomy for example. It is high time that the godless Newtonian theories should be expelled and the Earth returned to its lawful place at the centre of the Universe.

Another science that is singularly deficient is psychology. Modern textbooks never mention the well-documented scientific facts of manipulation of the human mind by devils. Surely some enlightened state administrators should provide the necessary funds for an experimental investigation of these important phenomena. In this respect we have fallen far behind what was known in the Middle Ages, when at least a number of practical and efficient methods were in use for dealing with Satanic influences.

As a final example one could cite acoustics. The most important application of this branch of physics — the demolition of city walls by sound waves — is no longer a fashionable subject of study, although new findings in the field of surface acoustic waves could provide a solution to this problem. It is a sad reflection on the state of present-day science that students never hear of it, except through a well-known negro spiritual.

DNA and Europe

SIR — The article by Jasper Becker on the EEC safety dispute concerning recombinant DNA (*Nature* 24/31 December 1981, p.686) gives a quite correct picture of the situation. But Jasper Becker states that the socialists are in favour of a community directive. This is not quite correct. The socialist group in the European parliament has never voted on this question. Only the socialist members of the environment committee have given their opinion. Other members of the group, like me, have a different position for a multitude of reasons. In my view, only industrial and agricultural applications of recombinant DNA work should be regulated at an EEC level.

Brief encounter

SIR — In your summary "Hoyle on Evolution" (*Nature* 12 November 1981, p.105) you cite Hoyle as saying that for higher life forms to have emerged by chance is comparable to the chance that a tornado sweeping through a junk-yard will assemble the material into a Boeing 747.

This reminds me of a debate I had some years ago with Dr Douane Gish of the San Diego Institute of Creation Research. The occasion was a symposium in Utrecht organized by the Evangelische Omroep, the Dutch Evangelical Broadcasting Company. This company broadcasts the creationist message for several hours per week to Dutch audiences via television and radio. At the symposium in Utrecht I defended the theory of biological evolution, and Dr Gish defended the biological aspects of creationism. During the discussion Dr Gish remarked that the chance that amino acids would spontaneously form biologically active protein molecules was practically zero. I then said: "Dr Gish, if somebody had asked me on the day of my birth to calculate the chance that one day I would have a debate in Utrecht with Dr Gish from San Diego, I would have answered that this chance was practically zero. Am I therefore to understand that you are not Dr Gish from San Diego?" But my opponent had the perfect answer to that one. He said: "I am not here by chance, I was invited!"

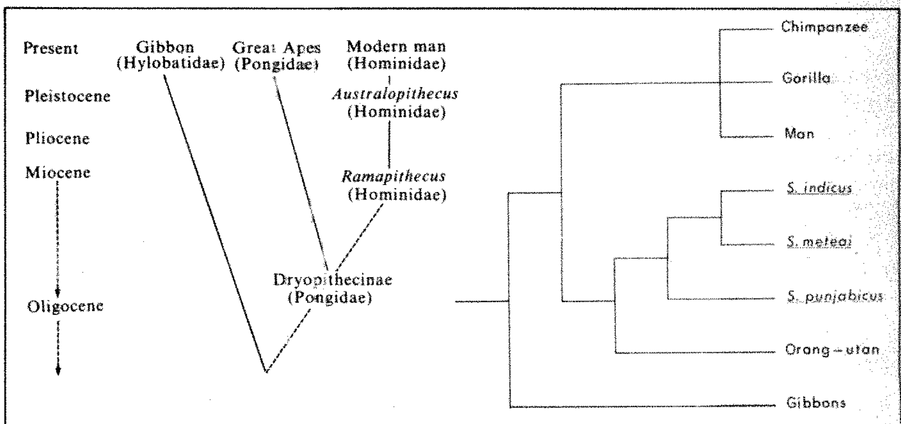
Hominoid evolution

from Peter Andrews



The figure on the left shows the traditional phylogeny of the Hominoidea, with the Great Apes (including chimpanzees, gorilla and orang-utan) separate from the human lineage: the pongids and the hominids. The hominids generally include Pleistocene fossil australopithecines and *Ramapithecus* from the Miocene. The pongids include the living Great Apes and the fossil dryopithecines from the Miocene. The cladogram on the right shows the relationships among the Hominoidea that are proposed here. The Great Apes are split between the orang-utan on the one hand and chimpanzee and gorilla on the other. *Ramapithecus* (= *Sivapithecus*) is held to be related more closely to the orang-utan than to man, chimpanzee and gorilla, and cannot be considered to be a direct human ancestor. One of the consequences of this is that the presence of *Sivapithecus* in deposits 8–12 Myr old suggests a divergence of time of 11–12 Myr for the orang-utan. The divergence of the African apes and man would therefore have been later than this and probably around 6–7 Myr.

In the debate over human origins it has become the traditional view that *Ramapithecus* is the earliest known hominid. Set against this is the opinion, held by a minority, that *Ramapithecus* is more closely related to the orang-utan and is not thus directly connected with the evolutionary line leading to humans. The latter view receives fresh support in this issue of *Nature* (p.232) with the description of a new skull of *Sivapithecus* from Pakistan by David Pilbeam. The specimen is by far the most complete *Sivapithecus* yet found, and it provides information that was previously either unknown or based on reconstructions from less complete material. It will be examined here in relation to two important issues — the position of the orang-utan in relation to other living hominoids and the relevance of fossil primates, in particular *Sivapithecus* and *Ramapithecus*, to hominoid evolution.

The relationships of the living hominoid primates — apes and man — have been greatly clarified by the biomolecular work initiated nearly twenty years ago by Morris Goodman. Three cladogenic events in hominoid evolution have been recognized: the divergence of the gibbon from the common hominoid stock; the subsequent divergence of the orang-utan from the Great Apes and man stock; and the most recent divergence between man and the African apes. As well as defining the sequence of events, molecular anthropology has also been used to date these events, using the so-called 'molecular clock'. Many uses of the clock have been naive, but present estimates for the three events are: gibbon divergence 12 ± 3 Myr; orang-utan divergence 10 ± 3 Myr; and man - African ape divergence 6 ± 3 Myr (Andrews and Cronin, in preparation).

Two consequences arise from these results. First, there is no 'missing link' between apes and man. Man and African apes share a common ancestor, and the man–chimpanzee–gorilla clade shares a common ancestor with the orang-utan. The similarities in grade (mostly from shared primitive characters) between the orang-utan and the African apes means that they are superficially similar and that their ancestral states would also be rather similar. They would therefore be correspondingly hard to identify in the fossil record, and a fossil like *Ramapithecus* might have similarities with either or both. Second, the molecular evidence suggests that the cladogenic events in hominoid evolution occurred later than many palaeontologists have expected. With *Ramapithecus* and *Sivapithecus* thought to be alive between 8 and 12 Myr ago, for example, the fossil taxa would appear to have arisen too early to be ancestral to humans.

The relationships of *Ramapithecus* and *Sivapithecus* can now be examined in more detail to see where their affinities lie. It is becoming apparent that the differences between the two genera are not as great as had formerly been thought. Greenfield (*Am. J. phys. Anthrop.* **50**, 527; 1979) recently proposed that *Ramapithecus* is the same as *Sivapithecus*, and although his systematic procedure is suspect, there is a very high degree of similarity between *Sivapithecus* and *Ramapithecus*. Kay (*Int. J. Primat.*, in the press) has now made a much better case and suggests that *Ramapithecus punjabicus* become *Sivapithecus sivalensis*. Another alternative, which I prefer, is to retain *punjabicus* as a species of *Sivapithecus*. Therefore, in considering the relationships of what was formerly *Ramapithecus* or *Sivapithecus*, the whole complex of *Sivapithecus* species must be considered. At the most conservative estimate there are at least four species of *Sivapithecus* found from 8 to 12 Myr and occurring from Greece and Turkey in the west to southern China in the east.

The specimen of *Sivapithecus* described in this issue of *Nature* is an adult *Sivapithecus indicus* with large parts of the face and palate preserved. It was badly broken when it was found, and Horace French and Rizwana Raza of Yale University have done a magnificent job in restoring it to its present condition. The specimen is the outcome of years of painstaking collecting in Pakistan by the Yale research project, directed by David Pilbeam, now at Harvard, and S.M.I. Shah in Pakistan.

Pilbeam has been very cautious in his assessment of the similarities his new specimen shows with the orang-utan. I will be less cautious and will list some of them: orbits higher than broad, poor development of the supra-orbital torus, narrow interorbital distance, smooth and unstepped floor of the nasal cavity, large zygomatic foramina set above the lower rim of the orbit, extremely small incisive foramina, narrow and slit-like palatine foramina, thick enamel and low cusp

0028-0836/82/030185-02$01.00

profile on the molars and very large incisors in comparison with the lateral incisors. All these characters are present on the *S. indicus* skull, and some at least are known to be present on other species such as *Sivapithecus meteai* and *Sivapithecus punjabicus*. They are all interpreted as being derived from the primitive hominoid condition and are thus specializations shared with the orang-utan. There are also many primitive characters shared with the orang-utan, such as the poor development of the supraorbital torus and the slope of the nose, and other characters like the great depth of the zygomatic bone that show greatest ressemblance to the orang-utan but are within the limits of variation of other hominoid species. Set against this list of characters are a few which show similarities with man. Of particular importance are the robustly built jaws, the lateral rotation of the canines and possibly low canine sexual dimorphism. Another similarity with man, the thick enamel and low cusp relief of the molars, is also shared with the orang-utan and cannot be considered diagnostic. The similarities with man are fewer in number and more strongly inter-related with each other than are the similarities with the orang-utan, and it is my belief that *Sivapithecus* must be seen as a relative of the orang-utan. It is shown thus on the accompanying cladogram.

It thus appears that *Sivapithecus* (including *'Ramapithecus'*) is part of the orang-utan clade, and both are more distantly related to man than are the African apes. In other words *'Ramapithecus'* can no longer be considered as part of the human lineage but as part of the orang-utan lineage. The recognition of this relationship provides fossil evidence for the divergence date of the orang-utan, and the time span of 8–12 Myr for the species of *Sivapithecus* is certainly compatible with the molecular date of 10 ± 3 Myr. □

Measuring atmospheric gases and aerosols

from D.D. Davis, W.L. Chameides and C.S. Kiang

SOME nine months ago several of the findings of the National Science Foundation-supported Global Atmospheric Measurements on Tropospheric Aerosols and Gases programmme (GAMETAG) were critically reviewed in these columns[1]. As part of the planning group for this field sampling programme, we welcome efforts to bring GAMETAG results before a larger spectrum of the scientific community. We would now like to go on to clarify some points that were made earlier and to add new information from the most recently available results.

The first point involves the NO/HNO_3 GAMETAG measurements. Before the GAMETAG flights, the little information available on NO_X in remote regions of the troposphere[2–6] suggested that NO levels were in the 100–1,000 p.p.t.v. (parts per 10^{12} by volume) range. The GAMETAG NO instrument, which had a lower detection limit of 50–60 p.p.t.v., gave readings which indicated that over thousands of miles of continental wilderness area and over large stretches of the open Pacific Ocean, NO levels were typically below that lower detection limit. The observations[7] are the first to indicate that NO_X levels in remote marine and northern continental troposheric air are much lower than previously believed. Subsequently, MacFarland *et al.*[8] reported that NO levels in a limited region of the equatorial Pacific were in the 1–10 p.p.t.v. range but the GAMETAG HNO_3 observations were the first extensive remote-global tropospheric data base for this species. Of particular importance is the observation that lower levels of HNO_3 are found in the marine boundary layer than in the middle free troposphere over extensive regions of the open Pacific Ocean. The results are in direct contradiction with all earlier predictions of NO_X/NO_Y altitude profiles and show the need for significant revisions in the tropospheric nitrogen budget.

D.D. Davis, W.L. Chameides and C.S. Kiang are in the School of Geophysical Sciences, Georgia Institute of Technology, Atlanta, Georgia 30332.

A second point involves new data now available on the question of photochemical activity over tropical and sub-tropical marine areas. Since Penkett wrote[1], the data have been released in manuscript form and are shortly to appear in print. Direct OH observations show tropical mid-day marine boundary layer OH levels ranging from $\sim 2 \times 10^6$ up to a high of 1.5×10^7 molecules per cm^3. It is argued by some that the absolute accuracy of the OH system may be in error by as much as a factor of two (the authors think this unlikely) but even if this were so and OH levels were assigned a value a factor of two lower, the conclusion that OH levels in the tropical marine boundary layer are typically quite high would still be clearly justified. It is estimated that the above observations imply a diurnally and seasonally averaged OH value of $\sim 2 \times 10^6$ molecules per cm^3 for the tropical marine boundary layer. For spring and summer conditions, at sub-tropical latitudes, a similar diurnally averaged OH value of 2×10^6 molecules per cm^3 is estimated from our measurements. Mid free-tropospheric (that is, 5–6 km) values over the above latitude range were typically a factor of two to three lower than those observed in the marine boundary layer. These OH values are significantly higher than the globally averaged value estimated by several investigators based on Northern/Southern Hemisphere CH_3CCl_3 measurements[9–11]. This result is consistent, however, with the higher than average levels of H_2O and UV actinic radiation that normally characterize the above latitude zones. They further suggest that in the tropical marine boundary layer, OH radicals are very likely to be responsible for initiating the oxidation of numerous compounds released into the atmosphere in reduced oxidation states. Approximate photochemical lifetimes based on oxidation by OH at a level of 2×10^6 molecules per cm^3 are SO_2 (3.5 days), CH_3SCH_3 (1 day), H_2S (1 day), NO_2 (0.7 day), C_2H_4 (0.7 day), C_3H_8 (0.2 day), CO (20 days) and CH_3Cl (124 days). Virtually all these lifetimes are much shorter than those predicted from washout/rainout or dry deposition.

A final point concerns tropical marine tropospheric-photochemical activity and its relation to the GAMETAG observations which showed no direct evidence of any photochemical generation of O_3. In spite of this observation, it is important to understand that the absence of O_3 generation cannot be equated with the absence of free radical chemistry or the lack of importance of photochemistry, in general. It instead suggests that of the possible HO_2 loss reactions (1)–(3):

$$HO_2 + HO_2 \rightarrow H_2O_2 + O_2 \qquad (1)$$

$$HO_2 + NO \rightarrow OH + NO_2 \qquad (2)$$

$$HO_2 + CH_3O_2 \rightarrow CH_3OOH + O_2 \qquad (3)$$

reaction (2), under tropical marine boundary layer conditions, is unsuccessful in competing with reactions (1) and (3). This result is a direct consequence of the previously described low levels of NO in the tropical marine boundary layer. It should be stressed, however, that the absence of O_3 production does not preclude the use of marine tropical areas of the world as future field sampling sites for studying free-radical tropospheric chemistry. In fact, the simplified chemistry of this region, resulting from highly reduced levels of hydrocarbons and their oxygenated analogues, should present the best opportunity for unravelling many key aspects of tropospheric chemistry. □

A hydrothermal plume remobilizes sedimentary organic matter

from Andrew S. Mackenzie

IN this issue of *Nature*, Simoneit and Lonsdale[1] describe petroleum found in dredge samples containing hydrothermal minerals, taken near a hydrothermal vent in the Guayamas Basin, Gulf of California. This 'hydrothermal petroleum' has a quite different composition from 'commercial petroleum' and its distinctive features are related to the rather special circumstances of its generation and migration. There is no evidence that the hydrothermal petroleum has a deep-seated origin and has emanated directly from the vent. Instead, the results suggest that part of the biologically derived organic matter of sediments in the neighbourhood of the vent can be remobilized and transported by the hydrothermal plume.

The most striking feature of the hydrothermal petroleum is its chemical resemblance to the organic matter which can be extracted, with common organic solvents, from relatively immature sedimentary rocks. Indeed, in one sample, a number of organic molecules, whose carbon skeletons have unambiguous links with known biological molecules, are still present as their less stable forms. Within this immaturity, the authors have detected certain components whose continued presence in large relative abundances is best explained by a relatively short-lived heating at temperatures well above those normally found in connection with petroleum formation. The evidence can best be accomodated in a model where the immature organic matter of the Quaternary sediments around the hydrothermal vent has come into contact with a hot hydrothermal plume and has then rapidly cooled as a result of migration in the hydrothermal flow and condensed at the seabed.

Organic geochemistry is much concerned with specific problems of petroleum geology, particularly those associated with thermal maturation[2]. The present paper[1] and others from the same laboratory[3] show some of the advantages of being able to study Earth processes at a specific organic molecular level and perhaps indicate the further contributions the field is poised to make in many other areas of the Earth sciences. Although a tremendous amount has been achieved in cataloguing a large number of specific but previously unknown chemical structures of the organic compounds occurring in sediments and petroleums[4], most of the applications to date have been very empirical. Simoneit and Lonsdale have made use of the sciences of chemical kinetics and thermodynamics in a descriptive sense to predict how the hydrothermal petroleum was formed. Large relative abundances of peri-condensed aromatic hydrocarbons and steroidal alkanes are said to reflect relatively short-lived contact with high temperatures (certainly greater than 250°C), because other reactions, which destroy the aromatic hydrocarbons[5], add hydrogen to triterpenoid alkenes[6] and isomerize triterpenoid and steroid alkanes[7-9], have been promoted to a lesser extent. This observation implies that the rates of the former types of reaction are accelerated to a greater extent by a major increase in temperature than those of the latter reaction types, and stems from the principles of chemical kinetics.

The chemical composition of the migrated hydrothermal petroleum also shows specific differences from organic matter found close to igneous sills[3]. Unsaturated hydrocarbons (alkenes) with carbon–carbon double bonds in the middle of the carbon chains occur in both environments, whilst those with double bonds at the end of the carbon chains are restricted to the organic matter next to sills. Simoneit and Lonsdale argue that the mid-chain alkenes can survive the migration in hot fluids, because of their higher thermodynamic stability, whereas the less stable terminal alkenes are completely destroyed.

Such descriptive integrations of physical chemistry into molecular organic geochemistry are welcome and valid. In the future, attempts will be made to derive more mathematical expressions for organic geochemical processes, particularly for those which can now be studied at a molecular level. Universally applicable expressions are more likely to emerge from the relatively simple interconversions between two known molecular structures than from the complex physicochemical processes which generate petroleum. These expressions will permit a more quantitative evaluation (what temperature and for how long) of the past geological events which have affected the organic mixtures being studied. In such a form molecular organic geochemistry will provide a new set of tools to Earth scientists. ☐

The Thar.

100 years ago From *Nature* 25, 26 January, 297, 1882.

THE THAR (*Capra jemlaica*). — The peculiar Himalayan Goat, known to the Indian sportsmen as the Têhr, Thar, or Tahir, was first described in 1828 by Hamilton Smith, and named *Capra jemlaica*, from the district of Jemlab, to the north of Nepaul, in which his specimen was procured. It is found, however, as Dr Jerden tells us, throughout "the whole extent of the Himalayas at great elevations, generally above the limits of forest and not far from the snow. It frequents rocky valleys and very steep and precipitous ground, and is often seen perched on what appear to be inaccessible crags. If alarmed whilst feeding, these animals all go off at full speed with a clattering sound, but soon halt and turn to gaze on the intruder."

Prostaglandins and cancer

from Peter Alexander

PROSTAGLANDINS, thromboxanes, prostacyclins and leukotrienes are produced by most tissues of the body by oxidation of arachidonic acid (AA). Their possible importance in cancer, at levels including carcinogenesis, the rate of proliferation of the tumours and the interaction between the tumour and the host, was the subject of a recent conference*.

Their significance can be seen in relation to the possibility that cancer may be prevented not only by withdrawing carcinogenic stimuli but also by intervening in the complex sequence of events between exposure to a carcinogen and the occurrence of a malignant neoplasm. Prostaglandin (PG) synthetase inhibitors, like aspirin, may be candidates for the 'chemoprevention' of cancer. Most chemical carcinogens need to be converted by metabolic processes into a reactive carcinogenic substance which can combine in a covalent chemical reaction with intracellular nucleophilic constituents. This metabolic activation can occur by reduction and by hydrolysis but most commonly requires oxidation. The cytochrome P450 monooxygenase systems have been shown to be an important oxidative pathway for the production of proximate carcinogens, and evidence is now accumulating that such oxidation can also occur during prostaglandin synthesis.

L. Marnett (Wayne State University, Detroit) showed that in the reactions involving benzopyrene, the conversion of the pro- to the proximate carcinogen was brought about by by-products (free radicals) produced during the synthesis of prostaglandins, although a direct role of lipoxygenase could not be totally excluded. With some tissue preparations, like ribosomes from ram seminal vesicles, an aspirin-like drug totally blocked the production of the proximate carcinogen, whereas with intact epithelial cells the active metabolite was produced via both the P450 and the prostaglandin pathway (T. Eling, National Institute of Environmental Research, North Carolina). Before inhibitors of AA metabolism can be seriously considered for chemoprevention, the relative contribution of prostaglandin-related oxidations in the formation of carcinogens must be determined in different organs. T. Zenzer (V.A. Medical Center, St Louis) presented early results from continuing *in vivo* studies with the potent bladder carcinogen FANFT (a 5-NO_2 furan derivative), the oxidative metabolite of which binds to DNA *in vivo*. Co-administration of aspirin prevents both binding to DNA and the appearance of early hyperplastic and possibly pre-cancerous lesions in the bladder. It will be another 12 months or so before it is known whether the incidence of bladder carcinomas in rodents has been reduced.

In many experimental systems carcinogenesis can be separated into two processes — initiation by the chemical reactive carcinogens and promotion. The most effective and widely studied promoting agents are phorbol esters such as TPA. The biochemical basis of promotion remains unclear because these agents induce a great many changes in cells and tissues. Prostaglandins and related substances could be involved as TPA increases release of their precursor, AA, from cell membranes and this produces an increase in cellular prostaglandins (E. Bresnick, University of Vermont). Indeed, this may contribute to the intense inflammation produced by all the phorbol esters that are active as promoters. R. Boutwell (University of Wisconsin) considers that elevation in ornithine decarboxylase activity is a key event in promotion and this is reduced if inhibitors of PG synthetase are given at the same time as TPA. The decisive test, however, is whether tumour promotion by TPA can be prevented *in vivo* by modulating prostaglandins. G. Fürstenberger finds that indomethacin, a potent prostaglandin synthesis inhibitor, prevents promotion by TPA of skin tumours following initiation with a polycyclic hydrocarbon and that administration of $PGF_{2\alpha}$ reverses this inhibition. But S. Fischer (Oak Ridge National Laboratory) is cautious about simplistic interpretations because she finds that low doses of indomethacin actually enhance promotion and that interference with promotion by high doses may not be due to inhibition of prostaglandin synthesis. She considers, however, that products from AA obtained by the lipoxygenase pathway may be concerned with promotion.

There is mounting evidence for a role of products of the AA cascade in the growth and spread of tumours once they have arisen. *In vitro* there are correlations between growth rate and intracellular prostaglandin concentrations which are not easy to interpret. Certain prostaglandins, notably PGE, slow cell division (B. Jaffe, State University of New York, Brooklyn, and S. Hammarstrom, Karolinska Institute), while L.J. de Asua (Friedrich Miescher Institut) demonstrated that $PGF_{2\alpha}$ is highly specific in causing cells rendered quiescent, for example by serum deprivation, to initiate DNA synthesis, probably by causing changes in the cytoskeleton. It is not, therefore, surprising that experiments in which inhibitors of prostaglandin synthesis are added to cell cultures or given *in vivo* to tumour-bearing animals give rise to conflicting results. In many respects the most impressive effects of prostaglandins on the growth of cells *in vitro* is the induction of maturation and their possible involvement in retinoid-induced differentiation. PGE, probably produced by monocytes, regulates proliferation and differentiation of stem cells in the bone marrow both *in vivo* and *in vitro* (R. Bockman, Memorial Sloan Kettering Cancer Center, New York). The observation that, *in vitro*, certain prostaglandins, notably PGA and PGI_2, can induce differentiation of myeloid (T. Breitman, NIH) and erythroid (G. Santarro, Ospedale Ruiniti, Rome) leukaemia cells as well as of mouse mammary carcinoma (P. Rudland, Ludwig Institute, UK) and neuroblastoma (K. Prasad, University of Colorado Medical Center) cells, constitutes the best reason for persevering with attempts to inhibit the growth of tumours using prostaglandins.

It is also possible that prostaglandins may influence the interplay between the host and the tumour. A popular concept is that some prostaglandins depress immune responses and that inhibition of prostaglandin synthesis will enhance a putative immune reaction of the host to the tumour. As yet, there is little hard *in vivo* data in support for immunotherapy based on prostaglandins. However, there are non-immunological interactions between the tumour and the host in which prostaglandins are involved and which might be manipulated in a therapeutically beneficial manner. Investigation into the control of metastases to bone and of the hypercalcaemia associated with malignancy using inhibitors of prostaglandin synthesis has been motivated by the finding that some prostaglandins cause osteolysis and calcium release from bone *in vitro* and that in two animal models, hypercalcaemia is induced by tumours that make large amounts of prostaglandin and can be stopped by aspirin-like drugs. Unfortunately, in man there is no consistent correlation between serum levels of prostaglandin and hypercalcaemia nor will inhibition of prostaglandin synthesis effect bone metastases or hypercalcaemia (T. Powles, Institute of Cancer Research, Sutton, UK).

Of considerable interest are experiments by K.V. Honn (Wayne State University, Detroit) which are based on the premise that platelet aggregation favours the spread of tumours. Accordingly, he tested

*An international conference on 'Prostaglandins and Cancer' was held from August 30 to September 2 1981, in Washington DC, under the chairmanship of T.J. Powles (Royal Marsden Hospital, Surrey), R. Beckmann (Memorial Sloan-Kettering Cancer Center, New York), K.V. Honn (Wayne State University, Detroit) and P. Ramwell (Georgetown University School of Medicine, Washington DC).

0028-0836/82/030188-02$01.00

in an animal tumour system selective inhibitors of Tx, which promotes platelet aggregation, and the administration of PGI_2 (or of substances which facilitate vascular PGI_2 synthesis), which prevents the formation of platelet emboli. Both procedures reduced the incidence of lung metastasis and in addition slowed the growth of the tumour growing at the site of injection. This latter effect is unlikely to involve interference with platelet aggregation and is thought to be a direct effect on the rate of proliferation of the tumour cells by increasing cyclic AMP.

The meeting was successful in bringing together cancer research workers and many of the leaders in the area of prostaglandins. It was encouraging to both groups that manipulation of the AA cascade may have a role in both prevention and treatment of cancer although the key experiments remain to be performed. □

A new British flower

from Peter D. Moore

BOTANISTS in the tropics will probably throw up their hands in horror but the fact remains that the discovery of a new species of flowering plant in the British Isles (and probably a native one at that) is news. Rix and Woods[1] have now officially recorded the finding of *Gagea bohemica* at Stanner Rocks, near Kington, mid Wales. Its inconspicuous leaves and flower undoubtedly contributed to its success in eluding detection until recently and to its initial misidentification. But the find also has some interesting biogeographical implications, for *G. bohemica* is a species of continental distribution, reaching its northwestern European limits in central Germany and the Seine Valley in France, and extending into central, eastern and southern parts of the European mainland. Stanner Rocks is a site far-removed from the remainder of its range.

One must consider the possibility that the plant has arrived at this location by chance dispersal but, as Carlquist[2] has recently emphasized, it is very difficult to study freak phenomena of this kind. *G. bohemica* reproduces by seed (though at Stanner Rocks only one per cent of the population flowers and no capsules have been observed) and by bulbils. Unlike some lake and seashore sites, a rock outcrop is an unlikely spot for the concentration of a bird migration route, making bird transport an unlikely explanation of its presence.

It is important to consider that Stanner Rocks boasts an unusual assemblage of rare plants currently exhibiting disjunct distributions, including *Lychnis viscaria, Veronica spicata* and *Scleranthus perennis.* Also, on some neighbouring outcrops in mid Wales, is *Potentilla rupestris*[3]. All of these have continental distributions, though *L. viscaria* and *S. perennis* extend further north than the others.

All these species are plants of low growth habit and demand light. Pigott and Walters[4] proposed that plant assemblages having a number of open habitat species of generally disjunct distribution were often associated with disturbed or unstable sites in which the forest cover had remained incomplete throughout post-glacial time. The plants now isolated in such sites may represent relicts of the vegetation of late-glacial or early post-glacial times, which have been extinguished over the bulk of their former range by forest expansion and consequent shading. In the case of Stanner Rocks, such an explanation is supported by the sub-fossil record of certain of the plants concerned. *S. perennis* pollen has been found in late-glacial sediments of mid Wales[5] and a seed of *L. viscaria* was found by Dickson, Dickson and Mitchell[6] in late-Devensian material from the Isle of Man. Unfortunately, no sub-fossil records are available for *V. spicata, P. rupestris* or *G. bohemica* in Britain, but their current, rather southerly, continental distributions do not make them likely candidates for late-glacial relicts.

Gagea bohemica

Peter D. Moore is Senior Lecturer in the Department of Plant Sciences, University of London King's College, 68 Half Moon Lane, London SE24 9JF.

Lamb[7] has constructed global maps of probable atmospheric pressure systems during winter and summer at several stages of post-glacial history, and he concludes that the early part of the post-glacial in north-west Europe (pre 7,000 BP) was characterized by a vigorous circulation of air masses which would have brought dry, anticyclonic conditions to the area both in winter and summer. It may well be that many southern continental plant species were able to migrate into what are now oceanic regions in the north and west during those times. This would have brought into contact a variety of continental species of somewhat southerly and northerly affinities; it is interesting to note that all five of the species under discussion here are currently found together in central Poland, which may give some indication of the climatic conditions during the period of mixing. Rix and Woods[1] note that the Stanner Rocks specimens of *G. bohemica* are morphologically most akin to the western French populations on the continent, which may suggest a west European origin for the British population of this species.

The subsequent history of the mid Wales area has involved forest spread and increasing oceanicity of climate, both of which will have operated against the survival of all these species; but the rock outcrops, such as Stanner, have evidently acted as refuges. Such outcrops would not only have provided steep, unstable slopes keeping the woodland and canopy open and discontinuous, but may also have created microclimatic conditions appropriate for the survival of continental species of plant. *G. bohemica* on Stanner Rocks is currently restricted to shallow soils on southern and eastern aspects. These locations would be well insolated in summer, providing a 'micro-continental' climate, rather analogous to some of the present-day East Anglian breckland habitats of *S. perennis* and *V. spicata.* The importance of aspect for survival of a species at the edge of its climatic range is well documented for such plants as *Cirsium acaule*[8] which reaches its northern British limit in Derbyshire but survives there mainly on southerly aspects. Even under these conditions fruiting is poor and experiments involving daily spraying of the developing fruit with water, thus lowering overall temperatures, reduced success even further. *G. bohemica* fails to fruit at Stanner, but persists by vegetative propagation.

The record of *G. bohemica* from Stanner Rocks is thus more than just one more species on our list — it may also provide important evidence of the climatic and vegetational history of the British Isles. □

Analysing atmospheric carbon dioxide levels

from Michael J. Rycroft

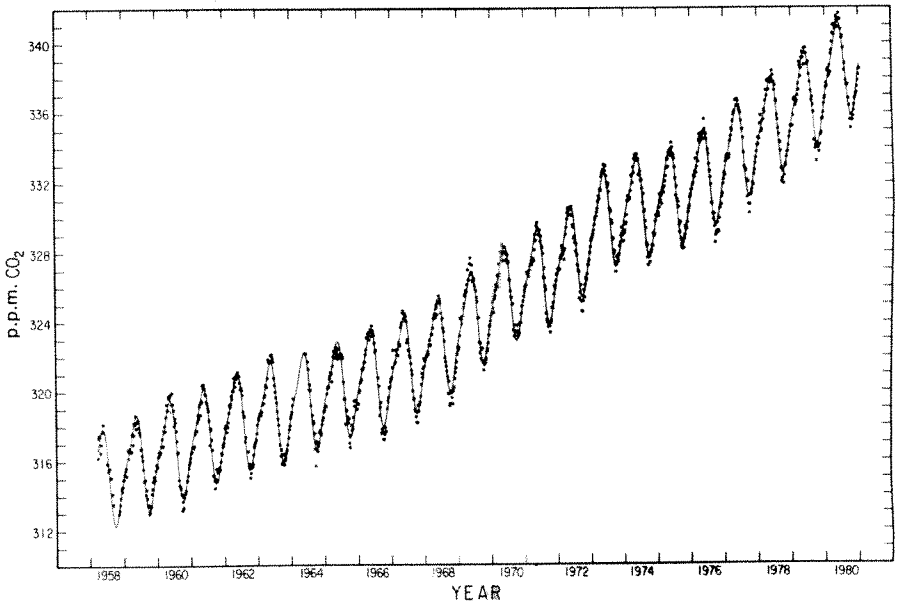

Fig. 1 Atmospheric CO_2 concentrations (weekly averages) measured at Mauna Loa, Hawaii (courtesy of C. D. Keeling). The curve is a spline fit assuming an annual variation of constant amplitude superposed on a long-term trend.

THE possibility that changes in climate may be brought about by increasing levels of carbon dioxide in the atmosphere made a recent conference* devoted to the analysis and interpretation of atmospheric CO_2 data of particular significance. The CO_2 increase is caused primarily by the burning of fossil fuels and secondarily by deforestation in the tropics and changing agricultural practices. Very recently such problems have been put in context by Bach *et al.*[1] and Kellogg and Schware[2], and discussed by Kandel[3]. Following the pioneering work of Manabe and Wetherald[4], several complicated model calculations[5-10] have been performed; these have been reviewed by Schiff[11].

For a doubling of the CO_2 content of the atmosphere, these models calculate that the global mean surface air temperature would rise by 2–4 deg, but with a larger increase at high latitudes[12]. It has been suggested that this could lead, within a thousand years, to deglaciation of the West Antarctic ice sheet[13,14]. The consequent rise of the mean sea level[15,16] would have a profound effect as population is concentrated in low-lying areas of the world. Associated with the temperature rise would be changes of atmospheric circulation and the spatial distribution of rainfall. The changed soil moisture patterns could have serious implications for agriculture and food production. The study of atmospheric CO_2 is thus closely linked with other biospheric processes, studies of carbon budgets and the global carbon cycle[17], the biogeochemical cycles of nitrogen, phosphorus and sulphur, and their mutual interactions[18] in the atmosphere and oceans[19].

R. M. Rotty (Institute for Energy Analysis, Oak Ridge Associated Universities, US) has shown earlier that the global production of anthropogenic CO_2 by fossil fuel burning (98%) and cement manufacture (2%) has increased exponentially between 1860 and 1914 and since 1945. Simple exponential growth, with an *e*-folding time of 24 years, corresponds to compound interest at 4.3% per year from a pre-Industrial Revolution value of at most 290 parts per million (p.p.m.) by volume. However, the situation is not so simple. From 1950 to 1973, the growth rate of CO_2 emission into the atmosphere was 4.6%, and since 1973, when OPEC increased oil prices dramatically, the growth rate halved to 2.3%. At present, 5.3 Gigatonnes (5.3×10^{12} kg) of carbon are being released per year into the atmosphere as CO_2 (19.4 Gt per year). As this adds to the 700 Gt of carbon already present in the atmosphere as CO_2, it would seem that the CO_2 content of the atmosphere should, at the present time, simply increase by 0.76% per year. With a typical atmospheric CO_2 concentration of 335 p.p.m., it might be expected that the concentration of atmospheric CO_2 should increase by 2.5 p.p.m. per year.

However, C. D. Keeling (Scripps Institution of Oceanography) presented measurements of atmospheric CO_2 concentrations made since 1958 using a non-dispersive IR absorption spectrometer at Mauna Loa Observatory, Hawaii, at 20°N. Each point in Fig. 1 is a weekly average; the annual variation is explained by seasonal changes of the rates of photosynthesis and respiration by plants and the soil. Last year, the 340 p.p.m. value was exceeded for the first time. Also evident in the figure is the long-term, quasi-exponential increase of CO_2 concentration, at a rate of 1.3 p.p.m. per year, or 0.40% per year. Thus only 53% of the increased CO_2 is retained in the atmosphere; this is termed the airborne fraction. The remaining 47%, or excess fraction, is taken up mainly by the oceans at middle and high latitudes. Quantitative studies of the air–sea interaction are difficult; comparisons between modelled and observed results are complicated by the fact that the time scales of oceanic CO_2 uptake are between 10 and 100 years (at lesser to greater depths), and are of the same order as the 24 year time constant of the atmospheric CO_2 increase.

Of the CO_2 production, R. M. Rotty showed that 91% occurs at latitudes between 30 and 60°N, primarily over land. This fact accounts, in part, for the CO_2 latitudinal gradient, shown as differences from the Mauna Loa mean in Fig. 2, and derived from measurements made at different observatories and aboard ships and aircraft. Additional factors are the CO_2 source associated with the warm sea surface in equatorial regions and the relatively slow interhemispheric mixing of atmospheric CO_2 across the Inter-Tropical Convergence Zone. CO_2 concentration differences of 1 p.p.m. can be accounted for by the interhemispheric CO_2 fluxes of

about 1 Gt per year

The largest annual variations of CO_2 concentration, with a difference of 15 p p m between maximum and minimum values, occur between 50 and 70°N, there being a 6 p p m difference at Mauna Loa and no annual variation between 10 and 20°S There is also some evidence of two and four year periodicities R B Bacastow and C D Keeling (Scripps Institution of Oceanography) have associated large increases in the CO_2 concentration with a minimum value of the Index of the Southern Oscillation of the atmosphere and with El Nino occurrences These latter events — the presence of 2 deg warmer, nutrient-poor water in a region off the Peruvian coast at 80°W and out to 180°W, which is associated with a reduction, or even cessation, of the upwelling of colder, nutrient-rich water — are of great significance to the region's fishermen

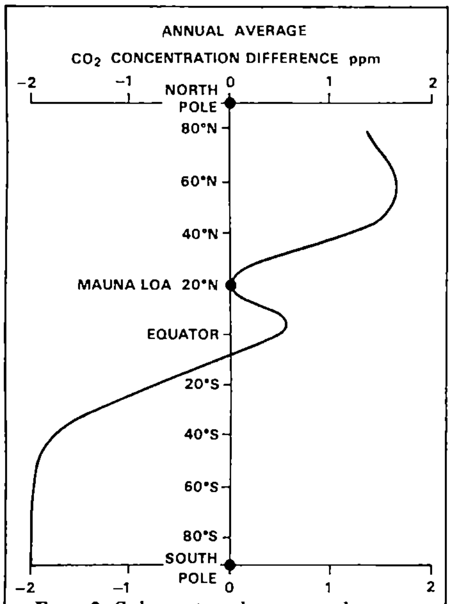

Fig 2 Schematic diagram showing latitudinal differences of annual mean atmospheric CO_2 concentrations from the annual mean value at Mauna Loa, based on observations reported at the 1981 Bern conference by P Hyson and G I Pearman (CSIRO, Australia), C D Keeling (Scripps Institution of Oceanography) and W D Komhyr (NOAA, Boulder, Colorado)

Evidence for slight decreases in the atmospheric $^{13}C/^{12}C$ ratio has been obtained from mass spectrometer analyses[20] Both $^{13}C/^{12}C$ and $^{14}C/^{12}C$ ratios in the cellulose of tree rings similarly reflect the ratios' atmospheric values during successive year's growing seasons It is concluded that biospheric processes, both soil and plant, acted as a net source of atmospheric CO_2 from 1860 until about 1950, since then, biospheric sources and sinks of CO_2 have cancelled each other out For example, the present deforestation in the tropics could be balanced by reforestation at middle latitudes Also, ^{14}C in corals gives information on CO_2 uptake by the surface water of the oceans and on surface water circulation Of course, the radiocarbon concentrations of the atmosphere and ocean have risen considerably since the thermonuclear bomb tests of the 1950s

To identify new trends, continuing and uninterrupted measurements of atmospheric CO_2 concentrations are required at up to 20 well distributed sites around the globe The required absolute accuracy is ±0 1 p p m , this is achievable only by performing very careful intercalibrations, using standard gases, between the different experimental groups Further, there is a pressing need for additional observational studies of seasonal and annual variations of atmospheric CO_2 at particularly interesting sites Such observations, required to a relative accuracy of ±0 1 p p m , can be interpreted in terms of sources and sinks of CO_2, and should lead to an improved understanding of the carbon budget With improved observational knowledge, and with the further development and validation of climate models, better predictions may then be made of the environment in which mankind will find itself in the coming decades and centuries □

Mammary gland as an endocrine organ: implications for mastectomy

from Jared M Diamond

THE traditional view of the mammary gland is that it receives many hormonal signals but sends none Oxytocin acts on it to trigger milk ejection, prolactin to stimulate milk secretion, and oestrogens, progesterone, prolactin and growth hormone to stimulate gland growth during pregnancy The only direct signals that the mammary gland sends to the rest of the body have been thought to be concerned with its own regulation — nerve impulses (the suckling reflex) cause prolactin and oxytocin release from the pituitary and reflexly control milk production This traditional view has determined the assessment of the costs and benefits of mastectomy, an operation that has often been used to deal with mammary tumours Although mastectomy has been increasingly criticized for its psychological consequences, it has at least been thought that the operation is without physiological consequences since the mammary gland has no role outside of lactation

This dogma has been undermined by important recent studies[1-4] of Peaker (Hannah Research Institute, Ayr) and Maule Walker (ARC Institute of Animal Physiology, Babraham), demonstrating that, in goats, the mammary gland releases hormones into the general circulation and mastectomy causes major disturbances of other reproductive functions besides lactation These observations clearly indicate the need for the study of possible physiological consequences of mastectomy in humans

The roots of the new observations go back at least 75 years In 1906 Marshall and Kirkness[5], studying urinary sugars in mastectomized guinea pigs, briefly commented "Considerable difficulty was experienced in inducing the guinea pigs to breed after the removal of the [mammary] glands, some of them failing to do so although kept for over eight months in company with males, and in an apparently perfectly healthy condition" Four of these mastectomized guinea pigs did eventually become pregnant, resulting in one premature still-birth, one abortion and four normal births In the late 1950s Linzell worked out procedures for autotransplanting mammary glands of goats, and in the following 20 years he used the improved experimental access provided by this preparation to answer many problems of mammary physiology Early in these studies he noted[6], in the course of a long paper on milk secretion, that loss of mammary tissue in goats was associated with increased incidence of several reproductive disorders infertility, mastitis, abortion and maternal death at parturition Peaker and Maule Walker have now followed up these observations by studying mastectomized goats, four of which have been followed through three pregnancies The reproductive consequences of mastectomy in the first breeding season were a lengthened first oestrus (115 h vs 30 h in controls), shortened oestrous cycles (8–17 days vs 22–24 days in controls), reduced fertility and slightly shortened pregnancy In the second pregnancy, and even more in the third pregnancy, there was peripheral oedema before term, premature onset of labour and prolonged labour with weak cervical contractions and no cervical dilation

How does removal of the mammary gland lead to these reproductive disturbances? Several possible mechanisms involve disruption of lactation, which is known to have systemic effects Nerve impulses from the mammary gland to brain during lactation stimulate reflex release of pituitary hormones that control not only milk production in mammals generally but also embryonic development in

0028-0836/82/030191-02$01 00

marsupials[7] Lactational amenorrhoea may similarly involve mammary reflex control of pituitary hormones, in this case inhibition of follicle-stimulating hormone and luteinizing hormone release Withdrawal of large quantities of glucose and other substrates for milk synthesis from the bloodstream leads to changes in levels of hormones that regulate blood concentration of these solutes, such as insulin and glucagon

However, Peaker and Maule Walker observed no difference between lactating and non-lactating non-mastectomized goats in fertility or in oestrous cycle periodicity Furthermore, the mastectomized goats exhibited oestrous disorders and impaired fertility before they had ever become pregnant or lactated These facts suggest that interruption of lactation is not responsible for the reproductive disorders associated with mastectomy A more likely explanation comes from new evidence that non-lactating mammary gland releases hormones into the systemic circulation, in addition to producing local hormones such as prostaglandins during lactation From earlier observations by Linzell and colleagues[8-10] that the mammary gland of goat can metabolize steroid hormones, Maule Walker and Peaker[1] have gone on to find that the rise in plasma concentration of oestradiol-17β during the last four days before term is due almost entirely to increased production of the hormone by mammary gland

It remains to be seen whether reproductive disorders in mastectomized goats are related to this mammary production of oestradiol-17β, or of other known steroid, peptide, or protein hormones, or of 'new hormones', or else to a non-hormonal mammary signal The great variability among mammals in the control of reproduction suggests that the goat is not necessarily a universal model and studies on other mammalian species, especially on humans, are now urgently needed ☐

Exciting Rydberg atoms in cavities

from Peter Knight

HIGHLY excited atoms with one electron orbiting at large distances from an unexcited core are termed Rydberg atoms and have remarkable properties Their size gives them a large polarizability, and they are easy to ionize in weak electric fields If they possess a large angular momentum they do not return rapidly to their ground state by radiative decay simply because decay photons cannot easily carry away all that excess angular momentum Rydberg atoms provide a unique vehicle for studying radiative processes over long times In mid 1981, Kleppner (*Phys Rev Lett* **47,** 233, 1981) proposed using such atoms to study the effects of cavity mode confinement in partially 'freezing out' spontaneous decay rates (*Nature* **293,** 514, 1981) A recent experiment by Vaidyanathan, Spencer and Kleppner (*Phys Rev Lett* **47,** 1592, 1981) reports the observation of such waveguide effects, not on spontaneous transitions but on transitions induced in the Rydberg atoms by thermal blackbody radiation

Rydberg atoms have been used before as detectors of far-IR and microwave blackbody radiation (*Nature* **279,** 476, 1979) but only in effectively unbounded space Kleppner's new experiment reports a sudden increase in the induced lifetime of a Rydberg atomic transition between two conducting plates when the resonant wavelength is increased beyond the waveguide cut-off (twice the plate separation *d*) The conducting plates are unable to support field modes of wavelength less than 2*d* in the direction normal to the plates In addition, those modes parallel to the plates have their density altered but not turned off Thermal radiation can only be supported on these modes so that transitions induced by blackbody radiation inside the plates are sensitive to the confining geometry

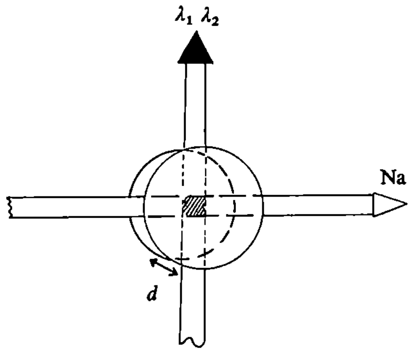

Fig 1 Schematic outline of experiment in which a sodium atomic beam is excited by lasers of wavelength λ_1, λ_2 to the 29d state between two conducting plates

The technique used to observe these waveguide effects by Kleppner and his group is particularly ingenious and is outlined schematically in Fig 1 The sodium 29d Rydberg state is populated by stepwise absorption from two pulsed lasers of wavelengths λ_1 and λ_2 which drive the transitions 3s to 3p to 29d in an atomic beam travelling between two conducting plates separated by 1/3 cm The whole apparatus is placed in a shielded box at 180K so that the photon occupation number at wavelength $\lambda \sim 2d$ is approximately 86 All polarizations in the transition are possible The transition 29d to 30p at a wavelength of 2/3 cm ($\sim 2d$) is chosen for study and is excited by the thermal field at a rate of 300 per second Transitions to other levels at $\lambda \neq 2d$ are of course also induced and contribute to a *d*-insensitive background

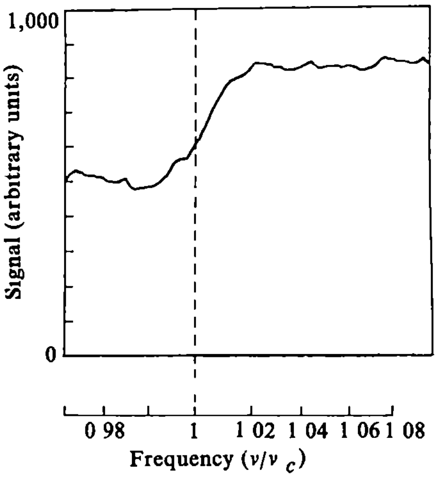

Fig.2 Blackbody radiative transfer signals 29d–30p in sodium between parallel conducting plates as the transition frequency ν is Stark tuned through the cut-off frequency $\nu_c = c/2d$ (from Vaidyanathan *et al*)

The plate separation is kept fixed but the transition wavelength is varied by exploiting the large polarizability of Rydberg states to Stark-shift energy levels in a small d c voltage across the plates The cut-off frequency $\nu_c = c/2d$ is 1 48 cm^{-1} As the electric field across the plates is varied from 0 7 to 5 7 V cm^{-1}, the transition frequency varies from 0 97 ν_c to 1 11 ν_c The transition rate for the production of 30p atoms is measured by selectively ionizing only those 30p atoms making the transition, and counting the ions As the transition frequency ν approaches the waveguide cutoff frequency ν_c, the rate of transition suddenly changes (Fig 2) on the right-hand side, blackbody photons can fit between the plates, and on the left-hand side they cannot, decreasing the 30p production rate As ν increases beyond ν_c, the modes normal to the plate surface are switched on The Einstein relationships between stimulated and spontaneous transition rates imply that spontaneous decay was similarly affected in this experiment The experiment of Vaidyanathan *et al* is a beautiful example of how Rydberg atoms are sensitive to their immediate environment, making them the perfect testbed for what would otherwise be minute and unmeasurable effects ☐

Long-term (9–32 month) current meter records from the eastern North Atlantic (41° N–59° N) suggest that, remote from the influence of the Western Boundary Current, eddy kinetic energy (K_E) at all depths is principally a function of wind stress and stratification, generated during the winter and early spring, propagating to abyssal depths and decaying to a minimum in late summer. Although this seasonal variation in K_E has not previously been described from the midlatitude ocean, some theoretical basis for it is presented

IN their analysis of long-term (644 days) current meter records from the northern Rockall Trough (IOS Mooring I4, 58°50′ N 11°40′ W, Fig 1), Gould and Cutler[1] report a well-defined seasonal signal in eddy kinetic energy estimated at depths of 200, 1,000 and 1,500 m in 1,800 m water depth Each record was first low-pass filtered using a gaussian filter similar to that described by Schmitz[2] with a high frequency cutoff around 0 5 cycles per day (c p d) Finding clear evidence of energetic winter fluctuations in the filtered time series, see for example, Fig 2*a*, each record was then divided into 60-day pieces each overlapping by half their length, and for each piece the eddy kinetic energy (K_E) over a selected band of periods (2 92–40 days) was estimated using spectral analysis techniques similar to those defined by Schmitz and Hogg[3] From this the seasonal nature of the fluctuations is obvious (Fig 2*b*)

We extend this analysis to a widely-scattered range of sites in the eastern North Atlantic and to water depths >4,700 m using long-term (9–32 month) records obtained by the Ministry of

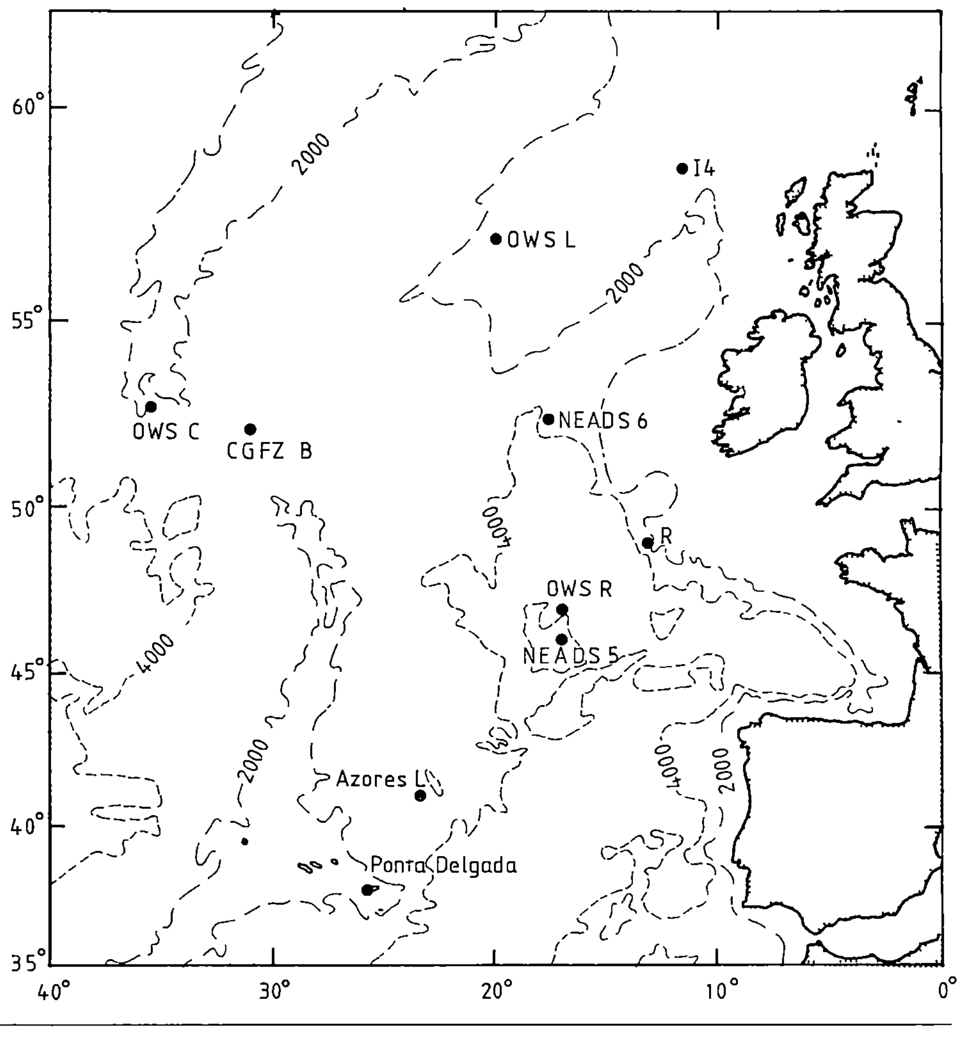

Fig. 1 Location of six current-meter moorings and three Ocean Weather Stations The 2,000-m and 4,000-m isobaths are also shown

Agriculture, Fisheries and Food (MAFF), Fisheries Laboratory, Lowestoft and the Institute of Oceanographic Sciences (IOS), Wormley The 60-day piece-length and low-pass filtering techniques are standard throughout, however, the period bands used vary, to accommodate records of different spectral characteristics and because of differences in the spectral analysis procedures at the two laboratories By the Blackman–Tukey method[4] (MAFF) spectral estimates are derived for frequencies which are fractions of the number of lags ($L = 20$ throughout) while the FFT method[5] (IOS) obtains estimates at frequencies corresponding to fractions of the length of record ($t = 60$ days) Thus generally,

$$K_E(\nu_1\nu_2) = \Delta \sum_{\nu_1}^{\nu_2} K_E(\nu)$$

where $K_E(\nu_1\nu_2)$ is the fluctuation (eddy) kinetic energy between frequencies ν_1 and ν_2, and Δ is the bandwidth of the spectrum ($1/2L$ or $1/t$ according to method) In practice, K_E estimates are reported below for two bands of periods, K_E(3–27) covering periods from 3 to 26 7 days and K_E(3–80) covering those from 3 to 80 days Where the earlier results of Gould and Cutler are described, K_E(3–40) denotes periods from 2 92 to 40 days K_E(Rec) denotes the total kinetic energy per unit mass associated with the entire range of 'eddy' frequencies accessible in the full low-passed record ($\nu = 1/2t$ to 1/2 c p d], that is $K_E(\text{Rec}) = 1/2[\text{var } u + \text{var } v]$, where var u and var v are the variances of the east and north velocity components respectively

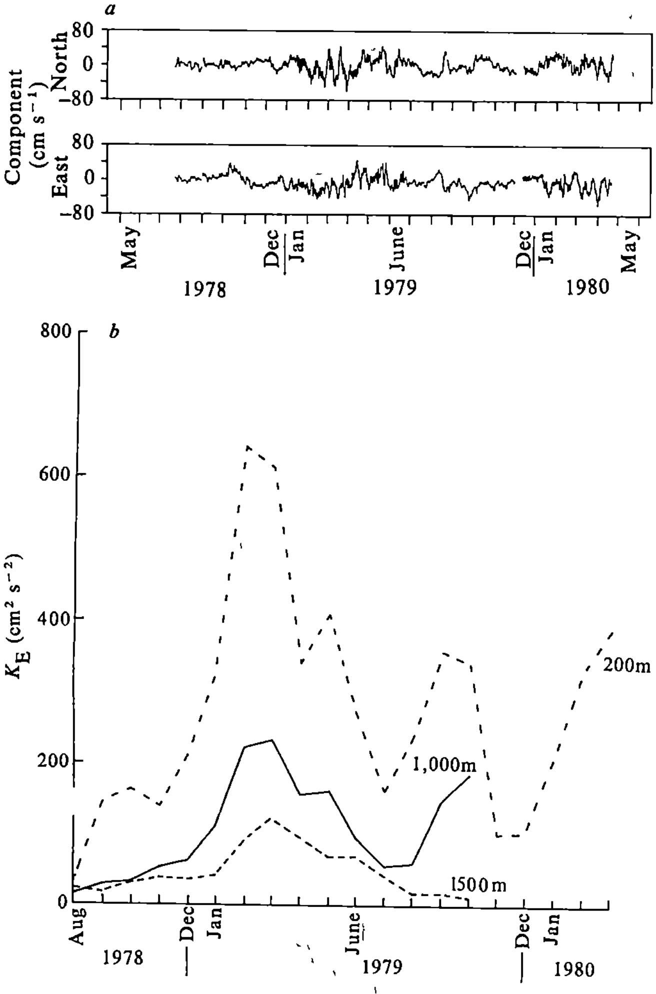

Fig. 2 *a*, Low-pass filtered time-series of north and east current components at Mooring I4 (Rockall Trough, 58°50′ N 11°40′ W), 200 m depth, July 1978–April 1980 *b*, Estimates of eddy kinetic energy in the period band 3–40 days [K_E(3–40)] at 200-, 1,000- and 1,500-m depth, Mooring I4 (Rockall Trough) Individual estimates are for 60-day pieces of record, each overlapping by half their length

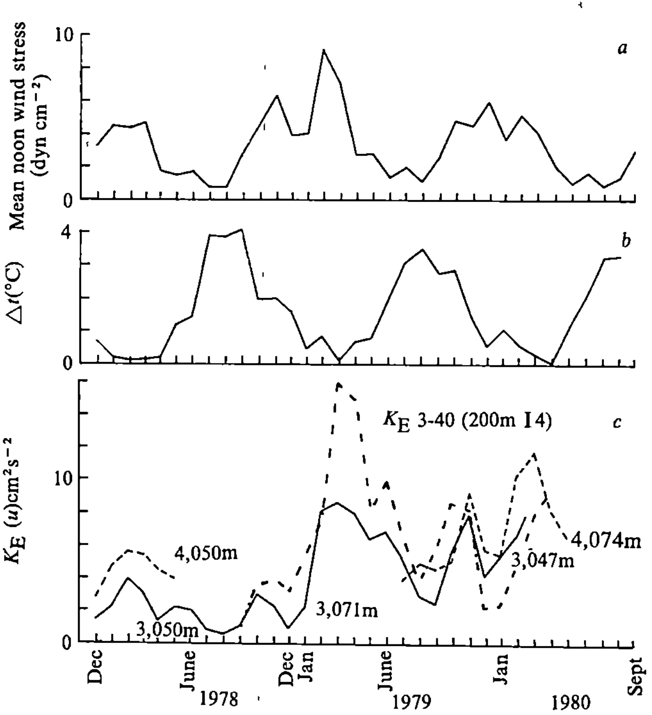

Fig. 3 *a*, Mean noon wind stress at OWS LIMA [57° N 20° W], December 1978–September 1980 *b*, 0–450 m temperature difference at OWS LIMA, from XBT observations *c*, Time-variation of eddy kinetic energy [K_E(3–27)] in the east-west current component at 3,050-m (——) and 4,050 m-depth (– – –), NEADS-6 mooring [52°30′ N 17°45′ W] The 200-m curve of K_E(3–40) from Mooring I4 (Rockall Trough) has been superimposed with a 1-month lag (- - -) to show the close correlation and the apparent 1-month delay in the deep water

Seasonal signal in eddy kinetic energy

The records from the Rockall Trough (Fig 2*b*) appeared to show three characteristics, apart from the obvious seasonality of K_E(3–40) First, the amplitude of the seasonal peak is markedly depth dependent, varying from ~640 cm^2 s^{-2} at 200 m to ~120 cm^2 s^{-2} at 1,500 m Second, the curves seem to lag in time with increasing depth, from 200 m to 1,500 m for example the primary winter peak is delayed by ~1 month Third, there are signs that the main winter peak centred on February–March is preceded by a secondary peak of smaller amplitude in September–October at the time of the equinoctial gales (but before the complete eradication of the seasonal thermocline)

Figure 3 extends this analysis to greater depths using the multiyear records from the NEADS-6 site [52°30′ N 17°45′ W, North-east Atlantic Dynamics Study] on the continental rise at the mouth of the Rockall Trough (see Fig 1) This mooring has been operated continuously by MAFF since October 1977 From 60 day overlapping pieces of the low-passed records, Fig 3*c* illustrates the time-variation of eddy kinetic energy [(K_E(3–27)] in the east–west (along isobath) current component for the 830 day record at 3,050 m and for the discontinuous 602 day record at 4,050 m Water depth is ~4,100 m On the same time-base, Fig 3 *a* describes the mean noon wind stress for each month at OWS LIMA [57° N 20° W] calculated using a quadratic wind stress law with variable drag coefficient as defined by Heaps[6], and Fig 3*b* shows the 0–450 m temperature difference at LIMA from XBT observations

Figure 3 confirms many of the features found in the Rockall Trough, though in this case at abyssal depths roughly coincident with the winter windstress peak and with the eradication of the seasonal thermocline, there is evidence for a February–March peak in the *u* contribution to K_E(3–27) in each of the 3 years, preceded by a lesser peak in October–November (at the time of the equinoctial gales but when some residual stratification remains in the upper water column)

Figure 3 also gives some indication as to the scale of the forcing and on the phase lag with depth In Fig 3*c* the 200 m curve of $K_E(3\text{–}40)$ at I4 (Rockall Trough) has been superimposed on the NEADS-6 time series with a 1-month lag to show both the close correlation and the apparent 1 month delay in the deep water Despite a horizontal separation of >800 km between I4 and NEADS-6, the correlation is sufficiently close between the 200 m (I4) and 3,050 m (NEADS-6) records at 1-month lag to suggest a common broad-scale forcing (over the 19-month overlap period $r = 0\ 76$ though with independent estimates only every 2 months) Note that although the I4 mooring had its main buoyancy close to the surface (150 m), the tidal constituents of the records are constant from season to season, suggesting that the records are free from wave-induced contamination[7] In the case of the NEADS-6 mooring there is no possibility that the observed variation in 'eddy' energy could be due to wave action or to mooring motion arising from it as the uppermost part of the mooring lay at 3,000 m depth throughout the 32-month period of record (The same is true for all other MAFF moorings described below, whose main subsurface buoyancy varied from 1,000 to 4,000 m depth) Depth-modified Aanderaa RCM-4 instruments were used throughout

The 3,050 m time-series in Fig 3*c* was used to investigate the spectral composition of the additional 'winter' eddy kinetic energy The 343 day series from the second deployment at this depth was halved to provide two records of 172 day representing the quiescent 'summer' half year (1 July 1978–19 December 1978) and the energetic 'winter' half year (19 December 1978–8 June 1979) Figure 4*a* shows the winter minus summer spectral energy density for both the u and v spectra At the lowest and highest frequencies of the spectrum there is little difference in energy between summer and winter, but each component shows a sharp winter excess of energy at (different) intermediate frequencies The winter excess in the u (along isobath) component is of greater amplitude and peaks at a longer period (25 days) than the v component (12 5 days) in this particular pair of half-years It is also the more conservative in time Of the three possible (overlapping) adjacent pairs of winter–summer periods in the 3,050 m record, and in the single (discontinuous) winter–summer pairing of the 4,050 m record, the winter excess of eddy energy peaked at 33, 25, 25 and 25 days respectively in the u component while the corresponding peaks in the v component were much more variable and ill-defined (except for the pairing shown in Fig 4*a*)

Figure 5 examines records from four additional sites between January 1977 and May 1980 to test whether the seasonal signal in eddy energy is restricted merely to the Rockall area or is a more widespread and general characteristic of the eastern North Atlantic In most cases, estimates of $K_E(3\text{–}27)$ and $K_E(3\text{–}80)$ are superimposed Locations of the moorings and of the three Ocean Weather Stations discussed are shown in Fig 1

Figure 5 *a–e* displays results from the NEADS-5 site at ~46° N 17° W, in the foothills of the Mid Atlantic Ridge close to its junction with the Porcupine Abyssal Plain Figure 5*a*, *b* shows IOS records (452 and 425 days respectively) from 600 and 3,000 m depth, while Fig 5*c–e* (the deepest records discussed here) is from a later 1-yr reoccupation of the site by MAFF Of Fig 5*f–i* (all MAFF) Fig 5*f*, *g* shows 253 day records at 2,977 and 3,977 m depth from the lower north wall of the Charlie Gibbs Fracture Zone, Southern Trench, at 52°09′ N 31°00′ W[8], Fig 5*h* is a 340 day record from 4,046 m depth on the hilly eastern flanks of the Mid Atlantic Ridge, north-east of the Azores [41°00′ N 23°18′ W] and Fig 5*i* is a 1-yr record at 2,049 m depth from the European Continental Slope (48°59′ N 12°53′ W)

Coupling these results with the earlier discussion of I4 and NEADS-6 we find

(1) At all six sites, ranging in latitude from 41° N to 59° N, ranging in sampling depth from 200 to 4,710 m and with records ranging in total eddy kinetic energy [K_E(Rec)] from the highest values yet encountered in the eastern basin [$K_E(\text{Rec}) = 196\ \text{cm}^2\,\text{s}^{-2}$ at 200 m, I4] to very nearly the lowest [K_E(Rec) =

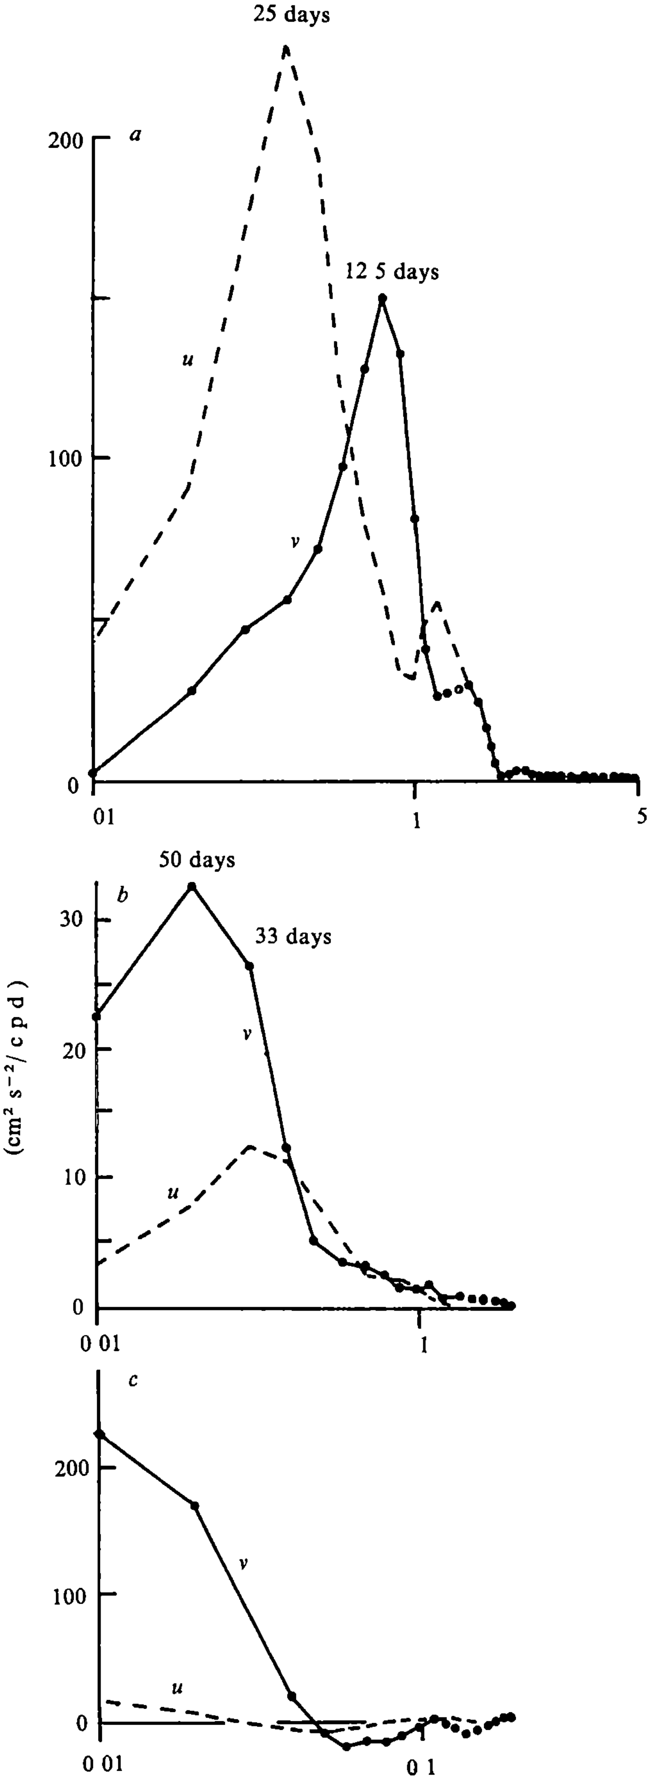

Fig. 4 Winter minus summer spectral energy density for both the zonal (u) and meridional (v) current components at *a*, 3,050-m depth NEADS-6 (52°30′ N 17°45′ W), *b*, 4,050 m depth, NEADS-5 (46° N 17° W), *c*, 2,049-m depth, mooring R (48°59′ N, 12°53′ W, European continental slope)

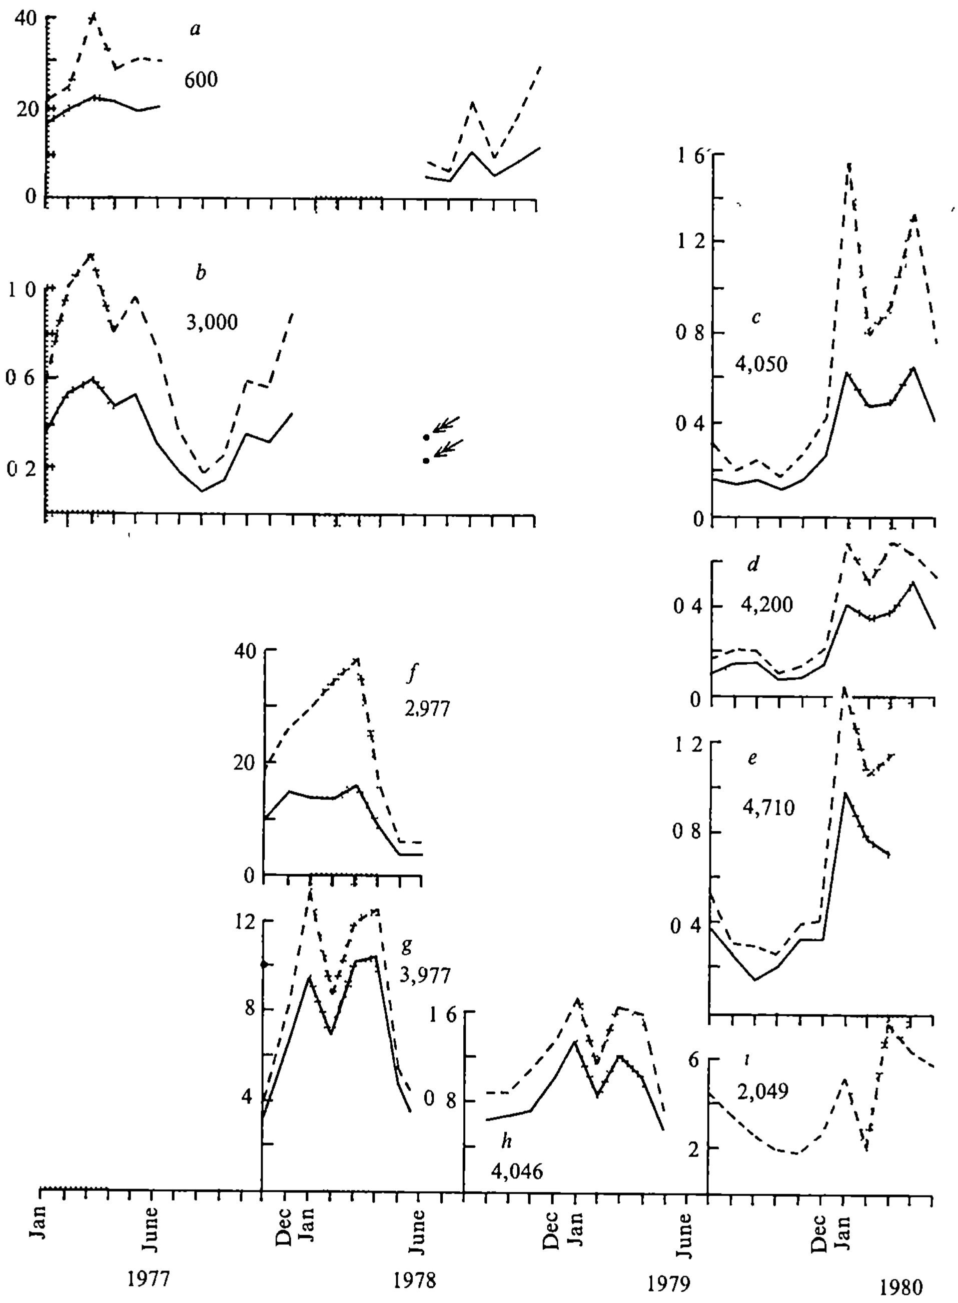

Fig. 5 Time series of eddy kinetic energy estimates in the period bands 3–27 days (——) and 3–80 days (– – –) at *a*, 600-m depth, NEADS-5 [46° N 17° W], *b*, 3,000-m depth, NEADS-5, *c*, 4,050-m depth, NEADS-5, *d*, 4,200-m depth, NEADS-5, *e*, 4,710-m depth, NEADS-5, *f*, 2,977-m depth, mooring B, Charlie–Gibbs Fracture Zone, southern trench [52°09′ N 31°00′ W], *g*, 3,977-m depth, mooring B, Charlie–Gibbs Fracture Zone, southern trench, *h*, 4,046-m depth, mooring L, Azores Array [41°00′ N 23°18′ W], *i*, 2,049-m depth, mooring R, European continental slope [48°59′ N 12°53′ W]

0 6 at 4,200 m, NEADS-5 (ref 9)], there is a clearly-defined seasonal variation in K_E(3–27) or K_E(3–80)

(2) All these sites are characterized by some degree of bottom slope, with either gently-sloping, hilly or abrupt topography Conversely (though not shown here), no clear seasonal variation in K_E could be detected at sites on the flat abyssal plains, for example, at MAFF sites N, O or P on the Porcupine Abyssal Plain[9] (within the NEADS-6–NEADS-5–R triangle) or at the NEADS-3 site on the Iberian Abyssal Plain (42° N 14° W)

(3) The dominant period of the 'excess' winter energy has been examined for four records only (two at NEADS-6) but seems to be highly variable between sites The 25-day and 12 5-day dominant peaks of excess winter energy in the u and v spectra at NEADS-6 (3,050 m) have already been described (Fig 4*a*) At 4,050-m depth on the NEADS-5 site the corresponding peaks are at 33 days and 50 days (Fig 4*b*) while at 2,049 m at mooring 'R' the excess winter energy is still increasing at the longest periods of the spectrum ($\geq$100 days, Fig 4*c*)

(4) In each case the dominant winter excess of energy occurs in the along-isobath component (u for NEADS-6, v for NEADS-5 and 'R') and although any association with topography may be coincidental the dominance of one component over the other appears least on the gentle slope of the continental rise (Fig 4*a*) and greatest on the steep continental slope In the latter case the winter excess of energy is almost solely in the along-slope component (Fig 4*c*)

(5) The apparent ~1-month phase-lag between the time variations of K_E in the upper layer and the deep water is supported in Fig 5, provided that the supposed link with wind stress is a valid (causal) one During July 1979–May 1980 deep current measurements to 4,710-m depth at NEADS-5 can be matched with wind stress at the neighbouring OWS ROMEO site (see Fig 1) At OWS ROMEO the winter wind stress peaked sharply in December 1979, 1 month before the K_E at depth rose to its winter maximum (Fig 5*c*–*e*)

(6) The supposed link between eddy kinetic energy and wind stress is given some credence by the general 'shape' of the curves in Fig 5 At all sites, depths and sampling periods shown, the time variation of K_E is surprisingly similar, following a broad summer minimum centred on September, the subsequent winter peak from January to April is characteristically bimodal, interrupted by a secondary minimum in February Curves of monthly mean noon windstress for the relevant years at OWS CHARLIE, LIMA and ROMEO and at Ponta Delgada, Azores (Fig 6) show that this midwinter 'dip' is also a characteristic feature of the windstress field in January/February

(7) To obtain some estimate of the seasonal contribution to the total kinetic energy of the long-term record, 1-yr records from the second deployment at NEADS-6 (3,050 m) and from 4,050 m at NEADS-5 were split into equal ~6-month periods representative of the quiescent summer and energetic winter periods. The total eddy kinetic energy per unit mass of the summer, winter and full-record time series was then calculated. At 3,050 m, NEADS-6, K_E(Rec)summer = 3.72 cm^2 s^{-2}, K_E(Rec) winter = 15.64 cm^2 s^{-2} and K_E(Rec) for the full record = 9.72 cm^2 s^{-2}, for 4,050 m, NEADS-5, the corresponding figures are 0.48, 1.39 and 1.02 cm^2 s^{-2} respectively. Thus the summer:winter eddy energy is in the ratio of 1:4.2 for the NEADS-6 record and 1:2.9 for that at NEADS-5. The corresponding ratios of summer:winter mean wind stress for 6-month periods, 1 month in advance of the current meter data, are 1:2.2 (LIMA) and 1:1.9 (ROMEO).

Theoretical mechanism

From reviews[10,11] of the known properties of linear wave propagation in a rotating stratified ocean we can identify possible driving forces for the seasonally-varying low-frequency oscillations that we have observed. Candidate mechanisms include (1) a response to local and/or remote forcing at the surface by wind and buoyancy effects, (2) instabilities and/or eddy-shedding over topography in a seasonally-varying mean flow, (3) instabilities of large-scale wave motions (such as planetary waves) driven by surface forcing, (4) propagation from equatorial regions of coastal or Kelvin waves on the eastern boundary which then propagate to the interior either directly as planetary waves or indirectly by following depth (h) or dynamical (f/h) contours as topographic or edge waves ($f = 2\Omega \sin \phi$, where Ω is the Earth's angular rate of rotation and ϕ is the latitude), (5) wave trapping by closed (f/h) contours.

Many of these theoretical mechanisms have been observed in the ocean but mechanism (1) appears be the most relevant in view of the close association with wind stress and stratification in our results. This mechanism was explored using an idealized model[12] which includes a crude representation of stratification, rotation, topography, coastal boundaries and surface wind forcing.

It is important to decide whether the observed waves are likely to be forced or free. The maximum frequency ($\omega_{\max}$) of a free planetary wave is

$$\omega_{\max} = -\tfrac{1}{2}\beta a$$

where β is the northward gradient of the Coriolis parameter and a is the local radius of deformation (that is the distance over which gravitational and rotational forces are balanced). Using baroclinic/barotropic to refer to depth dependent/independent behaviour, we find that for barotropic modes a is ~2,000 km at midlatitudes so that $\omega_{\max}$ corresponds to a period of 3.6 days. Thus barotropic waves could contribute to the observed oscillations but have no vertical dependence and so cannot account for the observed vertical structure. For a first baroclinic mode a is ~30 km and $\omega_{\max}$ corresponds to a minimum period of ~8 months. Thus the oscillations observed at 12–50-day periods cannot be free baroclinic planetary waves (similar calculations for other wave modes are more difficult to make without additional data). Therefore it was assumed that the observed oscillations are not free and we now discuss the forced response to wind. In the present model, the ocean is considered to have two layers of mean depth H_1 and H_2, ($H_1 \ll H_2$) with mean densities ρ_1 and ρ_2 ($\rho_1 < \rho_2$). The stratification is stable but unvarying. Rigid boundaries run north–south but none east-west. Any topography (of height T) is shallower than the lower layer thickness and does not vary north–south. The ocean is driven by an eastward windstress acting on the upper layer such that the response is periodic north–south. A full description of the model is given elsewhere[12].

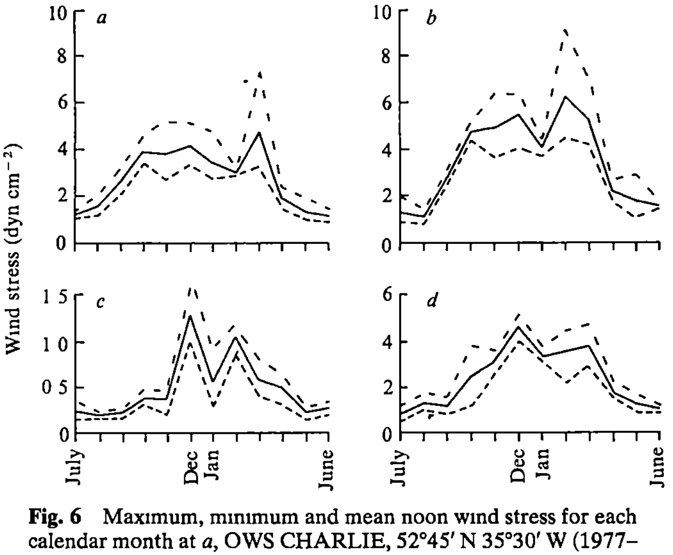

Fig. 6 Maximum, minimum and mean noon wind stress for each calendar month at *a*, OWS CHARLIE, 52°45′ N 35°30′ W (1977–79), *b*, OWS LIMA, 57° N 20° W (1978–80), *c*, Ponta Delgada, Azores (1977–79), *d*, OWS ROMEO, 47° N 17° W (1977–79).

In view of the depth-dependence of the observed oscillations our attention is focused on the equation in ref. 12 describing the baroclinic component of zonal flow. Initial runs using realistic input parameters but flat topography confirm that for the seasonal cycle the planetary wave can propagate, with a rapidly oscillating solution across the basin, but at the (lower) 'eddy' frequencies observed no propagation is possible and $|\hat{u}|$ (the magnitude of the zonal baroclinic component) is small away from the boundaries. The solution is almost purely barotropic as anticipated.

To see if topography orientated north–south can produce a distinct baroclinic signal, the calculation was repeated with topography varying sinusoidally east-west, with amplitude 1,500 m (in an ocean of depth 5,400 m) and wavelength 1,250 km. The results in ref. 12 show that in these circumstances the topographic effect must be unrealistically large to overcome the time-dependence effect and yield a sizeable baroclinic signal. The ratio of the topographic to time-dependent terms is dimensionally $g'Txl(H_1H_2^{-1})^2\omega^{-1}f^{-1}$, where g' is the reduced gravity, $[g(\rho_2-\rho_1)\rho_2^{-1}]$, Tx the topographic slope, and l the north–south wave number of the forcing. For the above parameters, this ratio is about 5×10^{-3}. However, the ratio can easily be increased, by steeper topography, a shorter north–south length scale, or by increasing H_1. All three of these effects are probably relevant in the eastern North Atlantic: the topographical variations can be quite rapid, the confused topography may well induce shorter north–south scales in the oceanic response, and, most encouragingly, the increase in eddy kinetic energy at depth does not occur until a seasonally-strengthening wind stress is accompanied by the breakdown of the seasonal thermocline (that is a rapid increase in H_1). Thus preliminary results from this simple model seem capable of reproducing a baroclinic signal at depth and at the observed eddy frequencies.

Discussion

There are many potential sources of error in the above type of analysis. The spectral analysis techniques are strictly valid only for stationary time series which is not the case in the 60-day pieces of record that were used. The current meter records themselves are relatively short, sparse or discontinuous and rarely provide concurrent full-depth coverage. On the link with wind stress, there is an obvious need for caution in exploring causality between time-series that are dominated by one narrow-band signal such as the seasonal cycle. With one exception, moorings are remote from the Ocean Weather Stations which provide the wind stress data, and although the degree of thermal stratification is thought to be important to the input of eddy energy to the deep ocean, time series of temperature in the upper ocean which define the breakdown and re-establishment of the stratification are very rare.

Nevertheless, the seasonal signal in fluctuation kinetic energy is plainly visible in time series which have been subjected to no more sophisticated processing than the application of a low-pass filter (for example, Fig 2*a*), and where spectral analysis has been used, the seasonal signal in K_E is so consistently shown over a wide range of sites, years and sampling depths as to suggest that it is both real and widespread, not merely an artefact of the analysis We conclude therefore that in the eastern North Atlantic, remote from the influence of the Western Boundary Current, eddy kinetic energy at all depths is principally some function of wind stress and stratification, generated during the winter and early spring, propagating to abyssal depths and decaying to a minimum in late summer If so a similar seasonal signal will probably be found to dominate other records from the eastern midlatitude oceans and may even be detectable within the fields of influence of the western boundary currents or further afield in the equatorial zone (A significant correlation between wind stress and deep ocean currents has recently been observed in the Atlantic North Equatorial Current, east of Barbados, at week to month time scales[13]) Note that the suggested mechanism seems to require some degree of bottom slope, a point which is apparently confirmed in the observations

The above conclusion is not meant to imply that mesoscale eddies as conventionally understood do not exist in the north-east Atlantic Plainly they do, as demonstrated by much direct and indirect evidence[14-16], but equally these random and presumably non-seasonal features are sufficiently sparse (or weak or shallow) to be undetectable against the dominant 'eddy' signal arising from wind stress. To paraphrase the conclusion of Bernstein and White for the north-east Pacific[17], the north-east Atlantic appears to be a 'near void' for mesoscale eddies This is a rather different conclusion to that of Wyrtki *et al*[18] who suggest, from their analysis of ship drift data "that the eddy motion in the ocean is generated in areas of strong mean shear flow and is subsequently distributed over the whole ocean with much less decay than the mean flow". The difference is important, however If the eddy climate of the eastern midlatitude ocean really is more properly described as a function of windstress and stratification than as the synthesis of random mesoscale events, then the problem of its parameterization in general circulation models should be simplified

Hydrothermal petroleum in mineralized mounds at the seabed of Guaymas Basin

Bernd R. T. Simoneit*

Peter F. Lonsdale

Marine Physical Laboratory, Scripps Institution of Oceanography, University of California at San Diego, La Jolla, California 92093, USA

Petroleum has been dredged from an active hydrothermal mound area in the southern rift of Guaymas Basin, Gulf of California This organic matter is composed of gasoline-range aliphatic and aromatic hydrocarbons and predominantly residual polar asphaltic material The aliphatic hydrocarbons of two bitumen samples have very different boiling range and composition Both samples contain polynuclear aromatic hydrocarbons and olefins, which indicate formation at pyrolytic temperatures. The overall compositional data indicate an origin from biological detritus by thermal alteration and rapid quenching by hydrothermal removal, followed by condensation at the seabed.

THE Guaymas Basin is an actively spreading oceanic basin, part of the system of spreading axes and transform faults that extend from the East Pacific Rise to the San Andreas fault system[1,2] The basin is tectonically very active and consists of two rift valleys, the northern and southern troughs, separated by a 20-km transform fault area The sediment blanket accumulates at a high rate (>1 m kyr^{-1}), keeping the basin floor covered, while the ocean plate accretion process occurs by dyke and sill intrusions into the unconsolidated muds[1,3] Both rifts have high conductive heat flow (locally exceeding 1 2 W m^{-2})[4,5]

Petroliferous gasoline-range hydrocarbons were reported in a gravity core from the northern trough and interpreted to be of a thermogenic origin[6] Interstitial gas, bitumen and kerogen analyses of samples from Deep Sea Drilling Project Sites 477 and 481 confirm the alteration of the indigenous organic matter by hydrothermal stress[3,7-10]

The samples discussed here are derived from a deep-tow plus heatflow survey cruise by Scripps Institution of Oceanography in 1980 Numerous hydrothermal mounds rising 20-30 m above the rift floor (water depth ~2,000 m) were mapped in the southern trough (Fig 1) and some had active hydrothermal plumes[11] Photographs showed encrusted mounds and columns covered with tubeworms and other fauna A dredge haul (7D, Fig 1) across a 50 m-wide patch of sinter deposits which form a mound recovered claystones, massive sulphides, barite, talc and other hydrothermal minerals, together with tubeworm specimens Many of the fragments in the dredge were stained with a petroleum-like oil and had a strong odour similar to diesel fuel

Several hand-specimens of these odorous, oil-stained samples were sealed in foil and glass jars, then analysed some months later to determine the nature, composition and source of the petroliferous material One specimen (7D-2B) is a massive sulphide with approximately equal proportions of sphalerite, chalcopyrite and pyrrhotite, and interstitial barite, the others are claystones

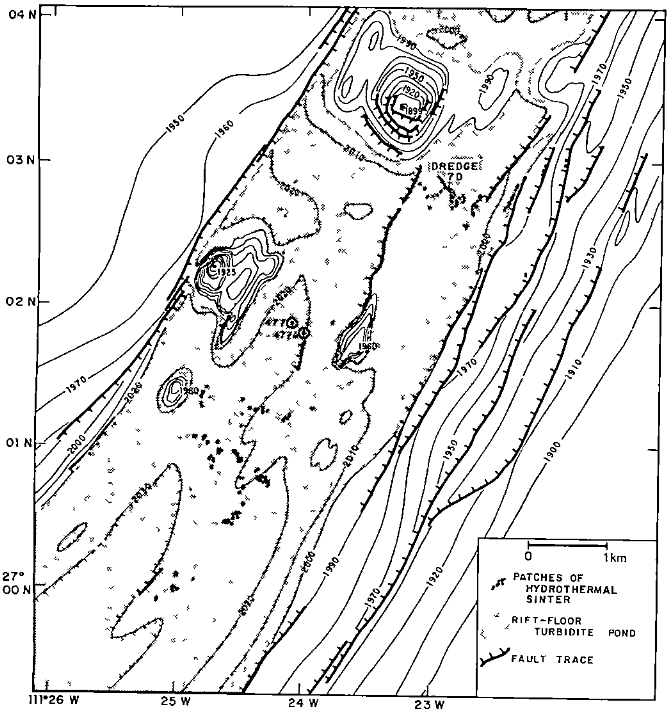

Fig. 1 Location map showing the dredge site (7D) and DSDP Site 477 in the southern rift of Guaymas Basin.

Experimental

Two of the dredge sub-samples (7D-3B and -5A, Fig. 1) were canned under water for analysis of the gasoline-range hydrocarbons as described[6]. A packed column (stainless-steel, 2 m × 2 mm i.d., 0.3% Carbowax 20M on Carbopac C) was used for the analytical gas chromatography (Hewlett–Packard Model 5830A). The injector temperature was at 200 °C and the temperature programme was 30 °C (1 min), 30–225 °C (5 min). The headspace in the cans was 150 cm^3 and the concentrations of the hydrocarbons are reported as ng cm^{-3} of headspace.

Two other dredge sub-samples (7D-2B and -4A, B, Fig. 1) were first extracted as received with methanol and methylene chloride (CH_2Cl_2). The aqueous phase was re-extracted with CH_2Cl_2 and the extracts were combined. The residue was subsequently crushed and extracted further with CH_2Cl_2, which was also combined with the initial extract. The total extracts were concentrated and aliquots were subjected to column chromatography on silica gel (column 1 × 17.5 cm). The samples were separated by elution with hexane (15 ml as F1), hexane/benzene (3:2, 25 ml as F2) and then methanol (20 ml as F3) into the respective fractions, which were analysed by capillary gas chromatography (GC) and gas chromatography–mass spectrometry (GC–MS). The total extracts were also quantified by weighing aliquots of dried extract (or fraction) on a microbalance.

The capillary GC analyses were carried out on a Hewlett–Packard Model 5830 GC with a fused silica capillary column (25 m × 0.20 mm i.d.) wall-coated with SP-2100. The operating conditions were as reported earlier[6]. The GC–MS analyses were conducted on a Finnigan Model 4000 quadrupole mass spectrometer interfaced directly with a Finnigan Model 9620 GC and equipped with a 30 m × 0.25 mm i.d. fused silica capillary column (wall-coated with SE-54). The operating conditions were as reported earlier[6]. The MS data were acquired and processed with a Finnigan-Incos Model 2300 data system. Compound assignments were made from individual mass spectra and GC retention times, with comparison to authentic standards where possible.

Results and discussion

The relative amounts of the major gasoline-range hydrocarbons of two dredge samples are listed in Table 1. Sample 7D-5A has a much greater amount of C_5–C_{10} hydrocarbons than sample 7D-3B and in both cases the concentrations of branched and cyclic compounds (possibly also olefins) far exceed the abundance of the normal hydrocarbons. The approximate total concentration of C_2–C_{10} hydrocarbons for sample 7D-5A is about 10 times greater than for the other sample. The relative distributions of all hydrocarbons are very similar for both samples in the range of C_5–C_{10}, but sample 7D-3B has only minor components from C_2 to C_5 (Table 1). The large amounts of C_2–C_{10} hydrocarbons and their structural diversity confirm their origin by thermal generation from the sedimentary organic matter[7].

The total bitumen (lipid) extract of sample 7D-2B is light amber in colour and black for sample 7D-4A, B, both extracts of the samples exhibit blue fluorescence in solution (Table 2). This colour is typical for (naphtha) heavy condensates and the concentrated extract for sample 7D-4A, B does exhibit a yellow fluorescence, indicating a major amount of heavier oil components. The total yield of bitumen is highest for sample 7D-4A, B and it contains only traces of elemental or organic sulphur. The 'light' bitumen (7D-2B), however, has a major proportion of elemental sulphur and also organic sulphur compounds (the minerals of this sample are massive sulphides). These two bitumens are clearly different, which is further substantiated by the following data. The hydrocarbon yields are found in Table 2, where the aliphatic fraction (F1) is lowest for both samples and most of the bitumen is comprised of asphaltic (F3) and then aromatic/naphthenic (F2) material. The aromatic-to-aliphatic ratio for sample 7D-2B is 9.3 and it is 4.7 for sample 7D-4A, B, typical for many crude oils[12].

The GC traces of the aliphatic hydrocarbons are given in Fig. 2 and they are dramatically different. Sample 7D-2B (Fig. 2*a*) exhibits a pattern typical of a petroleum, where the dominant *n*-alkanes, C_nH_{2n+2}, range from $n = 12$ to 33, with no carbon number predominance ($CPI_{12-33} = 1.03$) and a maximum at *n*-C_{21}. Carbon preference index (CPI) = odd carbon number *n*-alkanes/even over the range indicated for example,

$$CPI_H = \frac{2\Sigma \text{ odd } C_{13}\text{–}C_{33}}{\Sigma \text{ even } C_{12}\text{–}C_{30} + \Sigma \text{ even } C_{14}\text{–}C_{32}}$$

Pristane and phytane are about equal (Pr/Ph = 1.06). The complex, unresolved mixture of branched and cyclic hydrocarbons (that is, hump) ranges from C_{11} to C_{31}, also typical of petroleum. On the other hand, sample 7D-4A, B (Fig. 2*b*) exhibits a much narrower GC profile, skewed to lower carbon

numbers The dominant resolved peaks are various mono- and di-olefins ranging from C_{12} to C_{19} and the hump ranges from C_9 to about C_{21} This is very unlike typical petroleum, as olefins are not found in mature crudes[12,13] Olefinic hydrocarbons have been identified in a crude oil from Bradford, Pennsylvania[14] and they were found to consist of mid-chain normal, branched and cyclic analogues with the double bonds mainly in the *trans* configuration The presence of these olefins was accounted for by a process of natural thermal cracking followed by the rapid disappearance of *cis* and terminal olefins[14] The *n*-alkanes of sample 7D-4A, B are present as minor components and range from C_{10} to C_{23}, with essentially no carbon number predominance (CPI_{10-23} = 1 20) and a maximum at C_{15} Pristane is more abundant than phytane (Pr/Ph = 1 6)

The GC–MS data for sample 7D-2B (F1) confirmed the minor presence of a similar range of mono- and di-olefins ranging from C_{12} to C_{19} These compounds are not terminal olefins as were identified near the sills of DSDP site 481A (ref 9) They are slightly more stable 'in-chain' olefins with methyl branching, similar to those described by Hoering[14]

The major diagnostic molecular markers in this fraction consist of triterpenoids, extended diterpanes and steranes with their rearranged analogs (diasteranes) Their relative distributions are given in Fig 3 with an example of the corresponding compounds in unaltered lipids of shallow sediment from Guaymas Basin[6] The extended diterpanes (Fig 3*a*) range from C_{20} to C_{29} in a similar distribution pattern as observed for other mature petroleum samples[15] They are, however, not present in the unaltered surface sediments (for example, Fig 3*b*)[6,9] The triterpenoids (Fig 3*a*) are surprisingly 'mature', they are for the most part in their thermodynamically more stable form, completely different from unaltered lipids of surface sediments (for example, Fig. 3*b*) The triterpenoids are comprised primarily of the 17α(H), 21β(H)-hopane series ranging from C_{27} (no C_{28}) to C_{35} and the homologues from C_{31} to C_{35} are present as 22-S and R diastereomeric pairs in a ratio of about unity This series constitutes the stable mature form of these compounds[15–18] and seems to have been generated by the hydrothermal activity These compounds are not found in the unaltered sediments (for example, Fig 3*b*)[6,9] where the biogenic markers with the 17β(H), 21β(H) stereochemistry and various triterpenes predominate Minor amounts of 17β(H), 21α(H)-moretanes (C_{29}, C_{30} and C_{31}), 17β(H), 21β(H)-hopanes (C_{27} and C_{30}), *iso*-hop-13(18)-ene and 17β(H)-moret-22(29)-ene are also present in sample 7D-2B These are precursor relics and intermediates from the thermal conversion process

The steroidal markers consist of primarily 5α(H), 14α(H), 17α(H)-steranes (20 R), with lesser amounts of 5β(H), 14α(H),17α(H)-steranes (20 R) and diasteranes [mainly the 13β(H), 17α(H)-20 R or S series][17,19–21] The steranes ranged from C_{26} to C_{30}, with cholestane as the major homologue (Fig 3*c*) The distribution pattern indicates a marine autochthonous origin and fits best with similar data for DSDP Site 477 (ref 9) The large 5α(H)-sterane concentration is a result of the elevated thermal stress which probably converted other steroidal compounds to these hydrocarbons[9]

The extended diterpenoidal, triterpenoidal and steroidal indicator compounds are not detectable by GC–MS in the hydrocarbon fraction of sample 7D-4A, B This fraction is composed of more volatile, lower molecular weight compounds

The GC traces of the aromatic/naphthenic fractions (F2) of both samples are given in Fig 4 Again, the hump of unresolved material is skewed to the lower molecular weight region in the case of sample 7D-4A, B The GC–MS data indicate that the major resolved peaks are polynuclear aromatic hydrocarbons

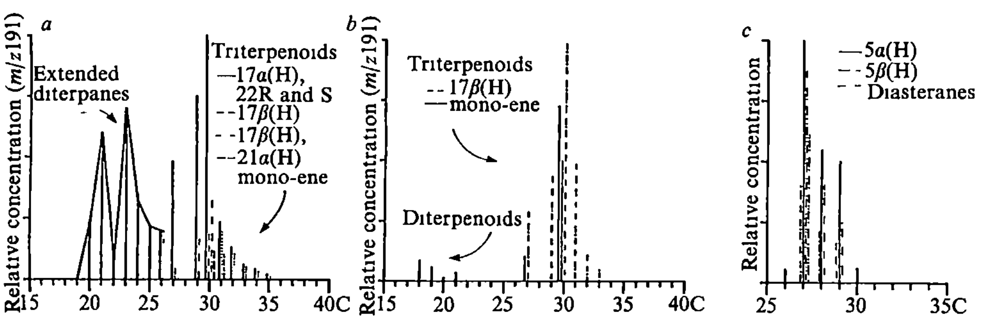

Fig. 3 Relative distribution diagrams for triterpenoids in *a*, sample 7D-2B, and *b*, an unaltered sample, station 30G, 3 5 m subbottom[6], and steranes in *c*, sample 7D-2B Relative concentrations are based upon GC responses and *m*/*z* 191 and 217 mass chromatograms

(PAH), another group of compounds uncommon in petroleums but ubiquitous in higher temperature pyrolysis residues (for example, smoke or from *in situ* organic matter)[12,22 23]

The major components that were identified and resolved are listed in Table 3 The concentrations (μg per g of total oil) of the major analogues are of the same order of magnitude for both samples The dominant analogues for both samples are the peri-condensed aromatic series as for example pyrene, benzopyrenes, perylene, benzoperylene and coronene These peri-condensed structures are more reactive than their angularly condensed analogues[22] Thus, they must have been expelled rapidly after genesis to the seabed for their preservation A further indication for a pyrolytic origin is the presence of five-membered alicyclic rings (such as acenaphthene, fluorene, and fluoranthene, Table 3) which are found in all pyrolysates from organic matter, because once formed they do not easily revert to peri-condensed aromatic hydrocarbons[22 23] Note also that this fraction contains significant amounts of toxic PAH The benzopyrenes are major components and the highly toxic benzo(*a*)pyrene is present at levels of 25 and 16 ng per g of total bitumen Perylene is present in these fractions and is also the dominant PAH in the unaltered sedimentary lipids of samples deposited in the Gulf from oxygen-minimum environments[9 24] Thus, the chemical composition of this fraction indicates a source from pyrolysis with rapid quenching by hydrothermal removal and subsequent condensation at the seabed

Conclusions

The thermogenic origin of the petroleum-like organic matter in the dredge samples has been confirmed This is based on the following chemical parameters (1) presence of gasoline range hydrocarbons (also the odorous compounds) (2) broad distribution of hydrocarbons (hump, C_{13}–C_{33}) and presence of pristane and phytane, and (3) the relative amounts of aromatic/naphthenic (F2) and asphaltic (F3) material versus the aliphatic hydrocarbons (F1)

The indications that these oils are derived from a higher temperature pyrolysis process rather than the normal petroleum genesis window (maximum ~ 150 °C)[12] are as follows first, the presence of peri-condensed PAH, and second, a large amount of asphaltic material and possibly the presence of various branched and in-chain olefins

Hydrothermal migration is suggested by the following data (1) the virtual absence of primary olefins (they were dominant components near sills at depth in for example DSDP Site 481A)[9], which are highly reactive and are not expected to survive migration in hot fluids, and (2) the same molecular marker fingerprint as *in situ* thermogenic bitumen at DSDP Sites 477 and 477A (ref 9) This is not a case of migration of mature petroleum from geologically old formations (>Quaternary) through the younger sequences, where it could have dissolved the indicators just discussed Such an explanation is inconsistent with the dramatic differences in boiling range for both the aliphatic and aromatic hydrocarbon fractions (F1 and F2) of the two samples It is more likely that a temperature gradient exists at the seabed away from the hydrothermal vent, which controls condensation and solution into ambient cold seawater of the emanating organic matter (oil) This needs further sampling in more controlled conditions

Another indication that these oils are derived from thermal alteration of the immature organic matter (Quaternary) in the basin is found in the minor biogenic marker residues Traces of 17β(H), 21β(H)-hopanes and triterpenes are present in sample 7D-2B and these compounds are not found in mature petroleum The distribution patterns of these molecular markers are very similar to examples from samples at depth (DSDP Sites 477 and 481)[9]

The sediments at depth (DSDP Sites 477, 478 and 481) contain large amounts of thermogenic (admixed with some original biogenic) interstitial gas[8 10], and also thermally derived bitumen[0] Thus, the presence of petroliferous condensate at the seabed indicates that the plume water must contain large amounts of methane and higher molecular weight organic matter This organic matter can represent a carbon source to microbes at the vent site, which in turn can be food for the higher fauna

We thank Captain A Phinney, the crew and scientific party of R/V *Melville* for their skill in collecting the samples, Mr E Ruth for GC–MS data acquisition, Mr Cary Jackson for the hydrocarbon gas analyses, and Ms Dara Blumfield and Ms Dana Blumfield for technical assistance Funding from the NSF (grant OCE 79-08811) is gratefully acknowledged

Cloning and sequence analysis of cDNA for bovine adrenal preproenkephalin

Masaharu Noda*, Yasuji Furutani*, Hideo Takahashi*, Mitsuyoshi Toyosato*, Tadaaki Hirose†, Seiichi Inayama†, Shigetada Nakanishi‡ & Shosaku Numa*

* Department of Medical Chemistry and ‡ Institute for Immunology, Kyoto University Faculty of Medicine, Kyoto 606, Japan
† Pharmaceutical Institute, Keio University School of Medicine, Tokyo 160, Japan

The nucleotide sequence of cloned cDNA for preproenkephalin from bovine adrenal medulla indicates that the precursor protein contains four copies of Met-enkephalin and one copy each of Leu-enkephalin, Met-enkephalin-Arg^6-Phe^7 and Met-enkephalin-Arg^6-Gly^7-Leu^8, a previously undetected opioid peptide. The enkephalin and extended enkephalin sequences are each bounded by paired basic amino acid residues. Preproenkephalin may represent a multi-hormone precursor, like the corticotropin–β-lipotropin precursor

METHIONINE-enkephalin (Met-enkephalin) and leucine-enkephalin (Leu-enkephalin) are endogenous pentapeptides with opiate-like activity which were originally discovered in the brain[1] The Met-enkephalin sequence is contained in the structure of β-lipotropin (β-LPH), which is regarded as a pituitary hormone We have previously purified the bovine mRNA coding for the common precursor of β-LPH and corticotropin (ACTH)[2] and have elucidated the primary structure of this precursor protein by determining the nucleotide sequence of cloned DNA complementary to the mRNA[3] Although β-endorphin, a 31-amino acid opioid peptide, which contains the Met-enkephalin sequence, has been shown to be produced from the ACTH-β-LPH precursor (alternatively designated preproopiomelanocortin) by post-translational processing, accumulating evidence indicates that Met-enkephalin itself is not derived from the same precursor (see ref 4 for review) Furthermore, several polypeptides containing Met-enkephalin and/or Leu-enkephalin sequences, and which are not related to β-endorphin, have recently been isolated from bovine adrenal medulla[5–11] Thus, these polypeptides have been suggested as intermediates in the biosynthesis of the opioid pentapeptides

In an attempt to elucidate the primary structure of the initial enkephalin precursor (hereafter referred to as preproenkephalin), we have now cloned DNA sequences complementary to the bovine mRNA coding for the precursor protein Nucleotide sequence analysis of the cloned cDNA has revealed the whole amino acid sequence of bovine preproenkephalin

Isolation of cDNA clones and strategy of DNA sequencing

The initial approach used to clone DNA sequences complementary to preproenkephalin mRNA was to screen a library of cDNA clones by hybridization with a mixture of synthetic oligodeoxyribonucleotides, the sequences of which represented all possible sequences predicted from a known partial amino acid sequence of an enkephalin-containing polypeptide The choice of appropriate hybridization conditions including temperature virtually eliminates the formation of mismatched duplexes without affecting the formation of perfectly matched ones, thus ensuring the selection of desired clones (Such a screening principle[12] would be useful for isolating cDNA clones that carry mRNA sequences present in low abundance) After isolating cDNA clones carrying a partial mRNA sequence and determining the nucleotide sequence of the cDNA, a synthetic oligodeoxyribonucleotide primer complementary to a portion of the determined mRNA sequence was elongated by reverse transcription of preproenkephalin mRNA The cDNA transcripts thus formed were cloned and screened by hybridization with an appropriate restriction fragment derived from initially isolated cDNA clones to yield clones carrying mRNA sequences upstream from the site corresponding to the synthetic primer used

Poly (A)-containing RNA was isolated from bovine adrenal medullas, and double-stranded cDNA was synthesized by reverse transcription of this RNA template using oligo (dT) as primer A cloned cDNA library was constructed by inserting the total cDNA population into the *Pst*I endonuclease cleavage site of the bacterial plasmid pBR322 with the use of poly(dG) poly(dC) homopolymeric extensions Two oligodeoxyribonucleotides, 5′-TCCATCCACCATTC-3′ and 5′-TCCATCCACCACTC-3′ (Fig 1*a*), were synthesized by the modified triester method[13] These tetradecamers represent the only two possible cDNA sequences corresponding to the unique pentapeptide sequence Glu-Trp-Trp-Met-Asp (excluding the

0028–0836/82/030202—05$01 00

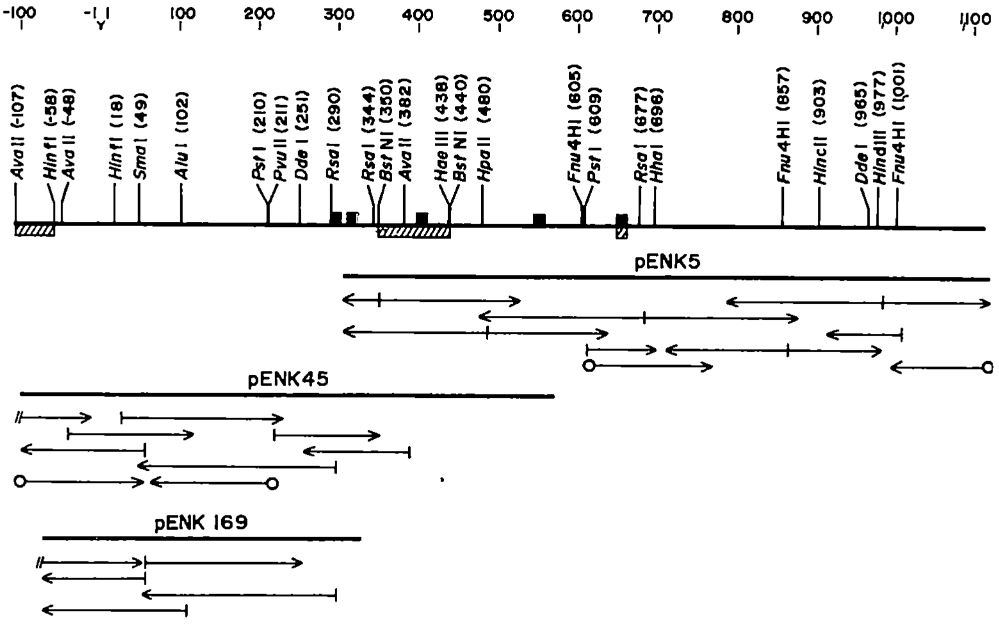

Fig. 2 Strategy for sequencing the cDNA inserts in the plasmids pENK5, pENK45 and pENK169 The clone pENK5 was isolated as follows Total RNA was extracted from bovine adrenal medullas, and poly(A)-containing RNA was isolated by oligo(dT)-cellulose chromatography according to the procedure used previously for the isolating of rat liver RNA[31] Single-stranded cDNA was synthesized by avian myeloblastosis virus reverse transcriptase (provided by Dr S W Beard), using 100 μg of poly(A)-containing RNA as described previously[32] The product was treated with alkali to remove the RNA template[33], and the second DNA strand was synthesized with *Escherichia coli* DNA polymerase I (Klenow fragment)[34] After treatment of the double-stranded cDNA with *Aspergillus oryzae* S_1 nuclease[35], homopolymeric poly(dC) tails were added to its 3′ ends by calf thymus terminal deoxynucleotidyltransferase[35] The poly(dC)-tailed cDNA was annealed to poly(dG)-tailed *Pst*I-cleaved pBR322 plasmid DNA[36] *E Coli* $\chi1776$[37] or HB101[38] was transformed with recombinant plasmids[39], and tetracycline-resistant transformants were screened by hybridization with the probe specified in the text[40], hybridization was carried out at 42 °C To isolate clones pENK45 and pENK169, single-stranded cDNA was synthesized with the specific oligodeoxyribonucleotide primers mentioned in the text as described by Houghton *et al*[41] The subsequent procedures were the same as described above, except that hybridization for selecting clones was conducted at 65 °C (pENK45) or 60 °C (pENK169) with the probes specified in the text The restriction map displays only relevant restriction endonuclease sites, which are identified by numbers indicating the 5′-terminal nucleotide generated by cleavage, for the nucleotide numbers, see Fig 3 The poly(dA) poly(dT) tract and the poly(dG) poly(dC) tails are not included in the restriction map, except the poly(dG) poly(dC) tails at the 3′ termini of pENK45 and pENK169, the location of these termini are approximate The sequences used for specific priming of reverse transcriptase are indicated by closed boxes, and those used as hybridization probes for selecting clones by shaded boxes DNA sequencing was carried out by the procedure of Maxam and Gilbert[14], 3′-end-labelling was conducted as described elsewhere[43] The direction and extend of sequence determinations are shown by horizontal arrows under each clone used The sites of 5′-end-labelling are indicated by short vertical lines at the end of arrows, and those of 3′-end-labelling (*Pst*I sites) by open circles at the end of arrows The slash marks at the end of arrows indicate that the site of 5′-end-labelling was the *Alu*I site on pBR322 plasmid DNA 56 bp from the *Pst*I site flanking the cDNA insert[43] Further details of the sequencing procedures have been described previously[3]

third nucleotide residue of the Asp codon), which is known to be a partial sequence of the enkephalin-containing polypeptides from bovine adrenal medulla, BAM-22P (ref 8), BAM-20P (ref 8) and peptide I (ref 10) An equimolar mixture of the two oligodeoxyribonucleotides was labelled with ^{32}P at the 5′ end and used as a hybridization probe to screen for recombinant plasmids carrying DNA sequences complementary to preproenkephalin mRNA Nineteen hybridization-positive clones were isolated from about 190,000 transformants On restriction endonuclease analysis, at least six of them exhibited a common restriction fragment of 68 base pairs (bp) which corresponded to the *Pst*I(609)-*Rsa*I(677) fragment containing the coding region for Glu-Trp-Trp-Met-Asp (Fig 2), as inferred from possible coding sequences for the known amino acid sequence of peptide I[10] Clone pENK5, which carried the largest cDNA insert, was subjected to nucleotide sequence analysis by the procedure of Maxam and Gilbert[14] according to the strategy indicated in Fig 2 (see Fig 2 legend for experimental details of cloning)

Because clone pENK5 (carrying nucleotide residues 297-1,113 given in Fig 3) evidently did not contain the entire protein-coding sequence, a further attempt was made to isolate cDNA clones carrying the remaining mRNA sequence For this purpose, one of the above-mentioned synthetic oligodeoxyribonucleotides, 5′-TCCATCCACCACTC-3′, the sequence of which was shown by DNA sequencing of the clone pENK5 to encode the amino acid sequence Glu-Trp-Trp-Met-Asp, was used for specific priming of the reverse transcription of preproenkephalin mRNA, poly(A)-containing RNA from bovine adrenal medulla served as a template The transcripts formed by elongation of the primer were converted to double-stranded cDNA, which was cloned in plasmid pBR322 and screened by hybridization with the *Bst*NI(350)-*Bst*NI(440) fragment (Fig 2) ^{32}P-labelled by nick translation[15] Out of ~1,200 transformants, two hybridization-positive clones were isolated which shared an internal *Pst*I site (position 210) located upstream of the other internal *Pst*I site (position 609) present in pENK5 (Fig 2) One of these clones, pENK45, which carried a larger cDNA insert, was subjected to DNA sequencing according to the

Numbers next to codons indicate the numbers of amino acids using particular codons The different numbers given for the Glu codons are due to the difference in residue 267 between the clones pENK45 and pENK169 strategy shown in Fig 2, it contained a sequence of at least 85 bp identical to that present in clone pENK5

To confirm the nucleotide sequence in the region upstream of that encoding enkephalins, we attempted to isolate additional clones carrying sequences in the 5′-terminal region, using cDNA species synthesized with another oligodeoxyribonucleotide primer which corresponded to sequences encoding Met-enkephalin Analysis of the nucleotide sequences determined for clones pENK5 and pENK45 had shown that the coding sequences for the four Met-enkephalin sequences located on the amino-terminal side of the deduced preproenkephalin structure are complementary to either oligodeoxyribonucleotide 5′-CATGAAGCCCCCAT-3′ or 5′-CATGAAGCCCCCGT-3′ (Fig 1*b*) Therefore, we used a mixture of these two oligodeoxyribonucleotides synthesized simultaneously[13] as a specific primer for reverse transcription of preproenkephalin mRNA The cDNA transcripts thus formed were cloned in the plasmid pBR322 as described above From ~100,000 transformants, one clone (pENK169) hybridizing with the *Ava*II(−107)-*Hin*fI (−58) fragment (5′-end-labelled at the *Hin*fI site) was isolated and subjected to DNA sequencing (Fig 2) Clone pENK169 shared a sequence of at least 371 bp with clone pENK45, except that the residues at positions −44 and 267 in pENK169 were C and G, respectively, instead of G and A in pENK45, the latter substitution in the protein-coding region leads to a synonymous codon The observed nucleotide differences may be due to possible polymorphism in the bovine preproenkephalin gene or to possible errors occurring during *in vitro* cDNA synthesis or DNA cloning

Nucleotide sequence of preproenkephalin mRNA and assignment of protein sequence

The primary structure of bovine preproenkephalin mRNA (Fig 3) was deduced from the 1,222-nucleotide sequence (excluding the poly(dA) poly(dT) tract and poly(dG)·poly(dC) tails) determined for the cloned cDNA inserts in the plasmids pENK5, pENK45 and pENK169 The nucleotide sequence was determined on both strands of the cDNA for all but 113 residues in the 3′-terminal region The sequences of nucleotide residues 310–411 and 574–690 correspond precisely to the amino acid sequences determined for peptide F[9] and peptide I[10], respectively, provided that the third (Thr) and the eighth (His) residues of peptide I are interchanged Furthermore, the sequences of nucleotide residues 697–729 and 763–789 match the partial amino acid sequences determined for peptide B[10] The codon for the phenylalanine residue at the carboxyl terminus of peptide B is followed by the translational termination codon UAA Thus the 3′-untranslated region of the mRNA is 324 nucleotides long (excluding the poly(A) tract) All three polypeptide sequences mentioned above, as well as the sequences of Met-enkephalin, Leu-enkephalin and Met-enkephalin with a carboxyl extension of Arg-Phe (Met-enkephalin-Arg^6-Phe^7), are each bounded by paired basic amino acid residues (except at the carboxyl terminus of preproenkephalin)

In assigning the amino acid sequence of the cryptic portion of preproenkephalin, the reading frame of amino acid codons was determined by the frame corresponding to the amino acid sequences of the known polypeptides Thus, an as yet unknown polypeptide of 50 amino acids containing the opioid octapeptide Tyr-Gly-Gly-Phe-Met-Arg-Gly-Leu (Met-enkephalin-Arg^6-Gly^7-Leu^8) at its carboxyl end was identified between peptides F and I Both the polypeptide and octapeptide within are bounded by paired basic amino acid residues Peptide F is connected by Lys-Arg with the preceding polypeptide which contains a Met-enkephalin sequence at its carboxyl end This Met-enkephalin sequence is also flanked by paired basic residues

The translational initiation site was assigned to the methionine codon AUG at positions 1–3 because this is the first AUG triplet that appears downstream from the nonsense codon UGA (residues −96 to −94) found in frame This assignment seems plausible because the sizes of the specific cDNA transcripts formed by reverse transcriptase-mediated elongation of

Fig 3 Primary structure of bovine preproenkephalin mRNA The nucleotide sequence of the mRNA was deduced from those of the cDNA inserts in the plasmids pENK5, pENK45 and pENK169, the nucleotide residues −44 and 267 given have been taken from pENK45, whereas those of pENK169 are C and G respectively (see the text) Nucleotide residues are numbered in the 5′ to 3′ direction, beginning with the first residue of the AUG triplet encoding the initiative methionine, and the nucleotides on the 5′ side of residue 1 are indicated by negative numbers The 5′-terminal sequence presented does not extend to the 5′ end of the mRNA (see the text), whereas the 3′-terminal sequence shown is followed by a poly(A) tract of 12 nucleotides, thus apparently representing the complete sequence of this region The predicted amino acid sequence is displayed above the nucleotide sequence, and amino acid residues are numbered beginning with the initiative methionine The sequences of Met-enkephalin, Leu-enkephalin and Met-enkephalin with a carboxyl extension, which are each bounded by paired basic amino acid residues (or by the carboxyl terminus of preproenkephalin), are boxed

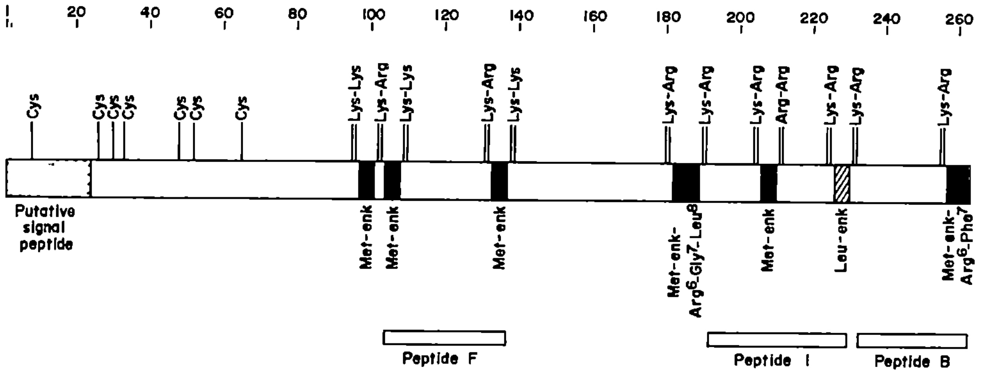

Fig 4 Schematic representation of the structure of bovine preproenkephalin The sequences of Met-enkephalin, Met-enkephalin-Arg^{6}-Phe^{7} and Met-enkephalin-Arg^{6}-Gly^{7}-Leu^{8} are indicated by closed boxes, the sequence of Leu-enkephalin by a shaded box and the putative signal peptide by a stippled box All the paired basic amino acid residues and cysteine residues are shown Amino acid numbers (see Fig 3) are given above The known peptide structures, peptide F (residues 104–137), peptide I (residues 192–230) and peptide B (residues 233–263), are displayed underneath by open bars, the known peptides representing partial sequences of peptide I—peptide E (residues 206–230), BAM-22P (residues 206–227), BAM-20P (residues 206–225) and BAM-12P (residues 206–217)—are not shown

the *Ava*II(−107)–*Hin*fI(−58) and *Ava*II(−48)–*Hin*fI(18) fragments (Fig 2) derived from the 5′-terminal region of the clone pENK45 suggest that no more than ~65 nucleotides are missing from the cloned sequence shown in Fig 3 Furthermore, the first 24 residues starting with the putative initiative methionine (residue 1) include many hydrophobic amino acids (19 nonpolar residues including 7 leucines) Because the signal peptide characteristic of secretory proteins[16] generally contains a region rich in hydrophobic amino acids with large side chains in its central portion and terminates in a residue with a small neutral side chain[17] (for example, alanine, glycine or serine), a possible site for cleavage of the signal peptide of preproenkephalin seems to be after the alanine at position 24 Assuming that the cysteine residue at position 8 is eliminated with the signal peptide, the remaining prohormone would contain six cysteine residues, all of which are located in its amino-terminal region Other peptide hormones, such as insulin and growth hormone, contain an even number of cysteine residues which form disulphide bonds[18]

The structure of bovine preproenkephalin is schematically illustrated in Fig 4 The precursor protein is composed of 263 amino acid residues, having a calculated molecular weight of 29,786 It contains four copies of Met-enkephalin and one copy each of Leu-enkephalin, Met-enkephalin-Arg^{6}-Phe^{7} and Met-enkephalin-Arg^{6}-Gly^{7}-Leu^{8} The amino-terminal region of the prohormone contains cysteine residues and is preceded by a putative signal peptide There is no structure corresponding to α-neo-endorphin[19] or dynorphin[20], both of which contain a Leu-enkephalin sequence The sequences of Met-enkephalin, Leu-enkephalin, Met-enkephalin-Arg^{6}-Phe^{7} and Met-enkephalin-Arg^{6}-Gly^{7}-Leu^{8} are each bounded by paired basic residues, Lys-Arg, Lys-Lys or Arg-Arg (except at the carboxyl terminus of preproenkephalin), implying that these enkephalins with and without a carboxyl extension can be formed by proteolytic processing of the precursor molecule[17] It is also possible that larger enkephalin-containing peptides do not merely represent intermediates in the formation of the opioid peptides of 5–8 amino acids, but possess specific physiological functions[7 8 10 11] A survey of various prohormones suggests that the Lys-Arg pair may be a primary site of proteolytic cleavage[3 17 21–23] Assuming that this is valid for proenkephalin and that the signal peptide is cleaved after the alanine residue at position 24, the primary products formed by proteolytic processing of proenkephalin would be peptides composed of residues 25–101, 104–130, 133–179, 182–189, 192–203, 206–223, 226–230, 233–254 and 257–263, it is possible that the glycine residue at position 130 is eliminated to amidate the preceding leucine residue[3 24] These products include Leu-enkephalin, Met-enkephalin-Arg^{6}-Phe^{7} and Met-enkephalin-Arg^{6}-Gly^{7}-Leu^{8} All the remaining Met-enkephalin-containing polypeptides, except the amino-terminal peptide, would have an enkephalin sequence at their amino-terminal end, as is the case for β-endorphin, α-neo-endorphin and dynorphin This processing pattern seems to be consistent with the known opioid activities of the larger enkephalin-containing peptides[7 8 11] Those with an enkephalin sequence at their amino-terminal end, such as peptide E[11], BAM-22P[8] and BAM-20P[8], but not peptide F[9], exhibit potent opioid activity It is conceivable that the peptide sequence next to the enkephalin portion of a large opioid peptide may modify the latter's physiological activity by conferring additional specificity for recognition of cell surface receptors, by increasing the binding affinity or by affecting its stability *in vivo* Furthermore, the activity of a large opioid peptide may be modified by glycosylation, the sequence Asn-Ser-Ser at positions 149–151 is a possible glycosylation site[25]

Note that the structural organization of preproenkephalin resembles that of the ACTH–β-LPH precursor[3] Both precursor proteins are composed of multiple repetitive units connected with a cysteine-containing amino-terminal sequence preceded by a signal peptide We have previously proposed that the different component peptides of the ACTH–β-LPH precursor, acting coordinately in the central nervous system as well as in peripheral tissues, may be involved in the defence mechanism of the living organism and that the biological significance of a multi-hormone precursor may be to produce multiple peptides with coordinate functions[3 26] Assuming that the enkephalin-containing component peptides of preproenkephalin perform relatea but different physiological functions, their coexistence with catecholamines in the chromaffin granules of adrenal medullary cells[5 27] seems to support the view that they are involved in conditions of acute stress Thus, preproenkephalin may represent another multi-hormone precursor from which different peptides are elaborated by proteolytic processing to function coordinately in the central nervous system and in peripheral tissues

Characteristic features of preproenkephalin mRNA

Computer analysis of the nucleotide sequence of preproenkephalin mRNA reveals that there are, in addition to the coding regions for the enkephalin sequences, many segments that seem to represent direct duplications (for example, residues 29–43 and 50–64, 121–136 and 807–822, 195–207, 462–474 and 597–609, 237–253 and 800–816, 352–367 and 421–436) This suggests that the structural gene for preproenkephalin has evolved by a series of direct duplications of certain common ancestral DNA segments followed by substitution, addition or deletion of some regions A large number of direct duplications was also observed for mRNA coding for the ACTH–β-LPH precursor[3]

Codon utilization for preproenkephalin mRNA, like other eukaryotic mRNAs[28], occurs nonrandomly (Table 1) Specific codon choices are preferred for some amino acids, generally reflecting a preference for G or C in the third position of the codons

The translational termination codon UAA is followed by eight in-frame nonsense codons (residues 814–816, 898–900, 907–909, 919–921, 1,066–1,068, 1,084–1,086, 1,090–1,092 and 1,093–1,095) Two copies of the sequence AAUAAA (residues 1,064–1,069 and 1,091–1,096) are present in the 3′-untranslated region, the latter being located about 20 nucleotides upstream from the poly(A) tract This sequence, which commonly occurs at the equivalent position of eukaryotic mRNAs[29], is probably involved in poly(A) addition after transcription

After completion of this work, Gubler *et al*[30] published the sequence of 45 nucleotides of bovine adrenal preproenkephalin mRNA (residues 613–657) encoding a partial sequence of peptide I Their data, which were obtained by sequencing a cDNA transcript formed by reverse transcriptase-mediated elongation of a specific oligonucleotide primer corresponding to the sequence Trp-Trp-Met-Asp-Tyr-Gln, differ from ours in two residues (G for residue 648 and T for residue 627)

We thank Dr Tatsuo Ooi for his help in computer analysis of the nucleotide sequence, and Miss Michiko Asai for assistance in the synthesis of oligodeoxyribonucleotides This investigation was supported in part by research grants from the Ministry of Education, Science and Culture of Japan, the Mitsubishi Foundation and the Japanese Foundation of Metabolism and Diseases

Molecular cloning establishes proenkephalin as precursor of enkephalin-containing peptides

Molecular cloning and DNA sequencing have yielded considerable structural information about proenkephalin All previously characterized intermediate peptides of the enkephalin pathway in bovine adrenal medulla have now been aligned into an unambiguous primary structure Two basic amino acid residues serve as processing signals for release of each of the different components

ADRENAL medulla, brain and intestinal mucosa from a variety of animal species possess enkephalin-containing polypeptides (ECPs) in addition to free enkephalin[1–3] Ten to twelve ECPs, ranging in molecular weight (M_r) from ~500 (0 5K) to 12K, have been purified to homogeneity from beef adrenal medulla, many of these have been completely sequenced, others only partially[3–8] It has been suggested that these peptides are intermediates in a biosynthetic pathway starting with 'proenkephalin'[9] This protein has not yet been purified to homogeneity, but is known to have a M_r of 40–50K and to contain one Leu- and six or seven Met-enkephalin sequences[9] Such a protein precursor is a likely candidate for the primary translation product in the enkephalin biosynthetic pathway To avoid the problem of purification and sequencing of such a large and scarce protein, we cloned and sequenced proenkephalin mRNA and deduced the primary structure of the protein from its DNA sequence A previous report[10] of the partial characterization of proenkephalin mRNA included a limited nucleotide sequence analysis which clearly established the presence of mRNA sequences encoding a previously described Met-enkephalin-

Fig. 1 The amino acid sequence and corresponding mRNA nucleotide sequence of one of the bovine adrenal ECPs (peptide I) that was used to derive the synthetic decahexamer described in ref 10 Note that DNA sequencing has allowed us to correct two errors in the published[4] amino acid sequence of peptide I residue 3 has been changed to a histidine, residue 8 to a threonine The top line shows the structure of peptide I and the middle line shows the derived mRNA sequence for the region of interest Note the extremely low degeneracy of the codons The synthetic decahexamer is shown at the bottom

containing polypeptide The mRNA was estimated to be 1,400–1,500 nucleotides long (consistent with a protein of 40–50K) and to represent 0 1% of the total poly(A^+)RNA in beef adrenal medulla

We now report the primary structure of most of the proenkephalin molecule as deduced from nucleotide sequences of cDNA clones These data show unequivocally that a proenkephalin containing at least six Met-enkephalins and one Leu-enkephalin is indeed the initial product of translation in the enkephalin biosynthetic pathway

Cloning and sequencing strategy

Total poly(A^+)RNA from bovine adrenal medulla was transcribed into double-stranded cDNA and molecules >8S were inserted into the *Sph*I restriction site of the plasmid pBR322 by the GC-tailing technique[11] Recombinant plasmids containing ~300 ng of cDNA were then introduced into *Escherichia coli* RR1 by transformation, resulting in ~70,000 clones[11] Clones were screened by the Hanahan–Meselson colony hybridization procedure[12] A synthetic decahexanucleotide was used as the radioactive probe The sequence of this probe was predicted from the available amino acid sequence of one of the characterized ECPs (Fig 1) This probe has also been used in the partial characterization of proenkephalin mRNA as described elsewhere[10] The conditions for hybridizing the decahexamer directly to colony-bearing filters were identical to those used for probing RNA blots[10] Twelve positive clones were obtained after initial screening of ~15,000 recombinants The plasmid DNA of each of these recombinants was analysed and the largest cDNA insert (1 kilobase (kb)) was sequenced using the technique developed by Messing *et al*[13] This cDNA insert proved to be a copy of proenkephalin mRNA incomplete with respect to the 3′ and 5′ ends Knowledge of its sequence, however, allowed us to select another of the recombinants that contained the complete 3′ end and its sequence was established as above The cloning and sequencing of the rest of the mRNA is in progress and will be reported in detail elsewhere

Structure of proenkephalin deduced from DNA sequencing

We used recombinant DNA technology in conjunction with microprotein chemistry to establish the structure of the major part of proenkephalin Several of the ECPs comprising proenkephalin have been isolated and their amino acid sequences determined[3–8] The nucleotide sequence of the partial cDNA clones has now allowed the alignment of these ECPs into an unambiguous primary structure and elucidated the amino acid sequences that link them (Fig 2) All the ECPs previously reported from the adrenal gland are represented in the cloned DNA sequences, which clearly establishes that proenkephalin is their common precursor (Fig 3) The largest ECP found (12 6K, Fig 3) actually extends beyond the 5′ terminus of the largest cDNA analysed The total size of the proenkephalin segment characterized in these combined studies is 27 3K, the initial translation product is certainly larger Earlier experiments[10] estimated proenkephalin mRNA to be 1,400–1,500 nucleotides long and we have accounted for ~1,000 of these in the sequence described here Therefore, we can estimate proenkephalin to be no larger than ~40K Cloning and sequencing of the 5′-terminal region of the mRNA should resolve this issue and also determine whether proenkephalin contains additional enkephalin sequences

The sequence of the proenkephalin cDNA indicates that each isolated ECP is flanked by two basic amino acid residues (Lys-Lys, Lys-Arg, Arg-Arg), demonstrating that the ECPs purified from the bovine adrenal medulla are immediate products of proenkephalin processing rather than artefacts of isolation The arrangement of two basic amino acid residues is known to be a typical prohormone processing signal[14] Moreover, each of the seven enkephalins in the precursor is preceded immediately by these processing signals, thus the N-terminal tyrosine of each of

Fig. 2 Complete nucleotide sequence and derived amino acid sequence for the 27 3K ECP The enkephalins are underlined, with the flanking basic amino acids boxed * Octapeptide, Met-enkephalin-Arg^6-Gly^7-Leu^8, ** heptapeptide, Met-enkephalin-Arg^6-Phe^7 (see text) Note that the DNA sequence obtained from the clone does not cover the entire amino acid sequence of the largest ECP The stop codon is underlined, as is the sequence AATAAA in the 3′-untranslated region of the mRNA

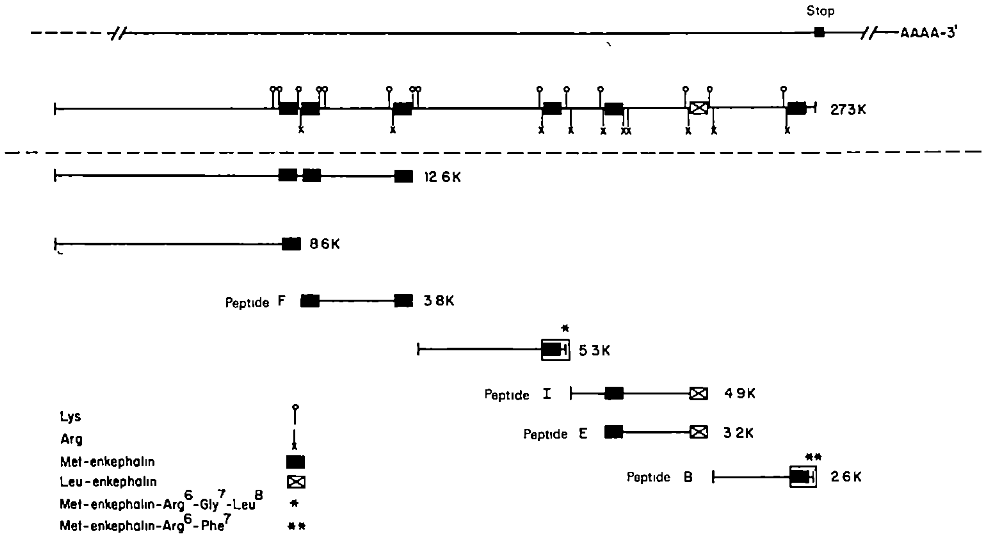

Fig. 3 Partial structure of proenkephalin and its processing At the top is shown schematically the cDNA clone, the next line represents the deduced primary structure of the 27 3K length of proenkephalin Below the broken line are shown the various ECPs whose structures are known K represents M_r of 1,000

the enkephalins, which is required for opioid activity[15], is exposed in these partially processed ECPs

Five of the enkephalins (four Met- and one Leu-enkephalin) are also immediately bounded on the C-terminal side by two basic amino acid residues, indicating that they are ultimately destined to be released as pentapeptides As mentioned above, however, they have also been isolated as parts of large ECPs from adrenal medulla (Fig 3) This observation indicates that, differential processing of proenkephalin and ECPs may occur in the tissue

Two of the Met-enkephalin peptides in proenkephalin are probably not processed to pentapeptides This is indicated by the presence of additional amino acid residues between the C-terminus of the enkephalin and the dibasic amino acid processing sites, for example, the heptapeptide Met-enkephalin-Arg^6-Phe^7, which occurs at the carboxy-terminus of the precursor This heptapeptide is found in the adrenal medulla evidently as a result of processing from proenkephalin at the Lys-Arg signal preceding the peptide It had previously been placed at the carboxy-terminus of proenkephalin because a chymotrypsinlike cleavage at the phenylalanine seemed an unlikely processing event[4] In certain assays, Met-enkephalin-Arg^6-Phe^7 has higher biological activity than free enkephalin[16], as does peptide E[7] Processing of proenkephalin also releases a Met-enkephalin Arg^6-Gly^7-Leu^8 peptide The presence of this octapeptide in adrenal medulla[8] reinforces the validity of this processing mechanism These data suggest that intermediates in the enkephalin pathway may be physiologically important and that proenkephalin yields more than free enkephalins alone

Two technical points need further comment We have not been able to substantiate the previous findings of a compound Leu-enkephalin-Arg^6 (ref 2) Due to low yields after isolation, however, this particular hexapeptide was never purified to homogeneity[2] DNA sequencing now clearly establishes that the Leu-enkephalin sequence is followed by a lysine Comparison of the partial sequence from proenkephalin mRNA reported earlier[10] with the sequence given here shows two discrepancies, but these do not alter the deduced amino acid sequence The earlier sequencing was performed on cDNA transcripts of total adrenal mRNA from several animals, the cDNA clone used here is a copy of only a single mRNA molecule Therefore, these discrepancies could reflect some polymorphism in the proenkephalin gene among the bovine population or the presence of multiple proenkephalin genes per genome

Two other ECPs found in hog tissue, dynorphin[17] and α-neo-endorphin[18], are also extensions of enkephalin at its carboxy terminus and are known to have much greater biological activity than the free enkephalins These peptides are probably products of a different ECP processing pathway as they show no apparent homology with any region of proenkephalin analysed so far except in the enkephalin sequences which they have in common However, the adrenal heptapeptide Met-enkephalin-Arg^6-Phe^7 is found in brain and intestine as well as in guinea pig adrenal gland[19] The tissue distribution of proenkephalin biosynthesis has yet to be determined, as is the origin of this heptapeptide in tissues other than the adrenal gland

β-Endorphin represents another ECP, produced in the anterior pituitary gland[20], that has enhanced biological activity relative to free Met-enkephalin, like peptide E and the heptapeptide from proenkephalin Indeed, the carboxyl extensions that distinguish these molecules may serve several roles, including that of stabilizing them against degradation, or in targeting

Proenkephalin is a unique precursor in that it contains several copies of a biologically active peptide, each in a different amino acid sequence context Complete processing of the precursor yields several enkephalins and larger ECPs The isolation of larger ECPs that are partial products of proenkephalin processing indicates that the full potential of a multivalent precursor of this kind to yield a diversity of ECPs is probably realized *in vivo*

Multiple arrangements of viral DNA and an activated host oncogene in bursal lymphomas

Gregory S. Payne*, J. Michael Bishop† & Harold E. Varmus†

Department of Biochemistry and Biophysics* and Department of Microbiology and Immunology†, University of California, San Francisco, California 94143, USA

Proviruses of avian leukosis virus (ALV) are located in the vicinity of a putative cellular oncogene (c-myc) *in ALV-induced bursal lymphomas. Enhanced expression of* c-myc *occurs in association with proviruses found in any of three configurations: (I) on the 5′ side ('upstream') of* c-myc *in the same transcriptional orientation; (II) on the 3′ side ('downstream') of* c-myc *in the same orientation; (III) upstream, in the transcriptional orientation opposite to that of* c-myc. *Thus, activation of adjacent cellular genes by retroviral DNA can involve mechanisms other than provision of a transcriptional promoter.*

AVIAN leukosis viruses (ALVs) are replication-competent retroviruses which lack transforming genes but cause tumours, most commonly bursal (B lymphocyte) lymphomas, after a lengthy latent period[1,2]. Three recent observations indicate that tumour induction by ALVs may depend on activation of cellular genes by proviral DNA, rather than on expression of viral genes. First, all bursal lymphomas are clonal populations of tumour cells containing at least one ALV provirus[3–6], but solitary proviruses are often defective and many tumours are devoid of normal virus-specific mRNAs[4,5]. Second, in most ALV-induced bursal lymphomas, proviral DNA is found in the same region of the host genome[4,5]; Hayward *et al.* have identified this locus as *c-myc*[7], the cellular homologue of the putative transforming gene (*v-myc*) of myelocytomatosis virus-29 (MC-29)[8,9]. Third, many tumours contain unusual species of polyadenylated RNA which anneal with cDNA specific for the U5 domain of the long terminal repeat (LTR) in proviral DNA (cDNA$_{5'}$, see Fig. 1*c*), but not with other viral probes[4,5]. These novel RNAs, presumed to be initiated in proviral LTRs and extended into flanking cellular DNA, appear to contain *c-myc* sequences and are many times more abundant than the usual transcriptional product of the *c-myc* locus[7].

Hayward *et al.*[7] reported that 31 of 37 lymphomas contained proviral DNA linked to *c-myc*, and the structures of proviral DNA and RNA in many of these tumours were consistent with a model in which the abundant *c-myc* transcripts were initiated within a proviral LTR positioned upstream from *c-myc* in the same transcriptional orientation. Six tumours did not show enhanced expression of *c-myc*. On the basis of these findings, it was proposed that a 'promoter insertion' mechanism operates to enhance expression of cellular oncogenes such as *c-myc* during ALV tumorigenesis.

In our previous study of four defective ALV proviruses in bursal lymphomas[4], all seemed to be located in the same region of the host genome, but two (from tumours LL1 and LL4) were in one orientation with respect to flanking DNA and two (from tumours LL2 and LL3) were in the opposite orientation. Further analysis of the tumour DNAs with probes for *c-myc* has shown that all four proviruses are located in or near the *c-myc* locus, upstream from sequences homologous to *v-myc*. The two proviruses (in LL1 and LL4) which conform to the promoter insertion model were associated, as predicted, with RNA species detectable with cDNA$_{5'}$, but similar species were not observed in LL2 or LL3 in which the proviruses and *c-myc* had opposite transcriptional orientations.

The findings with LL2 and LL3 were thus inconsistent with a promoter insertion mechanism and suggested that other kinds of regulatory events might occur in the apparent oncogenic collaboration between proviral DNA and *c-myc*. We have therefore surveyed additional ALV-induced lymphomas for the disposition of proviral DNA with respect to *c-myc* and for the composition of ALV and *c-myc*-related RNA. Our results demonstrate that at least three arrangements of proviral DNA in the *c-myc* locus are associated with enhanced levels of *c-myc* RNA: one of these arrangements is consonant with a promoter insertion mechanism but the other two—viral DNA downstream from *c-myc* in the same orientation and viral DNA upstream from *c-myc* in the opposite orientation—imply that hypotheses other than promoter insertion are required to account for the enhancement phenomena.

Strategies for studying *c-myc* activation

We have used restriction mapping procedures described by us previously[4] (see Fig. 1*c*) to characterize the structure of ALV proviruses and their integration sites in 12 chicken bursal lymphomas and 4 lymphoid cell lines. Cloned restriction fragments from the *v-myc* region of MC-29 viral DNA (see Fig. 1*b*) served as additional hybridization reagents for determining the location and transcriptional orientation of ALV proviruses with respect to at least part of the coding domain of *c-myc*. In each case examined, an ALV provirus was situated at the *c-myc* locus. Physical maps of the interrupted *c-myc* loci from lymphoma DNA were compared with a map of the normal *c-myc* locus generated from restriction endonuclease digests of chicken DNA and from digests of a cloned fragment of chicken DNA containing most or all of the *c-myc* locus (Fig. 1*a*). With these methods, we have identified seven tumours and one cell line with proviruses positioned on the 5′ side of *c-myc* in the same transcriptional orientation (configuration I), one tumour with a provirus on the 3′ side of *c-myc* in the same orientation (configuration II), and four tumours with proviruses on the 5′ side of *c-myc* but in the opposite transcriptional orientation (configuration III). We are unsure of the proviral orientation in the remaining three cell lines, each with multiple proviruses, although there is a provirus upstream from *c-myc* in every case.

We have explored the functional consequences of these arrangements of proviral and *c-myc* DNA by identifying species of polyadenylated RNA from representative tumours with hybridization probes for *myc* and for ALV sequences (particularly U3 and U5, see Fig. 1*c*). In some cases we also determined whether multiple hybridization reagents were annealing with separately co-migrating RNA species or with a single species. Below we present analyses of tumour DNA and RNA from samples illustrating the three arrangements of viral and *c-myc* sequences.

Configuration I: promoter insertion

*Eco*RI digestion of DNA from uninfected chicken cells produces a 14-kilobase pair (kbp) fragment detected by the *Pst*I fragment

0028-0836/82/030209—06$01.00

of cloned MC-29 DNA which served as our *v-myc* probe (referred to hereafter as *myc* probe, see Fig. 1*b* and Fig. 2*b*, lane 2). *myc* probe anneals with two fragments from *Eco*RI digests of DNA from tumour LL4—a new fragment of 3.1 kbp and the normal 14-kbp fragment (Fig. 2*b*, lane 1). The 3.1-kbp fragment was apparently generated by an *Eco*RI site in an ALV LTR adjacent to *c-myc*, as coincident bands were produced by hybridization to either $cDNA_{3'}$ or $cDNA_{5'}$ (Fig. 2*b*, lanes 3, 5). (Fragments of other sizes observed after hybridization of $cDNA_{5'}$ and $cDNA_{3}$, to parallel digests of control DNA (lanes 4, 6) contain sequences from ALV-related endogenous provirus[10,11].) The *Eco*RI site in the ALV LTR is known to be in the U3 domain[4,12]; if the same *Eco*RI restriction fragment anneals to probes for *myc*, U3 and U5, the provirus must be oriented so that it is transcribed in the same direction as *c-myc*. We have previously shown that the single ALV provirus in LL4 is highly defective, composed mostly, if not entirely, of a single LTR; hence, only two new ALV-related *Eco*RI fragments were detected with $cDNA_{3'}$ and only one with $cDNA_{5'}$ (Fig. 2*b*, lanes 3–6). Tests with several additional endonucleases have confirmed the conclusions drawn from the *Eco*RI data and have located the integration site of the defective provirus in LL4 ~0.5 kbp to the left of a *Sac*I site near the 5′ end of the *c-myc* sequences detectable with our *myc* probe (data not shown). Figure 2*a* shows schematically the arrangement of this provirus with respect to *c-myc*.

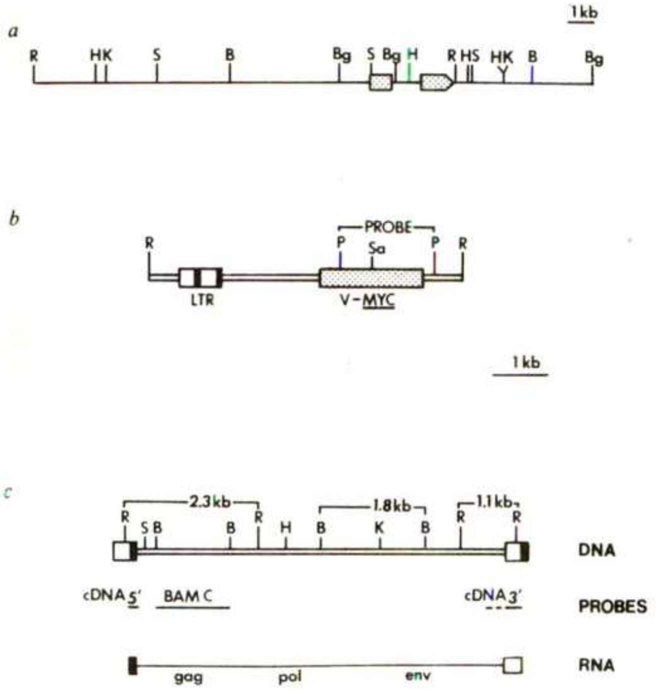

Fig. 1 *a*, Map of restriction endonuclease sites in the region of the chicken genome containing *c-myc*. The physical map of *c-myc* was generated using restriction endonuclease digests of chicken DNA. An identical map has been obtained from a cloned DNA fragment isolated from a recombinant phage library of chicken DNA (B. Vennstrom, manuscript in preparation). The domains homologous to *v-myc* are shown as shaded boxes and were determined using as probe a *Pst*I fragment of cloned MC-29 viral DNA[30], which was subcloned in pBR322. This *Pst*I fragment, as shown schematically in *b*, is 1.5 kbp long and contains, in addition to *v-myc* sequences, a short (<0.3 kbp) sequence from the *env* region of MC-29. As a result, the *v-myc* probe anneals weakly to restriction fragments of ALV-related proviral DNA containing *env* sequences, but the signal is too weak to interfere with our analyses (see Figs 2*b*, 3*b*, 4*b*). The *Pst*I site which marks the 5′ end of the *v-myc* fragment cleaves within the *v-myc* sequences (compare with *b*); thus, a small segment (probably <200 bp) of *v-myc*-specific nucleotides are not represented in the probe, and the shaded boxes may not represent all the *c-myc* coding sequences. The *v-myc* sequences in MC-29 are joined to *gag* sequences encoding viral structure protein[31] generating, on translation, a fusion protein, $P110^{gag\text{-}myc}$ (ref. 32). Thus, the structure of the *c-myc* locus is still incompletely defined, and the map does not indicate transcriptional or translational boundaries for the cellular gene. The direction of transcription of *c-myc* is indicated by the arrow-like shape of the right-hand exon and was determined by preparing restriction fragments from a *Sal*I digest of the *Pst*I *v-myc* fragment as probes specific for the 5′ and 3′ domains of *v-myc*. The length of the intervening sequence was determined by heteroduplex analysis of the cloned *c-myc* DNA fragment and MC-29 viral DNA (B. Vennstrom *et al.* in preparation). (This analysis also confirmed the transcriptional polarity of *c-myc*.) R, *Eco*RI; B, *Bam*HI; S, *Sac*I; K, *Kpn*I; H, *Hin*dIII; Bg, *Bgl*I. *b*, A diagram of cloned MC-29 viral DNA. The MC-29 DNA was cloned by linearizing circular MC-29 viral DNA with *Eco*RI and inserting the DNA into λgtWES · λB (ref. 35). The *Pst*I sites (P) and *Sal* site (Sa) used to generate *v-myc*-specific probes are shown. The *v-myc* region is shown as a shaded box. *c*, Maps of restriction endonuclease sites in RAV-2 DNA. This map was generated as described by Payne *et al.*[4]. The LTRs, ~330 bp, are drawn as boxes at the ends of the DNA. The open box represents sequences specific to the 3′ end of the viral RNA (U3) and the shaded boxes sequences specific to the 5′ end of viral RNA (U5). The approximate location of viral genes are indicated on the diagram of viral RNA. 'Signature fragments', which distinguish RAV-2 DNA from proviruses endogenous to the chickens used in the present study, are marked by lines connecting the two restriction sites. Some of the probes used in our studies represent regions delineated by the labelled lines between the diagrams of viral RNA and DNA. Descriptions of each probe are included in the text and by Payne *et al.*[4].

The configuration of the ALV provirus in LL4 suggests that transcription originating in the proviral LTR could proceed into *c-myc*, in the manner proposed by the promoter insertion model[4,5,7]. The data presented in Fig. 2*c* substantiate this prediction. A single poly(A)$^+$ RNA species of 2.5 kb was detected with $cDNA_{5'}$ (Fig. 2*c*, lane 7). No other species of RNA were observed with probes for other regions of the viral genome, including U3 (Fig. 2*c*, lane 8), a result compatible with the truncated structure of the LL4 provirus. The *myc* probe also anneals to a 2.5-kb species of RNA from LL4 (Fig. 2*c*, lane 9), suggesting that the transcripts observed with $cDNA_{5'}$ also carry *myc* sequences. Uninfected chick embryo fibroblasts also contain 2.5-kb transcripts which anneal with *myc* probe and presumably represent the normal transcription products of *c-myc*[13] (Fig. 2*c*, lane 10); *c-myc* RNA of the same size and

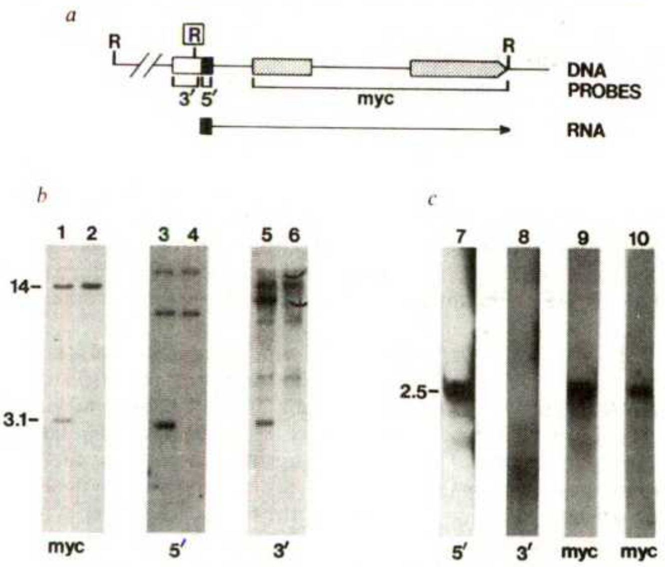

Fig. 2 Configuration I: ALV and *c-myc* DNA and RNA in tumour LL4. *a*, Diagram of the structure of the single ALV provirus in tumour LL4[4] and its position and transcriptional orientation relative to *c-myc*. The symbols for the proviral LTR and *c-myc* DNA are as described in Fig. 1 legend. Cell DNA is represented as a single line. The proviral *Eco*RI site responsible for the 3.1-kbp fragment detected in *b* is enclosed in a box. The sequences detected by the probes used in *b* and *c* are delineated under the diagram of the DNA. The virus-specific RNA in this tumour is shown schematically below the probes. (As these transcripts are equivalent in size to normal *c-myc* transcripts, we presume the hybrid RNA is processed but we are unsure of its precise composition.) *b*, 5 µg each of LL4 tumour (odd-numbered lanes) and DNA from uninfected tissue (even-numbered lanes) from the same bird were digested with *Eco*RI, electrophoresed through 0.8% agarose, transferred to nitrocellulose and annealed sequentially to the probes indicated beneath the lanes[4]. Sizes in kilobases are shown beside the lanes. *c*, Lanes 7–9, poly(A)$^+$ RNA was prepared from the tumour as described by Varmus *et al.*[17] except that frozen tissue was homogenized using a tissumizer (Tekmar) and 20-µg samples were electrophoresed through 1.2% methyl mercury agarose, transferred to diazobenzylmethoxy(DBM)-cellulose paper[33] and annealed sequentially to the designated probes[34]. Lane 10, 50 µg poly(A)$^+$ RNA from uninfected chick embryo fibroblasts was prepared and analysed as described above. The autoradiogram of lane 10 was exposed 8.7 times as long as the autoradiogram of lane 9.

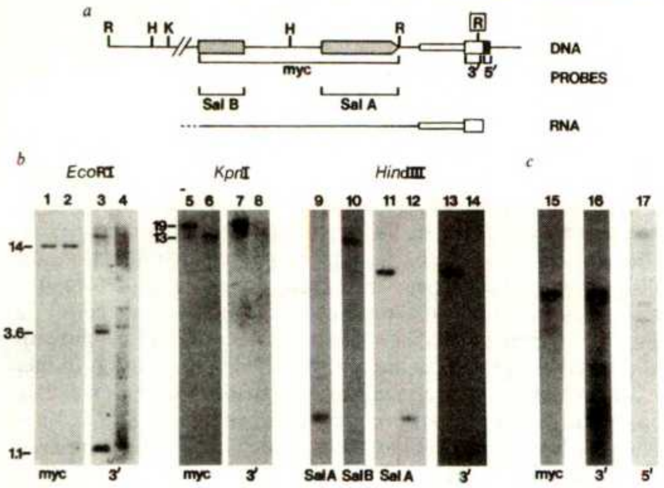

Fig. 3 Configuration II: ALV and *c-myc* DNA and RNA in tumour LL6. *a*, Diagram of the provirus and *c-myc* and the resulting transcripts in LL6 as revealed using the indicated probes in analyses shown in *b* and *c*. The symbols and the preparation of the *Sal* A and *Sal* B probes are described in Fig. 1 legend. Proviral DNA is represented as two parallel lines, cell DNA as one line. The *Eco*RI site introduced by the provirus is boxed. As explained in the text, a large deletion of cellular DNA has occurred on the 3' side of *c-myc* but the precise position and size of the deleted DNA are unknown. The *Hin*dIII, *Kpn*I and *Eco*RI sites on the right-hand side of the provirus lie beyond the region depicted and have been omitted here. *b*, Lanes 1–8, 11–14, tumour DNA (odd-numbered lanes) and uninfected DNA (even-numbered lanes) were analysed with *Eco*RI, *Kpn*I and *Hin*dIII using methods described in the legend to Fig. 2*b*. Lanes 9, 10, uninfected chicken embryo DNA analysed as for Fig. 2*b*. *c*, tumour RNA was analysed as for Fig. 2*c*.

abundance is present in normal bursal tissue (D. Sheiness and T. Gonda, personal communication). The concentration of *c-myc* RNA in LL4 was $\sim$70-fold greater than in normal tissues as determined by densitometry, with adjustments for the amounts of RNA and the autoradiographic exposure times for lanes 9 and 10 (see Fig. 2 legend). Although the transcripts revealed in lanes 9 and 10 are similar in size, we do not know the precise composition of the stable species. It is likely that the transcripts in tumour LL4 have been initiated at a novel promoter provided by the ALV LTR, elongated through the *c-myc* locus and processed to remove at least some intervening sequences.

Configuration II: proviral insertion downstream from *c-myc*

*Eco*RI digests of DNA from tumour LL6 do not contain a novel *c-myc* fragment (Fig. 3*b*, lanes 1, 2). Hybridization with cDNA$_{3'}$ (Fig. 3*b*, lanes 3, 4) confirmed that *c-myc* and ALV proviral sequences are not present in the same *Eco*RI restriction fragment. However, *Kpn*I digestion of tumour DNA produced a new *myc*-specific fragment of $\sim$19 kbp in addition to the normal *c-myc* 13-kbp fragment (Fig. 3*b*, lanes 5, 6). The relative intensity of the bands representing the two *Kpn*I fragments implies that the uninterrupted *c-myc* allele is less abundant than the normal locus. This finding has been confirmed with other enzymes (see, for example, the analysis with *Hin*dIII in lane 11) and observed with several other tumours in our collection; we presume that the tumour cells in these cases are aneuploid for the chromosome bearing *c-myc*.

The annealing of cDNA$_{3'}$ to the 19-kbp *Kpn*I fragment (Fig. 3*b*, lane 7) provides evidence for an ALV provirus between the *Eco*RI site at the 3' end of *c-myc* and a *Kpn*I site positioned further to the right. Confirmatory data for an insertion on the 3' side of *c-myc* were derived from *Bam*HI, *Bgl*I, and *Hin*dIII digests (not shown). Further support was obtained using *Sal*I–*Pst*I fragments of *v-myc* as probes to distinguish between the 5' and 3' exons of *c-myc*. When uninfected chicken DNA is digested with an enzyme (for example, *Hin*dIII) which cleaves within the only identified *c-myc* intron (B. Vennstrom *et al.*, manuscript in preparation), the *Sal* A probe (from the 3' end of *v-myc*) detects a 1.8-kbp *Hin*dIII fragment in digests of normal chicken DNA, whereas the *Sal* B probe (from the 5' end of *v-myc*) detects a 10-kbp *Hin*dIII fragment (Fig. 3*b*, lanes 9, 10). Using the *Sal* A probe to analyse digests of LL6 DNA, we identified a new *Hin*dIII fragment (6.6 kb) that also contains ALV sequences (Fig. 3*b*, lanes 11–14), confirming the position of the ALV provirus near the 3' end of *c-myc*. Further data (not presented here) show that the ALV provirus in LL6 has incurred a large deletion, leaving only the 3' LTR and $\sim$0.7 kb of adjacent viral DNA. Furthermore, a large deletion spanning at least 15 kb of cellular DNA on the 3' side of *c-myc* has occurred in this tumour, removing the *Hin*dIII, *Kpn*I and *Sac*I sites normally proximal to the 3' exon of *c-myc* (compare with Fig. 1*a*). (This deletion explains why the apparent increments in size of *Kpn*I and *Hin*dIII fragments in LL6 greatly exceed the size of the proviral insert.) Additional mapping results (not shown) place the defective provirus within 500 bp of the *Eco*RI site on the 3' side of the *v-myc*-related sequences in the same transcriptional orientation (Fig. 3*a*).

LL6 contains polyadenylated RNA of 3.7 kb which anneals to *myc* probe and cDNA$_{3'}$ but not to cDNA$_{5'}$ (Fig. 3*c*, lanes 15–17). The increase in transcript size over the size of normal *c-myc* transcripts may be partly due to ALV sequences; a probe homologous to the 3' end of *env* also hybridizes to the 3.7-kb transcripts (not shown). The concentration of this RNA was estimated to be 20 times greater than that of *c-myc* RNA in normal bursa or fibroblasts. The arrangement of the template and the size and content of the RNA suggest that transcription of *c-myc* in LL6 originates upstream from *c-myc*, perhaps at the normal initiation site, and proceeds into the ALV provirus, with termination or polyadenylation occurring in or near the end of U3 (see Fig. 3*a*). The ALV provirus has therefore altered the normal biogenesis of *c-myc* RNA, probably by replacing the *c-myc* sequences normally recognized as signals for transcript termination or polyadenylation.

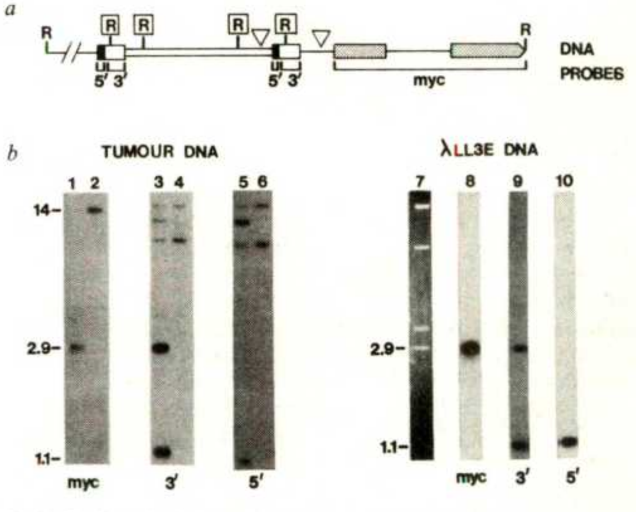

Fig. 4 Configuration III: ALV and *c-myc* DNA in tumour LL3. *a*, Diagram of the ALV provirus and *c-myc* in tumour LL3; the triangles represent deletions. The provirus in the primary tumour LL7 and its liver metastasis have a similar configuration to those in LL3 except there is no deletion in the cell DNA and the deletion within the ALV provirus is smaller. *b*, Lanes 1–6 represent analysis of *Eco*RI digests of tumour DNA (odd-numbered lanes) and uninfected tissue DNA (even-numbered lanes) using probes for *myc*, U3 and U5 as described in the legends to previous figures. Lanes 7–10 contain DNA from λLL3E, a recombinant bacteriophage carrying *c-myc* and part of the ALV provirus from LL3 tumour DNA. Lane 7, a photograph of the ethidium bromide-stained *Eco*RI digest of λLL3E DNA visualized by transillumination with UV light; lanes 8–10, autoradiograms of the results of sequential hybridizations with *myc* probe, cDNA$_{3'}$ and cDNA$_{5'}$ to cloned DNA transferred to nitrocellulose. λLL3E and two others containing different DNA fragments from the *c-myc* region of LL3 tumour DNA were isolated from a recombinant DNA library of partial products of *Sau*3A digestion of tumour DNA cloned in the bacteriophage vector λ1059[14]. Size-fractionated DNA, $\sim$20 kb long, was selected by preparative electrophoresis of 200 μg of digested DNA through low-melting agarose (Seaplaque)[4]. After recombinant molecules had been packaged *in vitro*[35] and used to infect *Escherichia coli* Q359[14], recombinant phage carrying the ALV provirus were detected using cDNA$_{3'}$ (ref. 36).

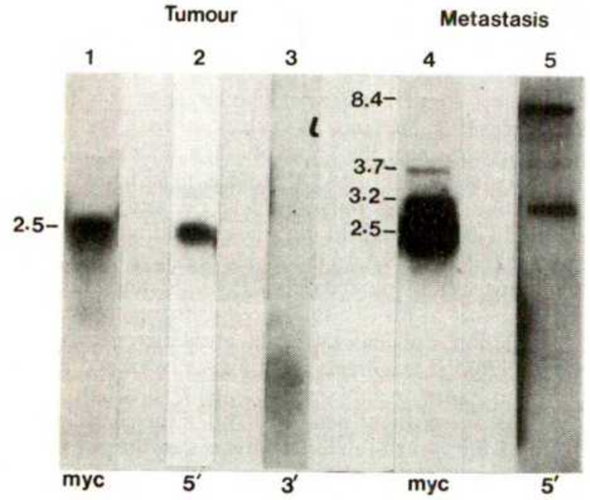

Fig. 5 Configuration III; ALV and *c-myc* RNA in tumour LL7 and its metastasis. Lanes 1–3, analysis of virus-specific RNA from bursal tumour LL7 was performed as in Fig. 2*c*. Lanes 4 and 5 represent an analysis of RNA from a liver metastasis from tumour LL7. 5 μg of poly(A)$^+$ RNA was electrophoresed through 1.2% formaldehyde agarose and transferred to nitrocellulose[37]. The sequential hybridizations using the indicated probes were performed as with the DBM-filter bound RNA.

Configuration III: proviral insertion upstream from *c-myc* in the 'opposite' orientation

Hybridization of *Eco*RI-digested LL3 DNA with *myc* probe reveals a 2.9-kbp fragment in addition to the normal 14-kbp fragment (Fig. 4*b*, lanes 1, 2). Unlike the new *Eco*RI fragment seen in digests of LL4 DNA (see Fig. 2*b*), the 2.9-kbp fragment from LL3 DNA anneals with cDNA$_{3'}$ but not cDNA$_{5'}$ (Fig. 4*b*, lanes 3–6). The most likely interpretation of these data (Fig. 4*a*) is that the LTR adjacent to *c-myc* has assumed a transcriptional orientation opposite to that of *c-myc*. Digestion of LL3 tumour DNA with *Kpn*I and *Hin*dIII followed by sequential annealings with *Bam* C probe and *myc* probe confirmed the proposed orientation (data not shown). Our conclusion is further supported by previously reported evidence that the ALV proviruses in LL3 and LL4 are in opposite orientations within the same chromosomal context[4].

We have constructed a recombinant DNA library of LL3 DNA by inserting tumour DNA partially digested with *Sau*3A into the bacteriophage vector λ1059 (ref. 14). Three recombinant phage containing the ALV provirus and flanking cell sequences were isolated from the library. Figure 4*c* shows ethidium bromide-stained, *Eco*RI-digested DNA from one of our isolates (lane 7) and the results after Southern transfer and hybridization with *myc* probe, cDNA$_{3'}$ and cDNA$_{5'}$ (lanes 8–10). The 2.9-kbp fragment derived from the cloned DNA anneals to cDNA$_{3'}$ and *myc* probe but not to cDNA$_{5'}$. These data and a more detailed analysis of our three isolates (not shown) are in complete agreement with the results obtained using tumour DNA.

Three other bursal tumours (LL2 (ref. 4), LL5 and LL7) have an arrangement of ALV DNA and *c-myc* similar to that described for LL3. We previously reported that LL2 and LL3 lack polyadenylated RNA detectable with cDNA$_{\mathrm{rep}}$ or cDNA$_{5'}$. These results, together with the conclusions from restriction mapping, imply that if the *c-myc* locus is activated by the adjacent ALV DNA in these tumours, a viral promoter is not directly responsible. To address this issue with reagents specific for *c-myc* as well as ALV sequences, we examined RNA from the primary tumour and a large hepatic metastasis of LL7. *myc* probe reveals a species of RNA in the LL7 bursal tumour migrating at 2.5 kb (Fig. 5, lane 1). Surprisingly, this RNA also seemed to react with cDNA$_{5'}$ (Fig. 5, lane 2) but not with probes for other regions of the genome, including cDNA$_{3'}$ (Fig. 5, lane 3). Because our cDNA$_{5'}$ probe is strand specific (it only detects RNA with the same polarity as the viral RNA genome), the orientation of the ALV provirus and *c-myc* in tumour LL7 precludes the possibility that ALV U5 sequences from this provirus are physically joined to a transcript of the *c-myc* coding strand (see Fig. 4*a*). This type of transcript might be produced by a subset of cells in LL7 containing a provirus upstream from *c-myc* in the same orientation. These cells could produce high levels of transcripts with U5 sequences joined to *c-myc* sequences and remain undetected in our DNA analyses if they represented <10% of the total tumour cell population.

In an attempt to isolate a homogeneous population of tumour cells, we examined a liver metastasis from the LL7 tumour. Metastases are often clonal expansions of single tumour cells[4,15]; restriction enzyme analyses of the metastasis DNA (not shown) indicated that the arrangement of ALV and *c-myc* DNA in the LL7 metastasis was identical to that in the predominant cell population in the primary tumour. However, the major 2.5-kb species of RNA from the metastasis which annealed to the *myc* probe did not react with cDNA$_{5'}$ (Fig. 5, lane 5) or anneal to probes for other regions of the ALV genome (data not shown).

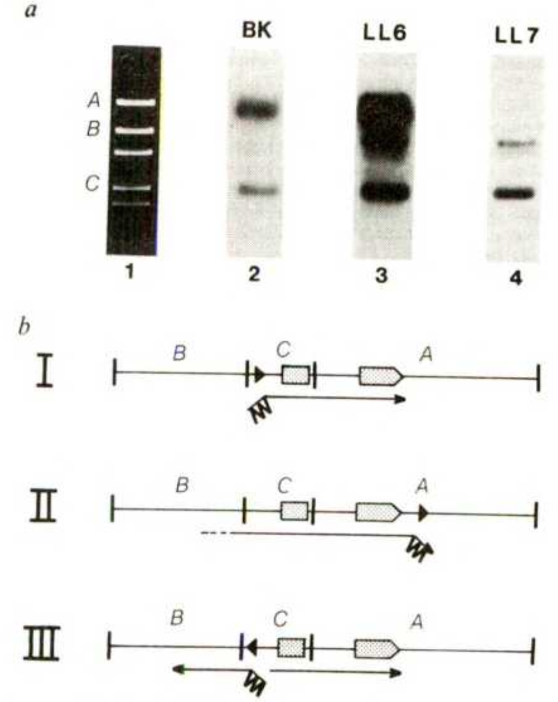

Fig. 6 Tests for linkage of ALV and *myc* sequences in tumour RNAs. The sandwich blot procedure of Dunn and Hassell[16], modified as described below, was used to assess physical linkage of ALV sequences and *myc* sequences in RNA prepared from BK 4484A cell line RNA (lane 2), LL6 RNA (lane 3) and LL7 liver metastasis RNA (lane 4). The 10-kbp *Bam*HI fragment containing *c-myc* (see Fig. 1*a*), obtained from a digest of the recombinant DNA described in Fig. 1*a* legend, was subcloned into pBR322 (D. Sheiness, unpublished). 1 μg of this plasmid, pCMC-2, was digested with *Bam*HI and *Bgl*I and electrophoresed through 1.2% agarose. The DNA was detected as described in Fig. 4 legend, then transferred to nitrocellulose. 5 μg of poly-(A)$^+$ RNA was resuspended in 200 μl of an annealing mix consisting of 50% formamide, 0.5 M NaCl, 20 mM PIPES *p*H 6.8, 5 mM Na$_2$EDTA, 0.4% SDS, 250 μg ml^{-1} poly(A), 2 × Denhardt's solution[38], 200 μg ml^{-1} carrier yeast RNA. This solution was applied to the filter-bound DNA and incubated for 24 h at 41 °C. The filter was washed twice at 53 °C for 15 min, each with 0.1 × SSC, 0.1% SDS. The filter was blotted dry and annealed to cDNA$_{5'}$ or cDNA$_{3'}$ as described by Quintrell *et al.*[34]. This filter was washed twice for 1 h each time at 37 °C with 0.1 × SSC, 0.1% SDS, dried and autoradiographed. Lane 1, photograph of ethidium bromide-stained *Bgl*I–*Bam*HI digest of pCMC-2 DNA. The bands labelled *A*, *B* and *C* result from the *c-myc* insert and are shown schematically in *b*. The other bands consist of pBR322 DNA sequences. Lanes 2, 4, filters annealed to cDNA$_{5'}$. Lane 3, filter annealed to cDNA$_{3'}$. *b*, Diagrams of transcriptional patterns in configurations I, II and III based on sandwich blots shown in *a* and analyses of tumour RNA from BK cell line (not shown), LL6 (Fig. 3*c*) and LL7 (Fig. 5, lanes 4, 5). The restriction sites are labelled as in Fig. 1*a* and the fragments designated *A*, *B* and *C* in *a* are shown. The arrowhead marks the position of the ALV provirus and indicates its transcriptional orientation. The transcriptional pattern of each configuration is shown as an arrow below the diagram. The inclined tail of an arrow marked with a serrated line indicates ALV U5 sequences detected with cDNA$_{5'}$ in configurations I and III, and ALV U3 sequences detected with cDNA$_{3'}$ in configuration II.

Thus, the metastatic process seemed to isolate a population of tumour cells with an ALV provirus upstream from *c-myc* in the opposite orientation and with enhanced expression of *c-myc* in the absence of a fused transcript. The analysis of metastasis RNA in Fig. 5 revealed minor transcripts (3.7 and 3.2 kb in lane 4; 8.4 and 3.2 kb in lane 5) which were apparently absent from the primary tumour. However, long autoradiographic exposures of the filters carrying primary tumour RNA revealed faint bands corresponding to these species (not shown). The 8.4- and 3.2-kb transcripts revealed by cDNA$_{5'}$ represent normal ALV mRNAs and imply the presence of a few cells which harbour non-defective ALV proviruses, either superinfected metastatic lymphocytes or infected normal liver cells. The coincidence of the 3.2-kb transcript detected by the probes in Fig. 5, lanes 4 and 5, can be attributed to co-migrating transcripts (see below).

The *myc* and ALV sequences are covalently joined in RNA from tumours with configurations I and II but not III

Using the 'sandwich blot' procedure of Dunn and Hassell[16] (Fig. 6), we assessed whether ALV U5 sequences were physically linked to *myc* sequences in tumour transcripts. *Bam*HI–*Bgl*I double digests of cloned chicken *c-myc* DNA were electrophoresed (Fig. 6*a*, lane 1) and transferred to nitrocellulose. Unlabelled tumour RNA was annealed to the filter-bound DNA, the filters were washed, and RNA containing ALV U5 or U3 sequences detected by hybridization to labelled cDNA$_{5'}$ or cDNA$_{3'}$. An autoradiographic signal in a position corresponding to one of the *Bam*HI–*Bgl*I restriction fragments indicates physical linkage in RNA of sequences homologous to both the restriction fragment and the ALV LTR. When we used RNA from a tumour cell line (BK 4484A) containing an ALV provirus upstream from *c-myc* in a parallel orientation (configuration I), we observed bands corresponding to fragments *A* and *C* but not *B* when cDNA$_{5'}$ was used as a radioactive probe (Fig. 6*a*, lane 2). This result proves that these cells contain transcripts consisting of ALV U5 sequences physically linked to the *c-myc* sequences in fragments *C* and *A*. This conclusion is shown schematically in configuration I of Fig. 6*b* and conforms to the promoter insertion model.

Figure 6*a*, lane 3, demonstrates that ALV U3 sequences and *myc* sequences are physically linked in RNA from tumour LL6. The signal observed with cDNA$_{3'}$ at the position of fragment *B* locates the 5′ end of these transcripts at least 1 kb upstream from the *Sac*I site marking the 5′ end of the *c-myc* sequences detected by our probe (see Figs 1*a*, 6*b*). If these transcripts originate at the normal *c-myc* promoter, these data place that promoter to the left of the *Bgl*I site which defines the right end of fragment *B* (see configuration II in Fig. 6*b*). Studies of three tumours (LL4, LL5 and LL7) and one cell line (BK 4484A) showed that each provirus is integrated to the right of this *Bgl*I site. Thus, proviruses integrated 5′ to *c-myc* in configurations I and III (see below) would be positioned between the normal promoter and the *myc* sequences that we have detected at increased concentrations in tumour RNA; this could mean that a secondary initiation site is used for *myc* RNA in these cases. We cannot, however, exclude other possibilities; for example, the transcripts in tumour LL6 may be initiated aberrantly, thus obscuring the location of the true *c-myc* promoter, or viral sequences could be transcribed in configuration III and removed from RNA by splicing.

RNA from the LL7 metastasis contains transcripts with U5 joined to sequences in fragments *C* and *B* but not *A* (Fig. 6*a*, lane 4). Because restriction mapping data (not shown) place the ALV provirus in LL7 5′ to the *c-myc* sequences detected by our probe, the sandwich blot indicates that transcription probably originates in the proviral LTR and proceeds through the region represented in fragment *C* and into that contained in fragment *B*. It also confirms that ALV U5 sequences are not joined to the identified *c-myc* coding sequences in transcripts (Fig. 5). Thus, the 3.2-kb RNA species revealed in Fig. 5, lanes 4 and 5, probably represents co-migration of *env* mRNA and a minor *c-myc* transcript containing no ALV sequences.

The ALV provirus can act as an insertional mutagen

We have assessed the relative configurations of ALV proviruses and *c-myc* in 12 ALV-induced bursal lymphomas and 4 cell lines derived from ALV-induced tumours. Each tumour or cell line harboured an ALV provirus situated in the region of *c-myc*, and, in every case examined (five tumours and four cell lines), this insertion was associated with levels of *myc*-containing transcripts elevated 20–100-fold over levels of *c-myc* transcripts in uninfected bursa. These data further support the proposal[7] that ALV exerts its oncogenic effects by increasing the expression of *c-myc*.

Based on the structures of *c-myc* DNA and RNA in their tumours, Hayward *et al.*[7] have argued that the increased level of *c-myc* transcription is uniformly due to the insertion of an ALV promoter upstream from the gene, thus subverting the expression of *c-myc* by supplying a promoter more efficient than its own. In contrast, we have shown that ALV proviruses can assume three different configurations with respect to *c-myc*, and that each configuration is associated with increased transcription of *c-myc*. We have been unable to identify a significant divergence in experimental protocol that might explain the differences between our results and those of Hayward *et al.* In view of our results, we propose that the ALV provirus (specifically the LTR) can act as an insertional mutagen capable of enhancing the expression of a cellular gene, *c-myc*, by as yet unknown mechanisms, one aspect of which may be reflected in promoter insertion.

The belief that these phenomena are instrumental in lymphomagenesis is founded primarily on the extraordinary frequency with which proviral insertions in the *c-myc* locus and high levels of *c-myc* RNA are encountered in ALV-induced bursal tumours. However, the techniques used thus far have not identified the stage of tumour induction at which *c-myc* is affected, nor have they fully assessed the possibility that sequential rearrangements have occurred at the proviral integration sites within the *c-myc* locus. (In fact, deletions affecting proviral or flanking cellular sequences have been encountered at a much greater frequency in this experimental context[4–6] than in others (see ref. 17).) In addition, transformation experiments with DNA from bursal lymphomas indicate that oncogenic loci devoid of viral or *c-myc* sequences may also be activated during the neoplastic process[18,19].

The transcriptional enhancement exerted by the ALV provirus during leukaemogenesis constitutes one of two possible mutagenic effects on the host genome following retroviral DNA insertion: proviruses can also inactivate host genes. The abolition of *v-src* expression due to the insertion of Moloney murine leukaemia virus (Mo-MLV) DNA into a Rous sarcoma virus provirus has recently been observed in culture[17]. Also, the mouse genotype *dilute* may be due to an endogenous MLV provirus inserted at a coat colour-determining locus[20]. The mutagenic properties of retroviral proviruses, as well as structural features[21], are shared with transposable elements found in bacteria and yeast. Although transposable elements have usually been reported to inactivate genes when they induce mutations[22], this probably reflects the genetic selection used; IS*2* in bacteria[23] and Ty*1* in yeast[24,25] also alter the expression of adjacent genes in a positive manner by mechanisms still incompletely defined.

The mechanism of transcriptional enhancement

The mechanism of ALV-induced enhancement of *c-myc* expression also remains obscure. However, two general, non-exclusive proposals can be considered. First, the increase of *c-myc* expression in each of the three observed configurations may reflect properties of *c-myc*. *c-myc* could be under the control of *cis*-acting regulatory elements either 5′ or 3′ to the gene. Integration of ALV DNA into these sequences could then release *c-myc* from their influence. Experiments of Cooper *et al.*[26] suggest that *cis*-acting sequences regulate expression of endogenous chicken proviruses, and *cis*-acting regulators on the 3′ side of a gene have been reported for the mating type locus in yeast[27] and the fetal globin genes in humans[28]. A second, more likely proposal postulates that enhancement reflects a distinctive property of the provirus rather than a property of *c-myc*. For example, the provirus could increase the accessibility of *c-myc* to the host cell's transcriptional machinery by altering the nucleosome positions in the region of *c-myc*. This could account for increased *c-myc* expression in each configuration. Alternatively, the mechanism of enhancement could be unique for each configuration. The proviral LTR could act as a *c-myc* promoter if inserted in the correct orientation upstream from *c-myc*. If inserted in the proper orientation downstream from *c-myc*, the provirus could act to stabilize the *c-myc* transcripts. If inserted upstream from *c-myc* but in an opposite orientation, it could affect chromatin structure or bind accessory transcriptional factors in ways which might increase transcription in both directions.

The hypothesis that a retroviral LTR can enhance the expression of a linked gene may find support in experiments which introduce selectable genes into cultured cells either as a calcium phosphate precipitate or by microinjection. The Moloney murine sarcoma virus LTR markedly augments the frequency of morphological transformation of NIH-3T3 cells by a restriction fragment containing the putative transforming gene of murine sarcoma virus (*v-mos*). This augmentation occurs when the LTR is positioned on either the 5′ or 3′ side of the viral oncogene[29]. When the LTR has been positioned downstream from *v-mos* with the same transcriptional polarity, transcripts which proceed through *v-mos* and terminate in the U3 region are observed in the transformed cells (T. Wood and G. Vande Woude, personal communication). This situation is analogous to the transcriptional pattern found in tumour LL6. Placement of the Rous sarcoma virus LTR at either the 5′ or 3′ end of a complete herpes simplex virus thymidine kinase (HSV-*tk*) gene, including the true HSV-*tk* promoter, enhances the number of HSV-*tk*-positive colonies after microinjection into tk^- mouse L cells (P. Luciw and M. Capecchi, personal communication). It is unclear whether the effect of the retroviral LTR in these cell culture experiments is to increase transcription of the adjacent genes.

In conclusion, we have proposed that the ALV provirus contains a previously unknown ability, independent of its configuration, to affect the transcriptional activity of adjacent cellular DNA. The transcriptional enhancement provided by the ALV provirus suggests that novel mechanisms may control the expression of eukaryotic genes.

We thank Bjorn Vennstrom, Diana Sheiness and Ron Swanstrom for provision of cloned DNA, Lyman Crittenden for supervising the induction of the tumours, W. Hayward for communicating results before publication, S. Courtneidge and H. Hihara for providing the tumour cell lines, J. Migneault for typing the manuscript, and our colleagues, particularly Steve Hughes, Ron Swanstrom, Richard Parker and John Majors, for advice and discussion. This work was supported by grants from the American Cancer Society and the NIH; G.P. is supported by an NIH training grant.

Occurrence of the 3.3-μm feature in galaxies

T. J. Lee*, D. H. Beattie*, Ian Gatley*,
P. W. J. L. Brand†, T. Jones‡ & A. R. Hyland‡

* UK Infrared Telescope, 900 Leilani Street, Hilo, Hawaii 96720, USA
† Department of Astronomy, University of Edinburgh, Edinburgh EH9 3HJ, UK
‡ Australian National University, Canberra ACT, Australia

Many emission features have been discovered, in dusty ionized regions such as planetary nebulae or H II regions, with wavelengths longer than 2 μm (ref. 1). Some are gaseous emission lines but many that are too broad to be due to single atoms are attributed to emission from dust grains in or near the ionized gas. The feature at 3.28 μm ('the 3.3-μm feature') has been observed in H II regions[2,3] in planetary nebulae[4] and in particular, in the following extragalactic objects: 3C273 (ref. 5) (quasar), NGC4151 (ref. 6), M82 (ref. 7), NGC253 (ref. 8), NGC2903 (ref. 9), NGC5195 (ref. 9) and NGC6946 (ref. 9). We report here new measurements which contradict some of these results. In particular, we find the feature in the late-type galaxy M83 but do not observe it in either the Seyfert galaxy NGC4151 or the quasar 3C273.

The mechanism that produces the line is thought to be due either to fluorescence of the grains in a UV radiation field[10] (but this requires very high efficiencies) or to the heating of very small grains to high temperatures (several hundred degrees)[11]. The presence of the feature in extragalactic objects such as late-type galaxies is not surprising because these objects contain many H II regions. Measures of equivalent width of the feature will indicate the chemical composition, once studies of galactic objects have established the exact nature of the mechanism. In objects such as Seyfert galaxies and quasars, however, the presence or absence of the 3.3μm feature is important as it is one

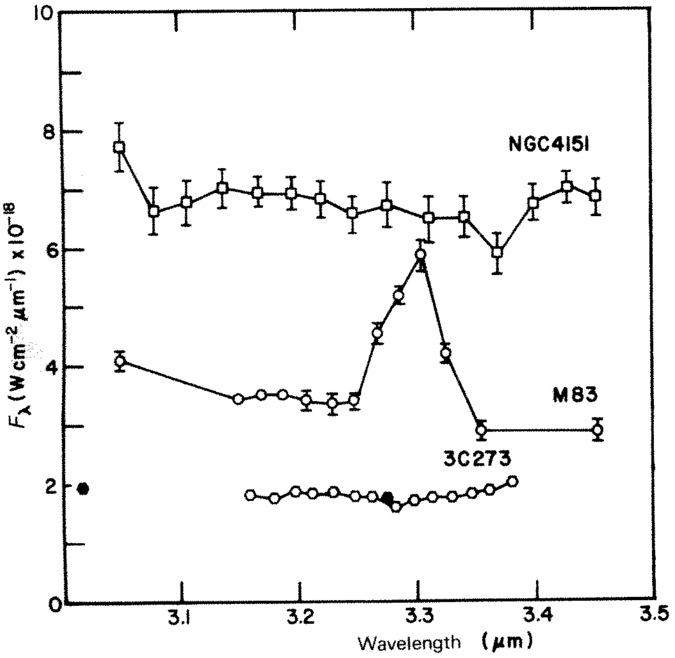

Fig. 1 The circular variable filter spectra of the three objects: NGC4151, M83 and 3C273. The wavelengths are rest wavelengths and broad-band filter measurements are also plotted for the quasar 3C273 as solid symbols. The error bars are ±1 s.d.

of the few unambiguous dust indicators available to settle the question of the presence of dust grains in the nuclei of active galaxies.

As part of a programme to observe a larger number of objects, we have measured the spectra of 3C273, M83 and NGC4151 in the region of the local rest wavelength of the 3.3-μm feature. This was carried out on the nights of 21, 22 and 23 May (UT) 1981, one object being measured each night. In addition, NGC4151 had been observed on 12 April 1981. During these nights the sky was clear above Mauna Kea summit and the visibility good. The telescope and instrumentation used were the UK Infrared Telescope (3.8 m) with an InSb CVF spectrophotometer (1% resolution). Apertures and chopper throws respectively were 7.3 and 13 arc s for 3C273, 10.8 and 18 arc s for M83, and 14.4 and 18 arc s for NGC4151. The wavelengths at which measurements were taken were spaced at 0.02-μm intervals near to the position of the feature and a few more widely spaced points were also measured. In addition broadband data were obtained. At each observed point several 10-s integrations were made and total integration times were 5,600 s for 3C273,4,820 s for M83 and 5,640 s for NGC4151. The spectra are shown in Fig. 1, where the flux density F_λ is plotted against the rest wavelength. For both 3C273 and M83 two spectra were averaged, while for NGC4151 the April data are shown.

The April data on NGC4151 are the more extensive in wavelength and of better signal-to-noise ratio. These data set a 3σ upper limit of 8% of continuum on line height above the continuum (while the May data set a poorer upper limit of 23%). For 3C273, the corresponding limit is 9% of continuum. These limits are conservative, being based on the assumption of a flat baseline, and the spectral profile of the CVF. If the continuum outside the region of the line were to be slightly curved this would reduce the upper limits by a factor of ~2. These limits should be compared with previously[5,6] suggested values of 30% and 40% respectively. Although both 3C273 and NGC4151 are variable by a few tens of per cent, our continuum levels are sufficiently close to, and also fainter than, the previously measured continuum levels, and this cannot cause such a discrepancy.

In M83, a late-type galaxy with H II regions in its nuclear region[12], the 3.3-μm feature is clearly seen in Fig. 1. Equally clearly, at the levels discussed above, the feature is not present in either the Seyfert galaxy NGC4151 or the quasar 3C273. The excellent transparency in the 3-μm region at the summit of Mauna Kea and high instrumental instantaneous signal-to-noise ratios mean that previous detection of the 3.3-μm feature must be considered suspect. This experiment shows no evidence for dust in the Seyfert galaxy NGC4151 or the quasar 3C273, but clearly demonstrates that the dust in M83 and in H II regions in our Galaxy share similar properties.

γ-Quanta capture by magnetic field and pair creation suppression in pulsars

A. E. Shabad

P. N. Lebedev Physical Institute, Leninskiy prospect 53,
Moscow, USSR

V. V. Usov

Space Research Institute, Profsoyusnaya 88, Moscow, USSR

The theory[1] that electron–positron pairs in magnetospheres of pulsars are created by the interaction of γ-quanta with the magnetic field B is the basis of the modern theory of pulsars[2,3]. When considering the process $\gamma + B \rightarrow e^+ + e^- + B$ in pulsars it is usually accepted that the γ-quanta produced by the curvature irradiation of the primary particles are emitted tangentially to the curved line of force of magnetic field and propagate directly. As they do so the pitch angle between the photon wave vector K and the magnetic field B increases until a certain value ψ_1 when the absorption of the photon through pair creation becomes possible. We emphasize here that if the resonant behaviour characteristic of the vacuum polarization in a magnetic field[4,5] is considered this picture changes considerably. Namely, the trajectories of γ-quanta are strongly bent towards the direction of the magnetic field if the latter is sufficiently intense and at the same time the creation is suppressed. We also discuss the effect this may have on the energy yield of pulsars.

In a medium possessing a space-non-uniform refraction index, to which a strong magnetic field with curved lines of force in a vacuum is an example, a photon must propagate along a curved path. However, in this case the path would be curved negligibly as long as the traditional expression[6] for the refraction index is used which differs from unity only by $\sim 10^{-5}$ (for the fields $B \sim 10^{12}$ G). The expressions given in ref. 6, as well as those in later publications, however, do not cover the resonant situation which occurs in the vicinity of the pair creation threshold. This resonant situation has been examined[4,5] on the basis of the first off-mass-shell calculation of the polarization operator in an external magnetic (with electric, as well) field outlined in ref. 7 for arbitrarily strong fields. It was found that the dispersion curve deflects from its conventional shape $\omega/c = |\mathbf{K}|$ which survives only in the region far away from the resonance (ω is the frequency). The resonant dependence of the component $K_\parallel$ of the photon wave vector parallel to the

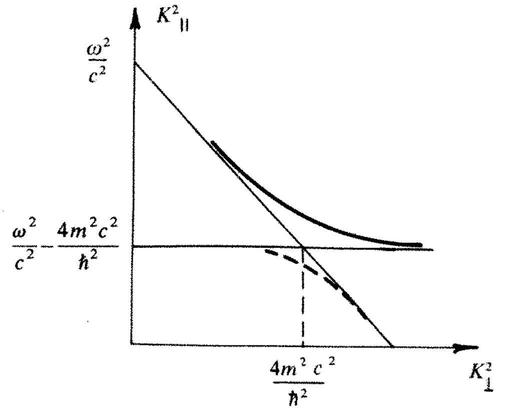

Fig. 1 Two disconnected branches of the dispersion curve of the photon in a magnetic field.

magnetic field **B** on its component $K_\perp$ across **B** with ω kept fixed is shown in Fig. 1. Part of the dispersion curve near the first threshold

$$(K^2_\parallel)_{\text{thr}}=\frac{\omega^2}{c^2}-\frac{4m^2c^2}{\hbar^2} \tag{1}$$

is shown as the solid line in Fig. 1. For $K^2_\parallel \leqslant (K^2_\parallel)_{\text{thr}}$ electrons and positrons are virtually created. Other thresholds, if the value of ω is large enough, are located between the lines $K^2_\parallel = (K^2_\parallel)_{\text{thr}}$ and $K^2_\parallel = 0$. The solid dispersion curve near the threshold is given by the relation

$$K^2_\parallel=\frac{\omega^2}{c^2}+f(K^2_\perp) \tag{2}$$

where

$$f(K^2_\perp)=-\frac{4m^2c^2}{\hbar^2}-\frac{2}{3}\left(K^2_\perp-\frac{4m^2c^2}{\hbar^2}\right)+[((\phi^2+g^3)^{1/2}+\phi)^{2/3}+((\phi^2+g^3)^{1/2}-\phi)^{2/3}]\frac{m^2c^2}{\hbar^2} \tag{3}$$

Here

$$g=\frac{1}{3}\left(\frac{\hbar^2K^2_\perp}{m^2c^2}-4\right), \qquad \phi=\alpha\frac{B}{B_{\text{cr}}}\exp\left(-\frac{K^2_\perp c\hbar}{2eB}\right)$$

where

$$\alpha=1/137, \qquad B_{\text{cr}}=\frac{m^2c^3}{e\hbar}\simeq 4\times10^{13}\text{ G}$$

Near the threshold (1) both $K^2_\perp$ and the refraction index tend to infinity. This singularity may be traced back to the fact that the spectra of electron and positron in magnetic field are partially discrete. The infinite behaviour of $K^2_\perp$ is just what we described as the resonance. Away from the threshold the dispersion curve in Fig. 1 approaches the sloping line $\omega^2/c^2=K^2_\perp+K^2_\parallel=\mathbf{K}^2$. The dashed line in Fig. 1 shows the real part of the dispersion curve in the region of absorption. The frequency here has an imaginary part which is responsible for pair creation. The analytical expressions for the real and imaginary parts of the dispersion curve in this region are given elsewhere[5]. Note that above the horizontal threshold line in Fig. 1 no pair creation by the photon is possible. Figure 1 relates to the case when the magnetic field is constant in magnitude and direction. The stronger the field, the larger is the gap between the two branches of the dispersion curves in Fig. 1:

$$\Delta K_\parallel\sim\left(\frac{\alpha B}{B_{\text{cr}}}\right)^{2/3}\frac{mc}{\hbar}\exp\left(-\frac{4B_{\text{cr}}}{3B}\right)$$

The flattening of the dispersion curve (2) near the threshold causes the group velocity component across the field $\nu_\perp = d\omega/dK_\perp$ to tend to zero when $K^2_\parallel \to (K^2_\parallel)_{\text{thr}}$ from inside the region $K^2_\parallel > (K^2_\parallel)_{\text{thr}}$, the energy of the photon thus being carried along the magnetic field. Previously a constantly-directed magnetic field was considered and this chanelling effect discussed as a refraction on its edge.[4,5]. With the present knowledge of the pulsar phenomena, however, it is more reasonable to consider a constant magnetic field B, but with curved lines of force, and a photon which appears inside it and is directed under a certain initial pitch angle

$$\psi_0=\tan^{-1}\frac{K_\perp(0)}{K_\parallel(0)}<\psi_1$$

with respect to the line of force. Assuming that the curvature radius of the line of force is much greater than the wavelength and other characteristic length parameters, we may also apply the above dispersion pattern to the present case of non-uniform magnetic field. Because the dispersive properties of the 'medium' are directionally non-uniform but constant in time, the frequency of the photon is conserved whereas its wave-vector components are not, and the photon 'travels' along its dispersion curve in Fig. 1. Classically one allows for the possibility that the photon may travel along the sloped straight line in Fig. 1, which is the empty space dispersion law. In this case the path of the photon in space is also straight. After the photon reaches the threshold line in Fig. 1 (when the pitch angle reaches the value $\tan\psi_1=(2mc/\hbar)(\omega^2/c^2-4m^2c^2/\hbar^2)^{-1/2}$, and crosses it) the pair creation becomes allowed kinematically.

However, as long as the dispersion law (2) may be taken seriously (restrictions will be discussed below), the photon travels along the true dispersion curve (solid line in Fig. 1) and never crosses the threshold. Its frequency remains real and the pair cannot be created in the experiment under consideration. This does not stop a photon creating a pair if the former has been prepared below the threshold line, for example, has appeared with the pitch angle exceeding ψ_1. The present situation is analogous to that known in the theory of polaritons[8]. Instead of creating the pair, the photon, in accordance with the above comment on the vanishing of $\nu_\perp$, should turn in the space along the magnetic field when approaching the threshold.

To describe the trajectory of the photon we restrict ourselves to the case of magnetic field whose strength is constant and lines of force are concentric circles. These simplifying assumptions allow us to solve the refraction problem analytically and produce a model sufficiently representative to allow the situation in the more realistic dipole magnetic field to be assessed. Within geometrical optics, the law of refraction may be derived using the fact that the photon travels in a medium whose refraction index is different in each spatial point depending on the direction of the magnetic field in it. For the special case under consideration and the photon moving away from the centre the infinitesimal form of the refraction law is $dK_\perp = K_\parallel\, d\alpha$ where $K_\parallel$ is understood as the function of $K_\perp$ given by equation (2). Taken in conjunction with the equations $dr=\nu_\perp\, dt$, $r\, d\alpha=\nu_\parallel\, dt$ which describe the motion of the centre of the wave packet, with **v**

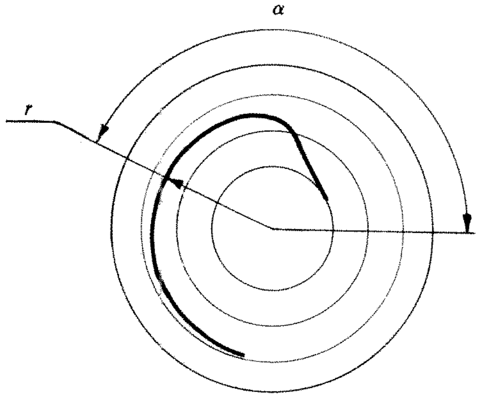

Fig. 2 The photon trajectory in a constant concentrical magnetic field (the solid line). The circles denote the lines of force.

being the group velocity

$$\nu_\perp = \frac{\mathrm{d}\omega}{\mathrm{d}K_\perp} = -\frac{c^2}{\omega}\frac{\mathrm{d}f}{\mathrm{d}K_\perp^2}K_\perp, \qquad \nu_\parallel = \frac{\mathrm{d}\omega}{\mathrm{d}K_\parallel} = \frac{c^2}{\omega}K_\parallel \tag{4}$$

this leads to the law of motion of the γ-quanta

$$t = \frac{\omega r(0)K_\parallel(0)}{c^2}\int_{K_\perp(0)}^{K_\perp}\frac{\mathrm{d}x}{K_\parallel^3(x^2)}$$

$$r = r(0)\frac{K_\parallel(0)}{K_\parallel(K_\perp^2)}, \tag{5}$$

$$\alpha = \int_{K_\perp(0)}^{K_\perp}\frac{\mathrm{d}x}{K_\parallel(x^2)}$$

Here the polar coordinates of the photon r, α and the time t are expressed as depending on the unique parameter $K_\perp$ which gives the corresponding position of the photon on the dispersion curve. The function $K_\parallel^2(x^2)$ is equation (2) using x^2 in place of $K_\perp^2$.

If the traditional dispersion law $K_\parallel^2 = \omega^2/c^2 - K_\perp^2$ is substituted into equations (5) the latter describe the photon propagating along a straight path with the constant speed c. If we approximate the dispersion law (2) by the broken line: $f(K_\perp^2) = -K_\perp^2$ for $K_\perp^2 < 4m^2c^2/\hbar^2$ and $f(K_\perp^2) = -4m^2c^2/\hbar^2$ for $K_\perp^2 > 4m^2c^2/\hbar^2$ we find that the photon moves directly until it gains the pitch angle ψ_1 (which happens at $r(t_1) = r_1 \equiv r_0[\omega^2/c^2 - K_\perp^2(0)]^{1/2}[\omega^2/c^2 - (4m^2c^2)/\hbar^2]^{-1/2}$), it then bends abruptly and propagates along the magnetic field (as now $\nu_\perp = 0$) with the constant angular velocity $(\mathrm{d}\alpha/\mathrm{d}t) = (c^2/\omega r_1)(\omega^2/c^2 - (4m^2c^2)/\hbar^2)^{1/2}$. For the very energetic γ-quantum $\hbar\omega \gg 4mc^2$, the group velocity $\nu_\parallel = c$ and $(\mathrm{d}\alpha/\mathrm{d}t) = (c/r_1)$. With the more exact function $f(K_\perp^2)$ (3) used in equation (5) the bending is less steep (see Fig. 2), the centre of the packet travels along a spiral which approaches asymptotically (from inside) the limiting circle, whose radius is

$$r(\infty) = r(0)\frac{K_\parallel(0)}{K_\parallel(\infty)} \equiv r_1$$

We call this phenomenon the capturing of γ-quantum by magnetic field.

Previously, we have been dealing with photons of only one polarization mode—that which has its electric field lying in the plane containing the magnetic field **B** and the direction of propagation K. The other mode whose electric field is orthogonal to this plane, has its first virtual pair creation threshold at

$$\frac{\omega^2}{c^2} - K_\parallel^2 = \frac{2m^2c^2}{\hbar^2} + \frac{2eB}{c\hbar} + \frac{2mc}{\hbar}\left(\frac{m^2c^2}{\hbar^2} + \frac{2eB}{\hbar c}\right)^{1/2}$$

and not at threshold (1), because the two particles created by the photon of this mode cannot both be in the ground state—one of them must occupy the first excited Landau level[5]. This level being unstable, the threshold level also acquires some width. However, this does not affect the above conclusions about capture. As for the pair creation it does occur but only through tunnelling and is suppressed to this extent.

Consider now the restrictions on the magnetic field necessary for the above treatment. As already noted, the direction of the group velocity changes abruptly in the bending point if one uses the broken-line approximation for the dispersion curve. It follows from equations (2), (3) and (5) that the time r during which this change occurs is about

$$r \sim \left(\frac{\alpha B}{B_{\mathrm{cr}}}\right)^{2/3}\frac{mc^2}{\hbar\omega}\frac{r}{c}\exp\left(-\frac{4B_{\mathrm{cr}}}{3B}\right)$$

The geometrical optics used above is justified if $rc \gg \lambda$, where λ is the photon wavelength. This is only if the magnetic field exceeds $\sim 0.1B_{\mathrm{cr}}$. Other restrictions on the magnitude of the magnetic field are supplied by the following consideration. The derivation of dispersion law (2) was based on calculations which formally treated the magnetic field as external, that is, one which does not undergo any recoil. This approximation should be subjected to an *a posteriori* verification. This reduces to checking whether a given magnetic field can indeed provide the momentum transfer necessary to make the photon follow the law of motion (5). The corresponding analysis indicates that approximately the same condition as above is sufficient to provide the capturing, whereas a lesser field is required to keep the photon on the trajectory along the field once it has been captured.

We now discuss the consequences of the capturing of the γ-quanta in the magnetospheres of pulsars. According to Sturrock's model[1] of pulsars there is a gap near their magnetic poles wherein the component of the electric field $E_\parallel$ parallel to **B** is nonzero and equal to $(\Omega h_{\max}/c)B_{\mathrm{P}} \simeq (\Omega R/c)^{3/2}B_{\mathrm{P}}$, where $\Omega = 2\pi/\mathrm{P}$ is the angular velocity of the pulsar, B_{P} is the magnetic field at its pole, R is the radius of the neutron star and $h_{\max}$ the length of the gap equal to $h_{\max} = (\Omega R/c)^{1/2}R$. Using this model one could explain the energy yield of the system: the pulsar NP0532–Crab Nebula[1,9]. A quantitative theory was also proposed which explains rather well the radiation spectrum of NP0532 and Crab Nebula[10,11]. However, the length of the gap[2] cannot in fact exceed the free path l_γ, which the γ-quantum of the curvature irradiation passes before converting into the e^+e^--pair, as the pairs created screen $E_\parallel$ and the length of the gap decreases to the value l_γ. For old (slowly rotating $P = 1$ s) pulsars, $l_\gamma \sim h_{\max} \sim 10^4$ cm, that is the pair creation does not affect the gap in this case. For fast rotating pulsars the path l_γ, when evaluated using the assumption of the straight-line propagation of the photons, is essentially $< h_{\max}$ for most of the γ-quanta of the curvature irradiation. For example, for NP0532 ($P = 0.033$ s) l_γ is less than $h_{\max}$ by ~ 1.5 orders. Consequently, in the framework of the existing theory of pulsars one cannot explain either the luminosity of Crab Nebula or that of the pulsar NP0532. The analogous difficulty is encountered, although to a lesser extent, with the pulsar PSR0833 − 45 in the remnant of Vela.

The effect considered here may overcome this difficulty. At $B \geqslant 0.1B_{\mathrm{cr}}$ the γ-quanta of curvature radiation generated by the primary particles are captured by the magnetic field and leave the gap region without having created pairs at the ratio sufficient for its screening. Later the γ-quanta leave the domain of strong field. As the field becomes insufficient to keep them in its orbit we go beyond the range in which the above consideration is valid. One may assume, however, that the γ-quanta are released and may create pairs; this would occur at the distance of several radii of the neutron star.

We thank Professor V. L. Ginzburg for helpful discussion.

New evidence for degassing processes during explosive eruptions

R. S. J. Sparks & S. Brazier

Department of Earth Sciences, University of Cambridge, Downing Street, Cambridge CB2 3EQ, UK

Measurements of pore size distribution in five samples of pumice, formed during explosive eruptions of plinian type, show three distinct sizes of vesicle. The characteristics of the three pore size populations are similar in the samples although they were collected from plinian deposits of five different volcanoes. We interpret the pore size populations as representing the degassing of silicic magma on three very different time scales. The coarse population (≫60 μm) represents slow vesiculation within the magma chamber over periods of weeks, months or years at small levels of gas supersaturation. The medium-sized population (50–5 μm) represents rapid vesiculation of magma on ascent to the surface during the plinian eruption over periods of minutes to hours. The fine population (5–0.5 μm) represents bubbles formed during explosive disruption of magma and rapid ejection into the atmosphere, involving short time scales (a few seconds), but large decompression rates.

The pore size distribution of five individual samples of pumice collected from plinian deposits was measured using mercury porosimetry[1,2] (a detailed description of the technique is given in ref. 2). The porosimetry method involves the forcing of mercury into a porous material under increasing pressure. The technique is based on the principle that when mercury is forced under pressure into a pore of characteristic dimension r and length l, an amount of work W is required which is proportional to the increased surface area exposed by the mercury at the pore wall. Theory[1] shows that the pressure P is related to the pore size, the surface tension of mercury γ and contact angle θ as follows:

$$P = (2\gamma \cos \theta)/r$$

The method allows the determination of pore size distribution from 300 to 0.003 μm, surface area per unit weight of sample for pores greater than any specified value, and an approximate estimate of density. The method strictly measures the dimensions of entrances to pores rather than the internal dimensions. Duplicate runs on the same material using this method typically show a standard deviation of mean pore size of only 2–3%. The actual shapes and dimensions of pores have been examined by scanning electron microscopy (SEM) for comparison. The present results are preliminary but are the first measurements of the detailed pore size characteristics of volcanic ejecta.

The five samples studied were collected from the 18 May plinian deposit of the 1980 eruption of Mount St Helens (STH15), the Avellino plinian deposit of Vesuvius (IT540), the 1975 plinian deposit of Askja volcano, Iceland (AS10), the plinian deposit of the Tierra Blanca tephra, Lago de Ilopango, El Salvador (TBJ) and the plinian deposit of the Bronze Age Minoan eruption of Santorini, Greece (MIN). Table 1 lists some relevant properties of the pumice samples and results of density and surface area determinations.

Figure 1 shows differential pore volume plotted against pore diameter. The most striking feature of the data is that three discrete ranges of pore size are observed in all five samples despite the different localities. The Vesuvius sample shows the same pattern although the glass composition is trachytic whereas the other four samples are rhyolitic. The relative volumetric proportions of the three populations differ from sample to sample. For example, the finest-size population is dominant in the Vesuvius and Tierra Blanca samples, but is subsidiary in the Minoan sample. However, measurements on two other samples of Askja pumice clasts show considerable variation in the amplitude of the three peaks. This implies that many more analyses would be required to demonstrate significant differences in the overall size population distribution of the five pumice deposits. From the distributions in Fig. 1 we separated each pore size population and plotted the data on a graph of log pore diameter against cumulative volume per cent. The range of pore sizes in each population, as measured by the diameters at the 16th, 50th and 84th percentiles on the cumulative plot, is strikingly similar

Table 1 Properties of pumice samples and results of density and surface area determinations

Sample	Locality	Composition	Density ($g\,cm^{-3}$)	Surface area ($cm^2\,g^{-1}$)
STH15	3 km east of Mount St Helens	Dacite with rhyolite glass	0.91	8.47×10^4
MIN	Thera Quarry, Santorini	Rhyodacite with rhyolite glass	0.81	0.79×10^4
IT540	Ottaviano Village, Vesuvius	Trachyte	0.62	8.04×10^4
TBJ	Lago di Ilopango, Nicaragua	Rhyolite	1.03	0.54×10^4
AS10	15 km east of Oskjuvatn Caldera, Askja	Rhyolite	0.69	5.57×10^4

The measurements of surface area are for all pores down to a nominal diameter of 0.003 μm.

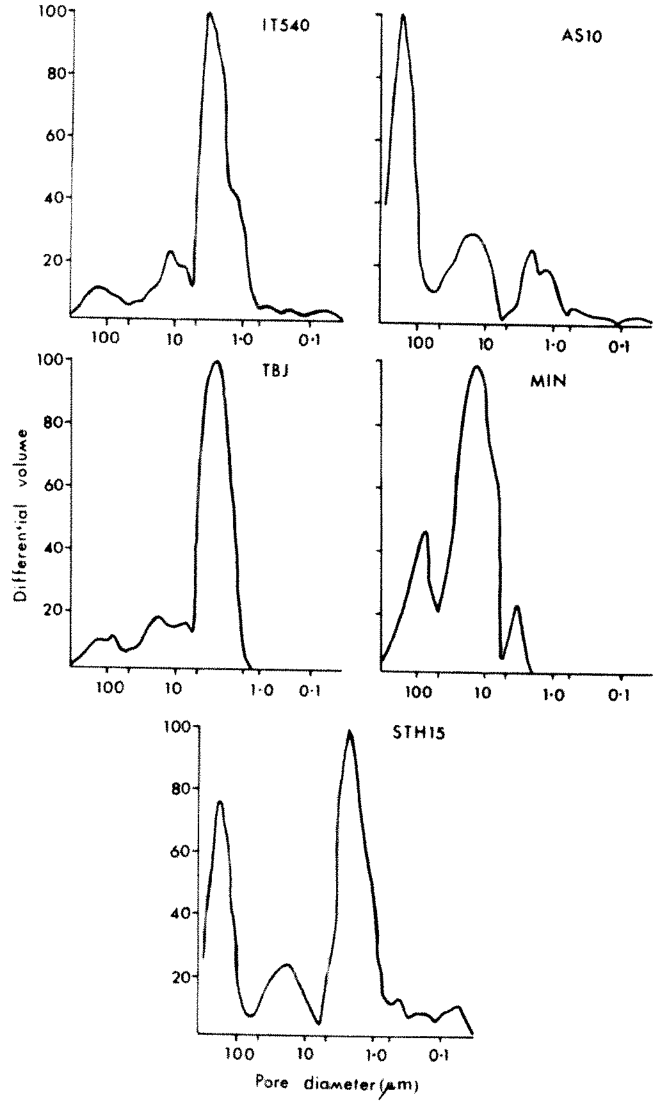

Fig. 1 Plots of differential volume against pore diameter for five pumice samples.

0028-0836/82/030218—03$01.00

for the five samples. Table 2 lists the median pore diameter, pore size range and pore volume per gramme of sample for each population. In three samples (IT540, STH15 and AS10) significant proportions of pore sizes are observed down to 0.02 μm (Fig. 1) whereas in samples MIN and TBJ there are no significant proportions of pore sizes beneath 1.0 μm. The porosimetry method only measures pores <300 μm across. Much larger vesicles are observed in all our samples. Consequently the coarsest population cannot be completely determined.

Examination of the pumice samples by SEM establishes that the pore dimensions determined by porosimetry are representative of the true sizes of vesicles. Furthermore the different size populations of vesicles are also apparent. Figure 2 shows micrographs of sample IT540. Figure 2*a* shows a group of vesicles in the approximate size range 10–20 μm surrounded by areas characterized by much smaller vesicles. Figure 2*b* illustrates an area of the smaller-sized vesicles which are typically in the size range 1–4 μm. The size ranges of the two groups of vesicles observed with the SEM are comparable with the middle-sized and fine-sized pore size populations (Table 2).

The three populations of pore sizes provide intriguing new evidence on the processes of degassing during major explosive volcanic eruptions. The occurrence of essentially the same pore size populations in samples from five different plinian deposits suggests a coherent pattern of degassing in this style of volcanic activity.

Models of explosive volcanic eruptions[3] involving high viscosity magmas recognize three stages of vesiculation. Before an eruption magma oversaturated in volatile components will form bubbles within the chamber. Bubbles can reach substantial dimensions because the time scale for growth can be large (weeks, months, years, even centuries), although the oversaturation pressure causing gas to diffuse into the bubbles may be small[4]. We suggest that the population of coarse pore sizes represents vesiculation of gas within the chamber before eruption.

The second stage of vesiculation occurs as magma ascends to the surface just before and during the eruption. Plinian eruptions typically last a few hours to a couple of days with discharge rates of magma in the range 10^3–10^5 $m^3 s^{-1}$ [ref. 3]. During this period magma is transported from depths of a few kilometres to near the surface where explosive disruption occurs. Models of this process[3,4] suggest that explosive disruption occurs at pressures of a few tens of bars. Thus the magma decompresses from a few kilobars to a few tens of bars in typical periods of many minutes to a few hours. We propose that the medium-sized population of pores are nucleated at this stage. We note that although decompression is rapid in this period, the loss of gas (assumed to be largely H_2O) from silicic magma causes a sharp increase in viscosity. For viscosities $>10^8$ poise bubble growth will be significantly retarded[4]. During this second stage the bubbles that had formed in the chamber will continue to grow by diffusion and decompression resulting in the clear separation of the two generations of bubbles observed in Fig. 1.

Table 2 Data on three pore size populations

Pore population	Sample	Median pore diameter (μm)	Pore volume ($cm^3 g^{-1}$)	Pore size range (μm)
	STH15	166	0.11	234–110
	MIN	98	0.14	173– 60
Coarse	IT540	119	0.07	202– 46
	TBJ	117	0.04	202– 71
	AS10	174	0.38	245–119
	STH15	20.1	0.09	37.0–10.5
	MIN	14.4	0.60	28.1– 7.8
Medium	IT540	12.3	0.21	27.9– 6.6
	TBJ	13.8	0.11	28.8– 6.3
	AS10	20.1	0.30	34.7–10.2
	STH15	2.04	0.37	3.05–1.10
	MIN	3.80	0.05	4.90–3.02
Fine	IT540	2.69	0.77	4.17–1.45
	TBJ	2.88	0.40	3.98–1.80
	AS10	1.91	0.25	2.91–1.17

The pore size range shows the 16th and 84th percentiles of each log normal distribution on a plot of cumulative volume versus pore diameter (see Fig. 1). The pore volume values are approximate estimates of the volume of each population group per gramme of sample.

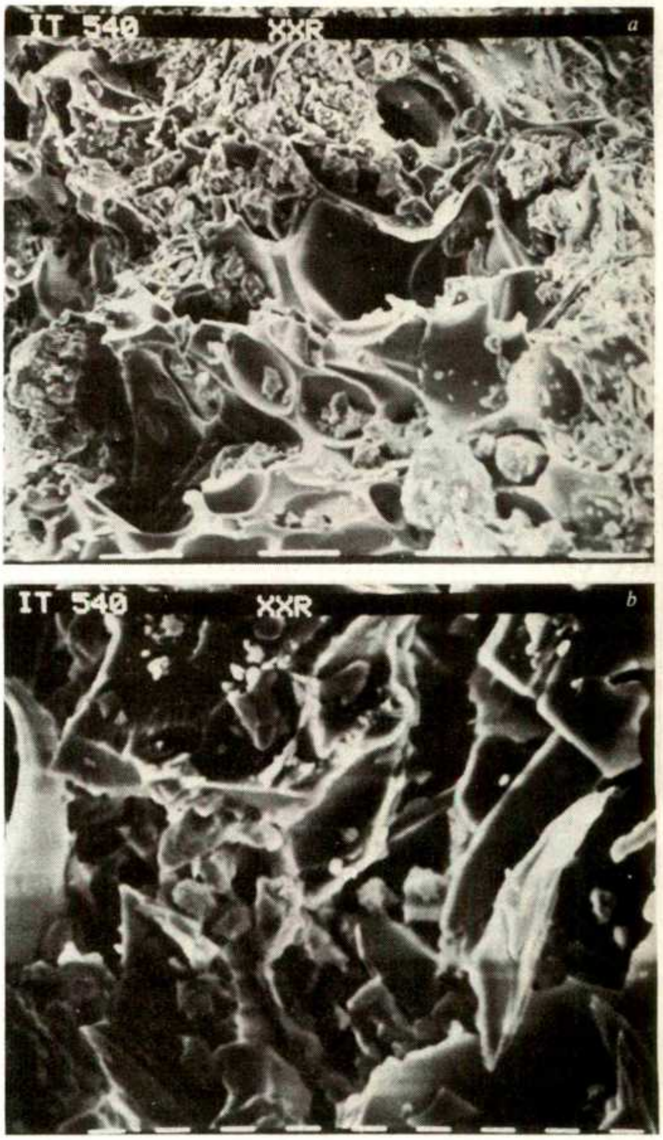

Fig. 2 Scanning electron micrographs of Avellino pumice sample (IT540). *a* Shows a group of large vesicles in the centre which correspond to the middle-sized pore pupulation and areas of small vesicles which correspond to the fine-sized pore population. Scale bars, 10 μm. *b* Shows an area of small vesicles which are prominent in the upper left-hand part of *a*. Scale bars, 1 μm.

The final stage of vesiculation occurs during explosive disruption of the magma into the atmosphere. Velocities of the order 300–600 m s^{-1} and decompressions of the order of a few tens of bars are attained during plinian eruptions[3]. Rapid quenching of disrupted magma (pumice and ash) occurs as cold atmospheric air is mixed turbulently into the explosion column. Time for bubble nucleation and growth is restricted to a few seconds. However, we propose that the large pressure drop nucleates a large number of small bubbles and that the population of fine pores forms at this stage.

The data reveal an unexpected and distinctive pattern of three pore size populations in plinian pumice clasts. The three periods of vesiculation proposed to explain these populations seem to be the most obvious explanation. However, much further work is required to confirm this hypothesis. If our interpretations of the data are correct, the degassing history of magma can be traced back into the chamber. We suggest that studies of pore sizes and surface area in volcanic ejecta may prove a fruitful way of studying the processes of volcanism. Studies of ejecta from different types of volcanic activity could provide new insights into volcanic mechanisms.

Measurements of pore size distribution were made on the Micromeritics Mercury Penetration Porosimeter Model MIC 9200 at Coulter Electronics Laboratory, UK. We thank R. Wenham for advice on the method and its interpretation. This research was carried out under NERC grant 6234.

Ice core sample measurements give atmospheric CO$_2$ content during the past 40,000 yr

A. Neftel, H. Oeschger, J. Schwander, B. Stauffer & R. Zumbrunn

Physics Institute, University of Bern, CH-3012 Bern, Switzerland

Recent measurements[1,2] on ice samples from Camp Century (Greenland, 77°10′ N, 61°08′ W), Byrd Station (Antarctica, 80°01′ S, 110°31′ W) and Dome C (74°40′ S, 125°10′ E) suggest that during the late part of the last glaciation the atmospheric CO$_2$ concentration was significantly lower than during the Holocene. Further investigation of this natural increase of the atmospheric CO$_2$ concentration in the past should aid our understanding of the climatic implications of the man-made CO$_2$ increase since the beginning of industrialization[3]. Here we report new and precise measurements of the CO$_2$ concentration of the air occluded in bubbles of ice samples from Camp Century and Byrd Station, using a new dry extraction technique. The extracted gases were analysed with an IR–laser spectrometer (IRLS). Samples from 22 different depths were analysed from each core. The samples are distributed over a depth interval corresponding approximately to the past 40,000 yr. In addition results for ice samples from selected depth horizons from a colder region (North Central, Greenland 74°37′ N, 39°36′ W) and from a warmer region (Dye-3, Greenland 65°11′ N, 43°50′ W) are given. Based on these results we estimate the trend of the atmospheric CO$_2$ concentration during the past 40,000 yr.

Samples of ~1 g were cut from the ice core with a band saw. The sample was placed into a cooled (−20 °C) container between two needle matrices. The system was then evacuated and the ice cube crushed by pressing the needle matrices against each other. The gas originally trapped in the bubbles of the ice escaped and flowed into an absorption cell, where the CO$_2$ concentration was determined using an IRLS. The crushing process was very quick and the absorption peak was measured repeatedly for a few minutes. The fast extraction and the continuous monitoring of the CO$_2$ concentration of the escaped gas allowed us to check whether the measurement was affected, for example, by a small leak or CO$_2$ contamination from the surface of the container (R. Z., A. N. and H. O., in preparation). The precision of the measurements was 1.5%. Between two and eight samples were measured at each depth.

To determine the total inorganic carbon content, ice samples of 300 g were melted in an evacuated glass container and the gases extracted for 7 h. The samples were analysed with a gas chromatograph[4]. If the melt water was alkaline, CO$_2$-free phosphoric acid was added to complete the extraction of CO$_2$. The total inorganic carbon content consisted of the CO$_2$ in the bubbles, the CO$_2$ dissolved in the ice matrix, the carbonates from dust incorporated in the ice and carbonates from the surface of the ice. Both the IRLS and the gas chromatograph were calibrated with three standard gases prepared by the Scripps Institution of Oceanography[5].

Figure 1 shows the measured CO$_2$ concentrations plotted against depth, together with a simplified $^{18}O/^{16}O$ ratio curve derived from the detailed curve given by Johnsen *et al.*[6]. The originally recovered Camp Century and Byrd Station cores are generally of poor quality between the 400 and 1,200 m depths and the ice is heavily fractured. In these depth intervals the measured CO$_2$ values exhibit large scattering. This might be due to contamination by drilling fluid, a mixture of diesel fuel (88%) and trychlorethylene (12%), penetrating through small cracks into the ice. In these fractured ice zones, we measured several samples at each sample depth. Its small size meant that the sample was probably uncontaminated and we conclude that the lowest CO$_2$ values best represent the CO$_2$ concentrations of the originally trapped air of these depth intervals. In the larger samples (300 g) contamination is almost inevitable and the measured CO$_2$ concentrations tend to be higher than the air originally occluded in the ice. This is one reason for the high CO$_2$ values obtained during the climatic optimum given by Berner *et al.*[1] for the Camp Century core.

The CO$_2$ concentrations measured on 22 samples spaced over 11 cm from the 103-m depth, from North Central (Greenland), a colder location than Byrd Station and Camp Century, have a mean value of 271 p.p.m. The standard deviation of the measurements is only 9 p.p.m. This depth horizon corresponds to an age of ~680 yr. The gas enclosure occurs between 60 and 80 m corresponding to an age interval of 350–500 yr.

Figure 2 shows the CO$_2$ concentration variations measured on a 13-cm long ice core segment drilled in 1979 at Dye 3 (Greenland)—a location that is subject to frequent summer melt at the surface. Figure 2 thus shows the increased CO$_2$ concentrations that are usually associated with a melt feature.

Cold ice which forms by diagenetic processes and sintering of cold dry snow contains samples of atmospheric air in the bubbles. (This has also been shown for N$_2$, O$_2$ and Ar (ref. 7).) The results of the samples from North Central show that reproducible values are obtained for the CO$_2$ content using our improved extraction technique.

Due to atmospheric mixing, the CO$_2$ concentration in the Northern and the Southern Hemispheres should not differ by more than a few p.p.m. (ref. 8). For corresponding times one would expect the same CO$_2$ concentration in the bubbles in very cold ice from Antarctica and Greenland. Indeed, the CO$_2$ results of Camp Century and Byrd Station agree qualitatively. In both cores the decrease of the CO$_2$ content corresponds to the $\delta^{18}O$ decrease which marks the transition from the Wisconsin to the Holocene.

However, there are differences between the Byrd Station and the Camp Century values which exceed the analytical errors. The higher CO$_2$ values in the Camp Century core during the Holocene may be due to the influence of melt water during the ice formation. In fact many melt layers have been observed in the Camp Century core (C. Langway and H. Clausen, personal communication). If meltwater is involved during the ice formation, the CO$_2$ concentration in the bubbles increases as shown by the results from the Dye 3 sample (Fig. 2). Although a detailed stratigraphical examination for the melt features was not made in the Byrd ice core the overall melt in this core is substantially less than recorded in the Camp Century core (C. Langway, personal communication). Therefore, for the Byrd core this effect should be negligible. At the end of last glaciation, when the CO$_2$ concentration was at a minimum, the Camp Century CO$_2$ concentration in the bubbles was slightly lower than those from the Byrd core. During this time the impurity content in the Camp Century core is an order of magnitude higher than in the

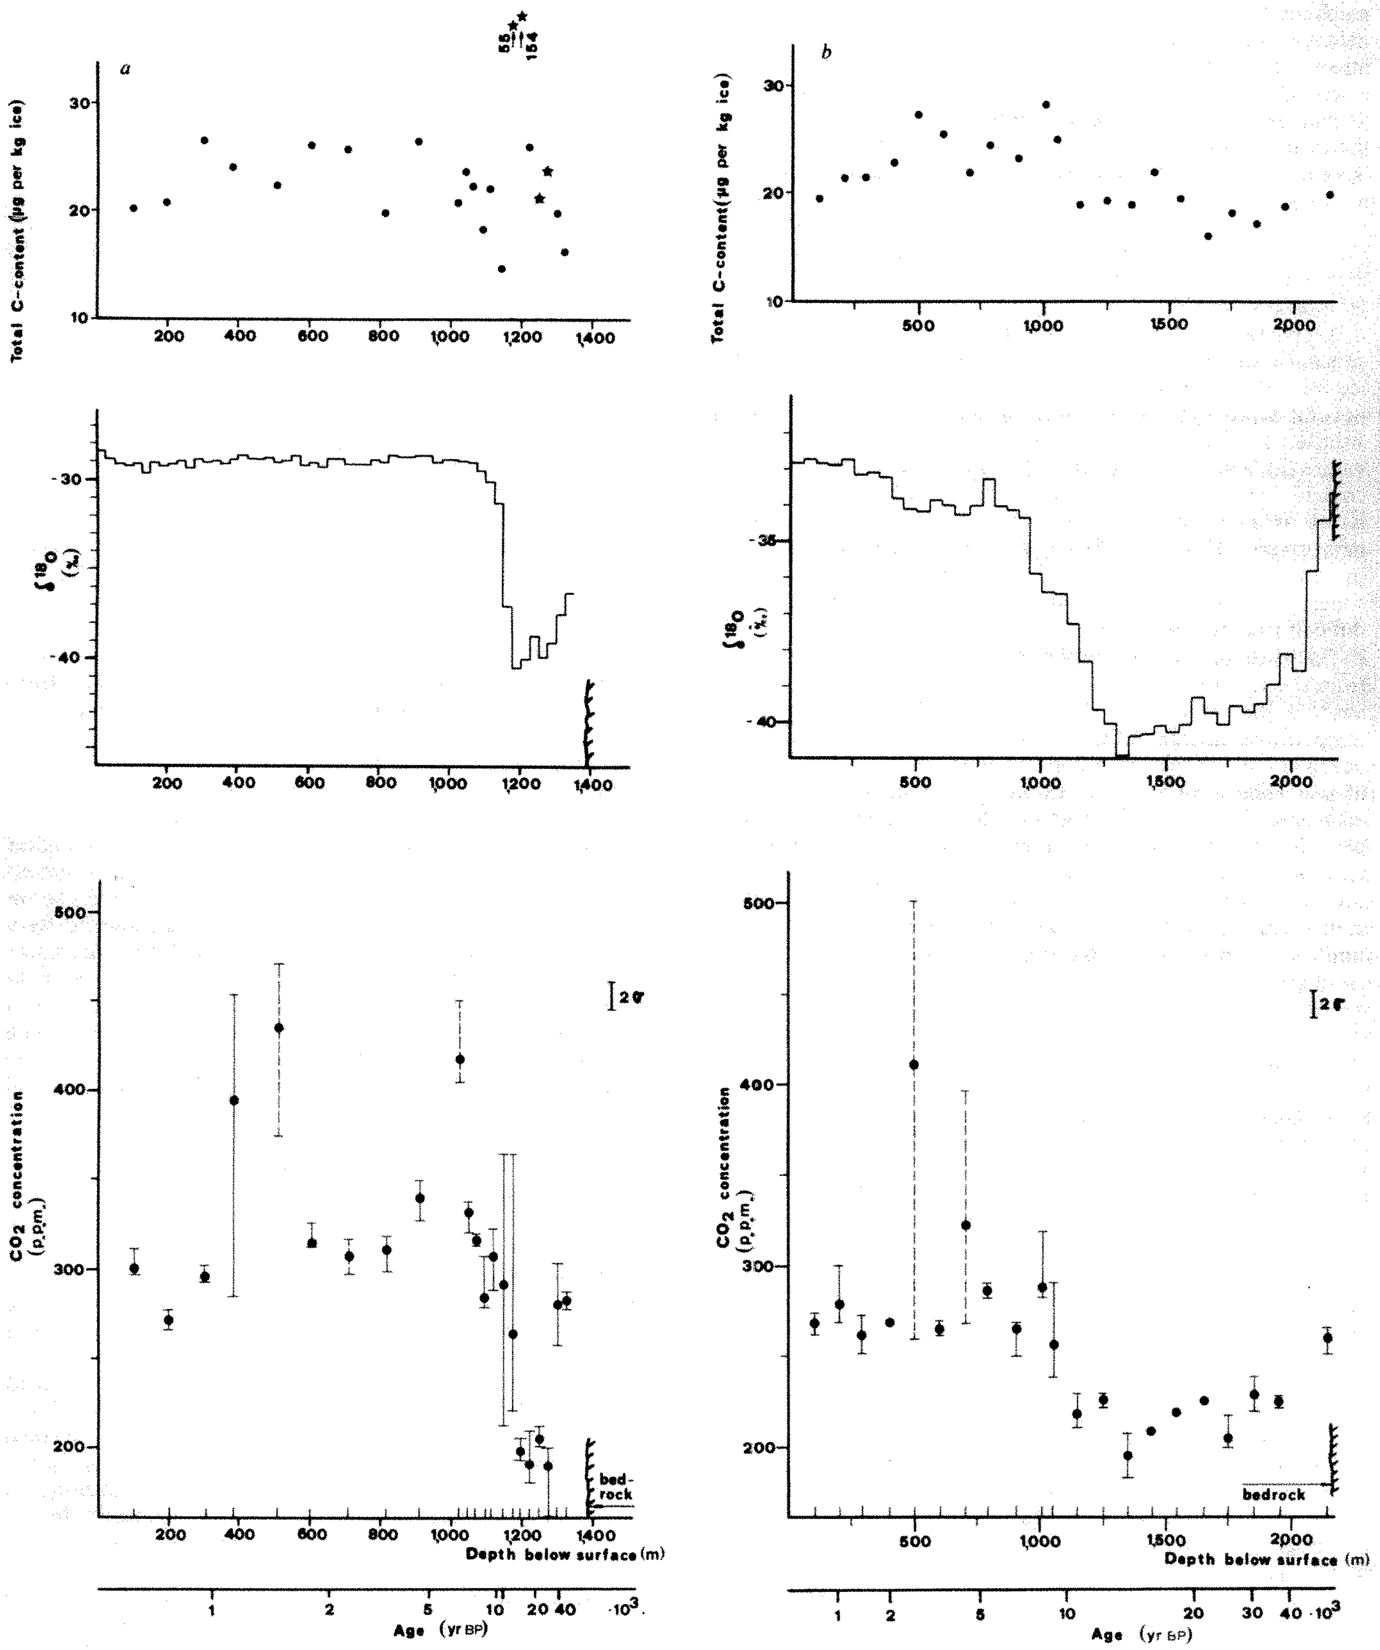

Fig. 1 CO_2 concentrations in the bubbles and total carbonate content of: *a*, the Camp Century core; *b*, the Byrd core. The CO_2 concentrations are presented with the lowest, highest and median values for each depth. The dashed lines indicate depths where drill fluid was observed in the large samples. All samples marked by a star were alkaline and acid was added during the wet extraction.

Holocene[9] and the melted ice samples are alkaline. At present, we cannot rule out the possibility that the alkaline ice matrix absorbs a minor fraction of the CO_2 in the bubbles. Such a mechanism would explain the slightly lower Camp Century values for this period. While the carbonate content is an order of magnitude higher in Camp Century ice at the end of last glaciation than during the Holocene (Fig. 1), it remains almost unchanged in the Byrd core. The qualitative agreement between the two CO_2 concentration time series rules out the possibility of large interaction between CO_2 in the bubbles and the carbonates in the ice.

Note that the oldest samples in the Byrd Station and Camp Century cores (near the bottom of the ice sheets) again exhibit higher CO_2 values which are of the same magnitude as the Holocene values.

A generalized estimate of the history of atmospheric CO_2 concentration is shown in Fig. 3. The age of the Camp Century ice was calculated according to the method of Hammer *et al.*[10]. Several depth–age relationships for the Byrd core are given by Johnsen *et al.*[6]. We selected the time scale for Byrd Station, where the $\delta^{18}O$ decrease from the Holocene to the Glaciation coincides with the $\delta^{18}O$ decrease in the Camp Century core, that is, we assume the climatic events to be synchronous in both hemispheres. Due to the low data density and the uncertainties in the age calculations the estimate of the atmospheric CO_2 range in the oldest sections of the ice cores are more difficult to ascertain.

The increase of the atmospheric CO_2 content at the transition from the Ice Age to the Holocene and its climatic implications has to be discussed with regard to the global carbon system. The temperature change of the sea surface water and the change of ocean volume at this transition accounts for only a 5% increase of atmospheric CO_2 concentration[11]. Both cannot explain the measured CO_2 increase of a factor 1.2–1.4 between the two time periods. The atmospheric CO_2 level depends on the carbonate chemistry of the surface ocean water, especially on the concentration of dissolved inorganic carbon (DIC) which in turn is controlled by biological productivity. Biological activity is limited by the amount of phosphorus available. Broecker links the atmospheric CO_2 increase at the Glacial/Holocene transition with a change in the phosphorus available[12]. He considers the following sequence of events. At the transition a higher sedimentation rate of organic material decreases the amount of phosphorus in the seawater. This leads to less biological productivity and therefore the difference in DIC between surface water and deep water decreases. This leads to a higher concentration of DIC in the surface layer and a higher atmospheric CO_2 concentration. The difference in DIC concentration between surface water and deep water is accompanied by a difference in $\delta^{13}C$ of the DIC. Simultaneous $\delta^{13}C$ measurements on foraminifera living at the surface and at the sea floor do indicate a higher vertical $\delta^{13}C$ gradient during the Glacial than during the Holocene, which agrees with Broecker', theory. The measurements of $\delta^{13}C$ values in the CO_2 gas extracted from ice samples could help us to understand the mechanisms which lead to the atmospheric CO_2 variations during climatic change.

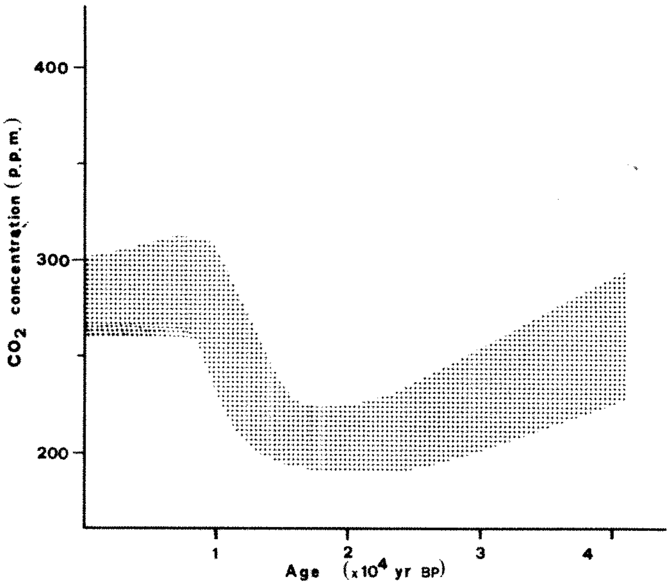

Fig. 3 Estimate range of atmospheric CO_2 during the past 40,000 yr.

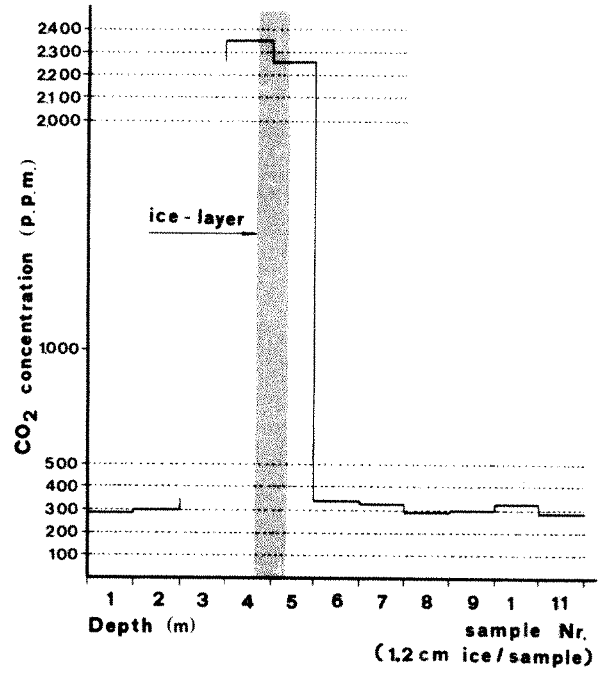

Fig. 2 CO_2 concentration in the bubbles of a 13-cm piece at a depth of 124 m of the Dye 3 core (southern Greenland).

Because CO_2 absorbs IR radiation, it is an important gas in the global radiation budget. Climatic models predict a global warming of between 1.5 and 4 °C for a doubling of CO_2 concentration in the atmosphere[13]. The relationship between the global temperature change and the CO_2 concentration change is approximately logarithmic[14]. A change in the atmospheric CO_2 concentration of 30% would lead to a global warming of $0.9 \pm 0.5°$. It has been reported that the global warming at the Glacial to Holocene transition was at least 2.3 °C (ref. 15). It therefore seems that the CO_2 increase alone was not large enough to explain all this global warming. Considering part of the temperature increase is due to an albedo change by a diminished ice or snow covered surface, the increased CO_2 level in the atmosphere contributes significantly to the global warming at the transition from the last glaciation to the Holocene. In this context it would be interesting to know whether the CO_2 increase preceeded or followed the temperature change. Our data suggest that the time lag between the CO_2 increase and the climatic change cannot have been more than ±2,000 yr.

More accurate estimates of the atmospheric CO_2 history will be possible when samples from very cold locations, such as the South Pole, become available.

We thank Drs C.C. Langway, B.L. Hansen, H. Clausen and Professor W. Dansgaard who envisaged the potential of ice cores for studies of this kind and made them available for the present investigation, also Dr U. Siegenthaler for valuable discussions. This work was supported by the Swiss NSF the

Steroid hydrocarbons and the thermal history of sediments

A. S. Mackenzie*, N. A. Lamb & J. R. Maxwell

Organic Geochemistry Unit, University of Bristol,
School of Chemistry, Cantock's Close, Bristol BS8 1TS, UK

Assessment of the extents to which certain organic chemical reactions have occurred in sedimentary rocks with increasing burial depth and the associated temperature rise, can distinguish differences in the extent of their thermal maturation[1–10]. Heating experiments with sediments have suggested that these different reaction types have different kinetic constants[11]. Therefore, a measurement of the extent to which one reaction type has occurred might be expected to correspond to different values of a measurement based on a different reaction type, depending, for example, on the average sedimentary heating rate (°C Myr^{-1})[12] of the sample. We use here two reaction types to investigate this hypothesis: (1) configurational isomerization in steroid alkanes, represented by the conversion of the biologically inherited configuration, 5α(H), 14α(H), 17α(H), 20R, in a C_{29} sterane to an approximately equal mixture of itself and the corresponding 20S configuration formed in the sediment[6,13]; and (2) apparent aromatization of two C_{29} monoaromatic steroid hydrocarbons (Fig. 2) assumed to be isomeric at C-5 (refs 14–21), based on retention time comparisons with synthesized C-27 analogues, to a presumed product, the C_{28} triaromatic steroid hydrocarbon[9,14]. Comparison of the extents to which these two reactions have occurred in suites of sediment samples has allowed three basins [Pannonian Basin (Pliocene), Mahakam Delta (Miocene), Paris Basin (Toarcian)] with different thermal histories to be distinguished. Extension of the hypothesis to two other sedimentary sequences suggests a higher average heating rate for the Oligocene of the Zhanhua Depression (north-east China) than for the Cretaceous of the Wyoming Overthrust Belt.

The thermal history of a sediment, that is, the temperature versus time profile since deposition, is important for estimating the time at which the sediment was capable of generating petroleum[22] A simple means of describing thermal history is the average heating rate, defined as the product of average sedimentation rate (km Myr^{-1}) and geothermal gradient (°C km^{-1})[12] Table 1 lists the rates (based on present depth/age) for three sample suites (1) 12 Pliocene shales from a borehole in the Pannonian Basin in south-east Hungary[23], (2) three shales and six coals from boreholes around the Handil oilfield of the Mahakam Delta, Kalimantan, Indonesia[24], and (3) 14 Toarcian shales sampled from outcrops and boreholes across the Paris Basin[6 25] Although different types of organic matter occur in the sequences[23–25], the present comparison is valid because the carbon skeletons of the products of the reactions are only formed by thermal maturation and not by biological processes. Where there has been a period of erosion [(2) and (3)] corresponding heating rate values are given in Table 1, which do not include the periods of erosion In either case there are major differences in heating rates over the three sample suites

All the samples contain complex mixtures of stereoisomers of steroid alkanes with both a non-rearranged and a rearranged carbon skeleton, covering a range of carbon numbers[2 5,6,26], and can be partly separated by combined gas chromatography–mass spectrometry (GC–MS)[5 6] The complexity of the mixture increases with increasing thermal maturation due to isomerization at various chiral centres in skeletons[6] Using non-polar GC columns the ratio (%) of the unresolved mixture[26] of the 24R and 24S isomers of (20S)-24-ethyl-5α(H), 14α(H), 17α(H)-cholestane to itself and the corresponding 20R mixture can be measured from the appropriate peak areas in GC–MS fragmentograms of the ion *m/z* 217 (refs 5, 6) (Fig 1) The value of this measurement rises from zero in very immature sediments to a maximum of ~50–55% in mature sediments[5 6], that is the equilibrium constant is ~1, although it may vary slightly with temperature

The samples also contain complex mixtures of monoaromatic and triaromatic steroid hydrocarbons The latter are thought to derive from the monoaromatics as a result of thermal maturation[9 14] The ratio (%) of the C_{28} triaromatic component in Fig 2 to itself and two presumed precursors, thought to be the 5α and 5β(H) isomers of the C_{29} component in Fig 2, can be measured from mass fragmentograms of the ions *m/z* 231 and 253 respectively[9] The two C_{29} monoaromatic components are suggested to be the 5α and 5β(H) isomers of the structure in Fig 2, the assignment being based on 400 MHz ^1H NMR analysis of a 1 1 mixture (GC analysis) of two stereoisomeric ring C monoaromatics isolated from acidic treatment[27] of cholesta-3,5-diene Comparison of chemical shifts with literature compounds[14–19] in conjunction with decoupling and n O e experiments indicates (1) ring C is aromatic (confirming the *m/z* 253 base peak in the mass spectra[15]), (2) there is a methyl group at C-17, consistent with the structures in the triaromatic series[9 14,16], and at C-10, (3) the A/B ring junction is *trans* with the 10β(CH_3), 5α(H) stereochemistry, (4) the 1 1 mixture results from isomerism at C-17 or C-20, that the latter is the case is suggested both by the structures and distribution of the low-molecular weight triaromatics[9] and by the method of preparation[27] The two isomers coeluted (GC–MS) on OV-1 and Carbowax 20M with two major C-27 monoaromatics in the aromatic fraction of Semécourt shale (Paris Basin, see Fig 3*a*) The other two major C-27 monoaromatics in this fraction are inferred to be the 5β(H), 20R and 20S isomers Comparison of elution orders of the C-27 and C-29 monoaromatic components suggests that the two C-29 components used in the measurement are those in Fig 2 [before completion of this work it came to our attention that certain monoaromatic hydrocarbons of this structural type had been assigned and found to occur in sedimentary rocks and petroleum (W K Seifert and J M Moldowan, personal communication). The above conclusions are also consistent with structual assignments reported

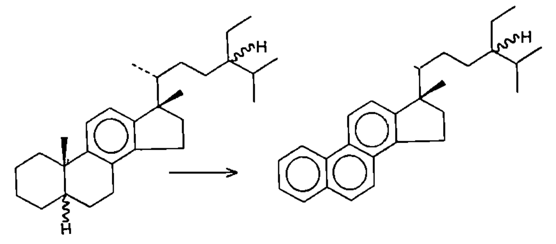

Fig. 2 Proposed aromatization of the 5α(H) and 5β(H) isomers of (24R+24S)-(20R)-24-ethyl-17β-methyl-18-norcholesta-8, 11,13-triene to (24R+24S)-(20R)-24-ethyl-17β-methyl-18,19-dinorcholesta-1,3,5(10),6,8,11,13-heptaene (numbering based on steroid skeleton)

recently[20,21]] Again the 24R and 24S isomers are not resolved on non-polar columns in the conditions used The maximum value of the measurement is ~100% (ref 11), and values as low as zero can occur in immature sediments[9]

Figure 3*a* shows the isomerization measurement plotted against the aromatization measurement for the three sample suites In the Paris Basin Toarcian shales, whose values and maximum burial depths have been reported previously[6 9], there is a steady increase, with some scatter, in both measurements with increasing burial depth such that the presumed end points of both reactions are approached in the two deepest shales Heating an immature Toarcian shale at elevated temperatures in the laboratory resulted in aromatization values approaching the deepest shales, whereas only minor changes were observed in the extent of isomerization at C-20 in the steranes[11] It has been suggested that the rate of aromatization of the monoaromatic steroid hydrocarbons is more temperature dependent than the rate of isomerization of 5α(H), 14α(H), 17α(H)-steranes at C-20 (ref 11)

Although the two reactions seem to have similar average rates at the lower temperatures (<100 °C) experienced by the Toarcian shales (Fig 3*a*), comparison with the laboratory experiments (201, 257 °C) suggests that the aromatization reaction occurs at a faster relative rate at higher temperatures If the reactions follow pseudo first-order kinetics, then according to the Arrhenius equation, the rate constant for the aromatization of steroid hydrocarbons would appear to have higher values of activation energy and pre-exponential factor than the isomerization at C-20 in 5α(H), 14α(H), 17α(H)-steranes ($\log_e k = \log_e k_0 - E/RT$, where k = reaction rate, k_0 = pre-exponential factor, E = activation energy, T = absolute temperature and R = gas constant)

This hypothesis has been examined by comparing the extents of the two reactions in the Toarcian shales with the sample suites from the Pannonian Basin and Mahakam Delta (Fig 3*a*) The Pliocene of the Pannonian Basin has average heating rates at least 20 times higher than the Paris Basin Toarcian shales (Table 1) Details of aspects of the sedimentation and petroleum geochemistry of the Pannonian borehole have been reported elsewhere[23] The four shallowest samples (between 2,051 and 2,500m) show a trend (Fig 3*a*) of enhanced aromatization relative to isomerization akin to that seen in the laboratory heating experiments[11], the aromatization (more temperature dependent) reaction is effectively complete by sample 4 (2,500m, ~105 °C present temperature) At this depth the isomerization (less temperature dependent, and more time dependent) has reached a value of only 16% of the 20S isomer as a proportion of the C_{29} 5α(H), 14α(H), 17α(H)-steranes (Fig 3*a*) High values (~50–55%) in the curve are not reached until a further depth increase of ~800m (3,328m, sample 15, 137 °C) The coal and shale samples from the Mahakam Delta derive from boreholes around the Handil oilfield Detailed information about the geology and geochemistry is given elsewhere[24 28] The heating rate represents an intermediate situation between the Paris and Pannonian Basins (M Vandenbroucke, personal communication) The path followed by the Mahakam Delta samples seems to reflect this intermediacy, although the Der sample from the Paris Basin has similar values to Mahakam samples 3, 9 and 10 The apparently anomalous behaviour of Der (and perhaps Colombotte) may relate to the fact that the Paris Basin samples derive from a wide geographical area[6] and that Der (and Colombotte) may have experienced a period of higher sedimentation[29] not apparent from a study of the present record of sedimentation[30]

Average sedimentary heating rates can only reflect the overall thermal history of a sequence It might be expected, however, that the molecular measurements could also reflect variation in the heating rate at a later stage If the heating rate declines markedly, or even if cooling occurs, the decrease in the rate of the isomerization reaction (less temperature dependent) would be less than the decrease in the rate of the aromatization reaction (more temperature dependent) During such a period, a trend reflecting a high heating rate such as in the Pannonian Basin (Fig 3*a*) would be displaced towards the Paris Basin trend In the case of the Mahakam Delta suite, the samples have experienced heating rates of at least 30 °C Myr^{-1} (M Vandenbroucke, personal communication) during the late Miocene, which are much greater than the average values for the Pannonian Pliocene Since then, they declined such that they never exceeded 3 °C Myr^{-1} during the late Pliocene and subsequent cooling of the samples has occurred during the past 3 Myr, because ~300m has been eroded from the sequence studied (M Vandenbroucke, personal communication). These events explain both the occurrence of samples of late Miocene age at the same depths as late Pliocene Pannonian samples, and the proximity of the Paris Basin and Mahakam Delta trends (Fig 3*a*) which are not obvious from the heating rate differences (Table 1)

Figure 3*b* includes the two measurements plotted for (1) six Cretaceous shales from the Wyoming Overthrust Belt[13], all but one are shallow (20–40m) core samples and derive from a sequence of increasing age within a single thrust slice Calculation of average heating rates is difficult because of the structural complexity of the area[31], (2) six Oligocene (Shaheji) cored shale samples from the Zhanhua Depression in north-east China, of varying burial depth and location[32] Because the area

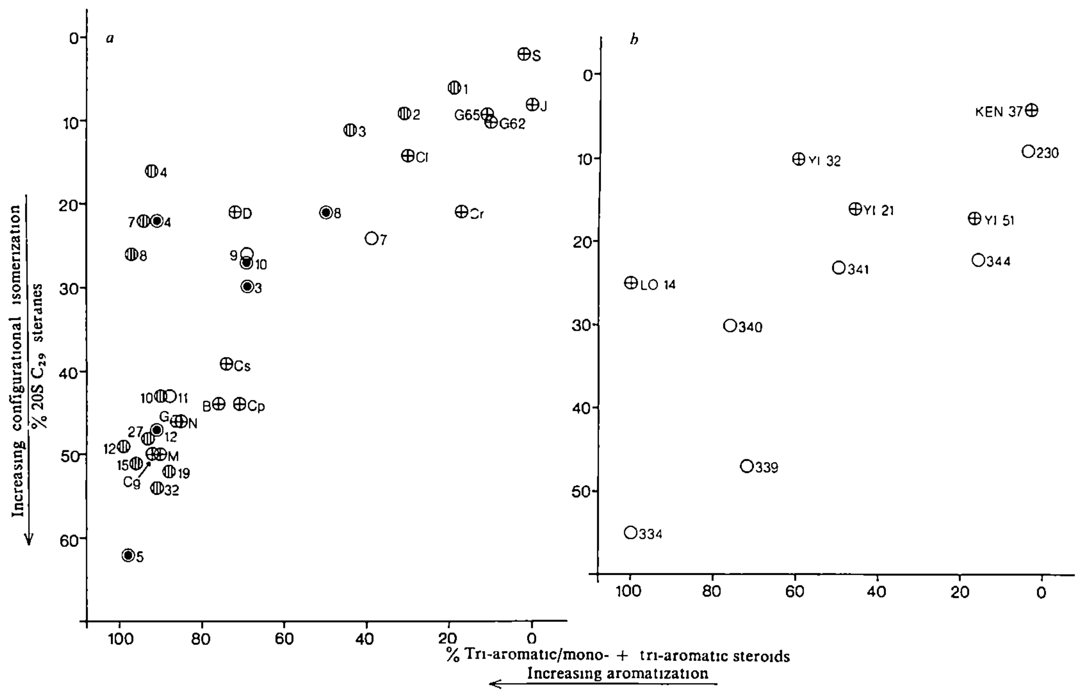

Fig. 3 Plots of the extent of isomerization at C-20 in C_{29} steranes (Fig 1) against the extent of aromatization of C_{29} monoaromatic to C_{28} triaromatic steroid hydrocarbons (Fig 2) for *a*, (maximum burial depths in brackets, where available) Toarcian shales of the Paris Basin (⊕) where S, Semécourt (700m), J, Jouy (700m, G62, G6-2-2 (600m), G65, G6-5-6 (600m), CI, Colombotte (500m), Cr Creveney (500m), D, Der (1,280m), Cs, Cesarville (2,040m), Cp, Coupvray (2,100m), G, Grandville (2,100m), N, Nangis (2,130m), B, Belou (2,207m), M, Montmirail (2,433m), Cg, Courgivaux (2,460m) Miocene coals (●) and shales (○) from the Mahakam Delta (Handil field except 3,4,5) where 7 (2,285m), 8 (2,283m), 9 (2,538m), 10 (2,537m), 11 (2,903m), 12 (2,905m) For samples 3, 4, 5 only T_{max} values[39] are available and are 430, 440 and 448 °C respectively (M Vandenbroucke, personal communication) Pliocene shales and siltstones from a borehole in the Pannonian Basin (⦶) where 1 (2,051m), 2 (2,291m), 3 (2,386m), 4 (2,500m), 7 (2,702m), 8 (2,759m), 10 (2,953m), 12 (3,098m), 15 (3,328m), 19 (3,548m), 27 (4,269m), 32 (4,888m) *b*, (Present depths) Cretaceous shales (○) from Wyoming Overthrust Belt (all shallow core samples (20-40m) except 334, present depth 2,760m) Oligocene (Shahejie) shales from the Zhanjua Depression (⊕), present burial depths in brackets), Ken 37 (1,850-1,860m), YI 51 (2,339m), YI 21 (2,758m), YI 32 (2,899m), LO 14 (2,978m) The isomerization for LO 14 is an average of the C_{29} measurement and the corresponding measurement for the C_{27} skeleton, because there is a reworked component in the steranes with a very high relative abundance of C_{29} steranes[32]

which was sampled has been affected by faults active till the Quaternary, and the samples are from separate boreholes of different location separated by up to 15 km, they presumably have some differences in their average heating rates, the range of which is difficult to estimate Although the sample coverage is less extensive than in the other sequences (Fig 3*a*), measurements suggest that the Overthrust Belt shales (Fig 3*b*) have a similar average heating rate to the Paris Basin samples (Fig 3*a*), whereas the Zhanhua Depression shales seem to have had a recent heating experience of a similar order to that which has affected the shallow Pannonian Pliocene samples Such observations are consistent with available geological information for the two areas[31 32]

Comparison of proposed maximum temperatures for the Pannonian[23] and Paris[33 34] Basins provides further evidence that the aromatization has the greater temperature dependence For a given aromatization value the maximum temperature difference in samples from the two basins is of the order of 10 °C, whereas for a given isomerization value differences of up to 60 °C are apparent

Confirmation and extension of the hypothesis requires (1) determination of the appropriate activation energies and pre-exponential factors, both from laboratory heating experiments[11] (with consideration of the difficulties involved[35]) and from integration with mathematical models for the evolution of sedimentary basins[36 37], which include temporal variations in sedimentation rate and heat flux Preliminary studies of the latter type, using estimated kinetic constants for the reactions, suggest that the trends (Fig 3) follow S-shaped curves (A S M amd D P McKenzie, unpublished results) (2) An examination of the effect which extreme differences in lithology could have on the measurements In the present study, all the samples are shales or silt-stones except for the six coal samples from the Mahakam Delta in which little significant variation was observed between the coals and shales from comparable depths (Fig 3*a*) (3) A search for other measurements which might preserve a record of earlier high heating rate events, although subsequent lower heating rates and/or cooling result in a trend which suggests an overall low average heating rate (see Mahakam)

Care should be taken with the measurements the mixtures are complex and overlap with other components can occur Attention should be paid to peak shapes in various diagnostic fragmentograms, to examination of full mass spectra when required, and to the potential presence of migrated components

This approach has not been extended to a study of crude oils, where migration and subsequent thermal effects in the reservoir (as opposed to those in the source rock) could affect the measurements Preliminary studies[13 32 38] suggest that the configuration at C-20 is not altered significantly by either process, although the proportion of triaromatic to monoaromatic steroid hydrocarbons can decrease in certain cases with increasing distance of secondary migration (unpublished results on Mahakam Delta oils)

If the hypothesis is correct there are other implications For example, there is no reason why variation in the reflectance of vitrinite, commonly used to determine the onset of petroleum generation in sediments, should follow the same kinetic behaviour as the petroleum generation process Reflectance values are different for the threshold of petroleum generation from different types of organic matter[22], but the hypothesis suggests that there may also be differences within a single type of organic matter, depending on heating rate differences

We thank the following for providing samples, geological information and/or GC–MS measurements (recorded in this laboratory in similar conditions and in identical conditions within each suite) Drs B Durand and M. Vandenbroucke (Paris Basin), Drs J M Moldowan and W K Seifert (Overthrust belt), Dr J Oudin (Mahakam Delta), Dr Cs Sajgo (Pannonian Basin), and Dr Shi Ji-yang (Zhanua Depression) We also thank the NERC (GR3/2951 and GR3/3758) for GC–MS facilities and for a fellowship (A S M), the SRC for a Studentship (N A L), Mrs A P Gowar for technical assistance, and Mr C F Hoffman for synthesizing certain triaromatic steroid hydrocarbons and Mr T A Carpenter for 400-MHz data and valuable discussions

Massachusetts 02543, USA

The isotopic composition of Sr and Nd in oceanic basalts reflects the character and chemical evolution of their source regions with respect to Rb/Sr and Sm/Nd. Combined studies of the Sr, Nd and Pb isotopic systems in mid-oceanic ridge basalts (MORB)[1,2] have confirmed previously recognized heterogeneities on a relatively large scale for the oceanic mantle. These heterogeneities have been ascribed to both long- and short-lived mantle processes and to mixing between enriched and depleted mantle sources (for example, see refs 1–4). However, data for the mid-Atlantic ridge (MAR) remote from known hot spots are available for only 14 samples of which only 3 are basaltic glass, the most 'reliable' sample type. Thus, attempts to explain MORB mantle heterogeneities are founded on limited data and remain largely speculative. The extent of variation in isotopic composition of 'normal MORB' over a limited area of the MAR is critical to any isotopic model for the oceanic mantle. Using high resolution seafloor mapping and sampling techniques, we can evaluate isotopic composition on a fine scale both within a ridge segment and across the fracture zones terminating that segment. We report here studies of a series of basaltic glass samples from the MAR intersection with the Kane Fracture Zone located at 22°–24° N (Fig. 1) which have implications for the dynamics of mantle melt segregation and the role of a major transform in mantle convection.

The Kane Fracture Zone is particularly interesting as it is one of the few areas of the MAR where the basalts are interpreted to represent 'normal MORB' and for which geochemical data indicate a relatively simple history of fractional crystallization and partial melting[5] The basalts of the Kane Fracture Zone do not display geochemical complications such as crossing rare-earth element patterns and complex mixing relationships that have been identified for the MAR axis north of 30° N (refs 6, 7) In addition, phase relations and geochemical models[5] indicate that, in many cases, the magma batches that erupted in the 22°–24° N region have evolved independently, and mixed only over a limited geographical area This minimizes the likelihood that large magma chambers or extensive melt segregation and mixing in the upper mantle have homogenized the isotopic systems, and this in turn, enhances the possibility of exposing and resolving fine-scale mantle heterogeneity

All analyses were performed on glass samples to minimize the problem of seawater contamination After separation by hand picking, the glasses were washed in acetone and leached in 6 2 HCl Sr and Nd were isolated by ion exchange following the techniques of Hart and Brooks[8] and Richard *et al*[9] respectively All samples were analysed on a modified, automated NBS 12-inch mass spectrometer at the Université de Montréal Nd and Sm were analysed on a double Ta–Re filament arrangement, whilst all other elements were run on a single Ta filament The data for the glass samples plus Sm, Nd and ^{143}Nd/^{144}Nd data for the rock standard BCR-1 and Nd oxide JMC-321 are given in Table 1 The sample identification conforms to the usual Woods Hole Oceanographic Institution's designation where G104-25-1 indicates sample number 1 from station 25 of RV Gilles Cruise 104

When all the data from 22°–24° are considered, the compositions fall at the low ^{87}Sr/^{86}Sr and high ^{143}Nd/^{144}Nd end of the Sr–Nd correlation[1 2 9–11] and extend the range for oceanic basalts to the most depleted values yet reported from the sea floor Figure 2 shows that the fracture zone clearly marks a barrier to isotopic domains The compositions of the samples from the ridge axis and from the fracture zone walls from the northern section are isotopically distinct from those of the southern section. The range in variation in ^{143}Nd/^{144}Nd isotopic composition exceeds that of ^{87}Sr/^{86}Sr, resulting in a vertical distribution across the oceanic trend similar to that observed for Iceland[12] and for the Marianas[13]

The abundances of the most lithophile elements show

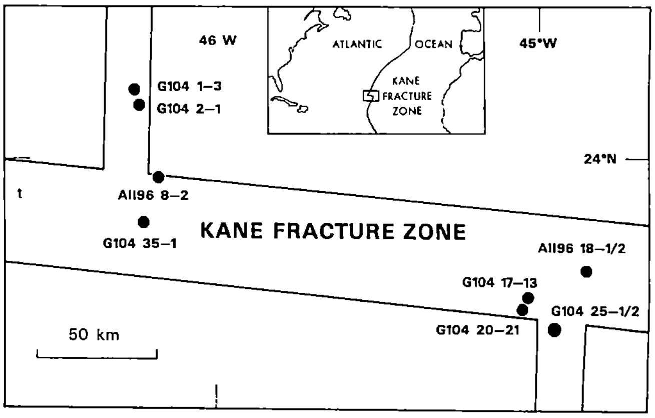

Fig. 1 Sample location map for the Kane Fracture Zone

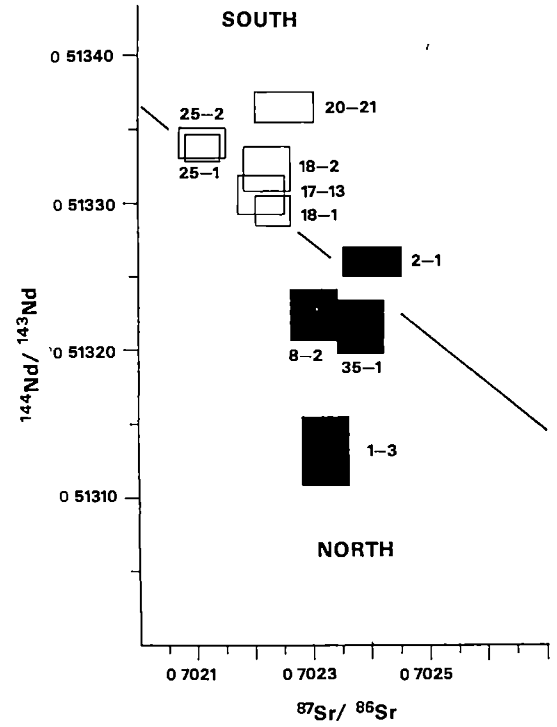

Fig. 2 ^{143}Nd/^{144}Sr and ^{87}Sr/^{86}Sr data for the Kane Fracture Zone basalt glasses (open symbols, southern intersection, solid symbols, northern intersection)

considerable variation both within a ridge section and between the northern and southern sections K/Rb varies from 1,250 to 1,820 in the southern ridge section relative to a variation of 680–760 in the northern section, whilst K/Ba values are of the order of 165 and 65 respectively Both K/Rb and K/Ba exhibit an inverse correlation with ^{87}Sr/^{86}Sr Although there is some overlap between the northern and southern sections, the samples define a positive correlation on the Rb/Sr isochron diagram (Fig 3*a*) which if interpreted as an age corresponds to 805 Myr (with an ^{87}Sr/^{86}Sr $R_{\rm i}$ = 0 70205). In contrast, the samples have similar Sm/Nd in both data sets with the exception of sample G104-2-1 which has a higher ratio This sample and others from this site are anomalous in having high Sr abundance relative to those samples from the northern section (Fig 3*c*)

The most significant geochemical property of the glass samples is their extreme trace element depletion in the southern section (as manifest in K/Rb, K/Ba and Rb/Sr ratios), and the correlation of that depletion with isotopic depletion Possible mechanisms by which these data can be explained include (1) long-lived mantle heterogeneity developed during the evolution of the sub-oceanic mantle, (2) a recent mixing event involving an enriched component added to and mixed incompletely with the oceanic mantle (such as a plume source and lateral transfer away from the plume), (3) transfer of volatile elements from the lower to the upper mantle

The geographical constraints, in which the samples from the northern section are enriched relative to those from the southern section are fundamental in appraising these models For instance, we see no plausible mechanism by which a superficial (lithospheric) structure such as a transform fault could control the observed distribution in isotopic ratios that would arise during voltaile transfer of variably enriched fluids from the lower to the upper mantle Such geographical control requires either a lateral transfer of relatively enriched material in the upper mantle, or mantle heterogeneity developed before or during the initial opening of the Atlantic Ocean The fracture zone is thus controlling or is controlled by the heterogeneity

Two lines of isotopic evidence can be used to support a mixing model First, samples from the northern section are more radiogenic than those from the southern section and may thus represent mixing of enriched and depleted material along a N–S axis Second, there are correlations defined by the samples from the southern section (Fig 3*c*, *d*), which on first examination could be interpreted as mixing lines Bryan *et al*[5] cite trace element data that support magma mixing over limited regions for the southern section However, data such as K/Rb, which confirm the more enriched character of the mantle in the northern section, are inconsistent with a simple mixing model For instance, K/Rb for site 20 is higher than that in the more depleted samples of site 17 When the 1/Sr and 1/Nd diagrams

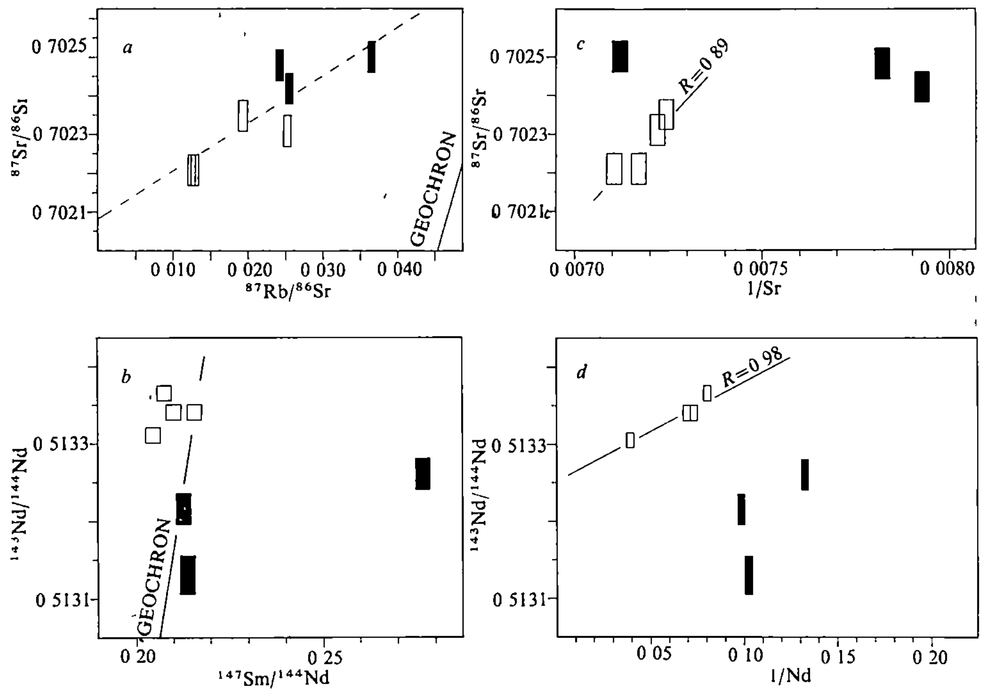

Fig. 3 *a*, Rb–Sr isocron diagram, *b*, Sm–Nd isochron diagram, *c*, $^{87}Sr/^{86}Sr$ against 1/Sr, and *d*, $^{143}Nd/^{144}Nd$ against 1/Nd for the Kane Fracture Zone basalt glasses

are compared they reveal similar inconsistencies For example, one of the end members of the southern section on the 1/Sr diagram plots between the end members on the 1/Nd diagram Although there is no positive confirmation of mixing based on the isotopic data, we cannot discount the possibility that on a small scale (that is between adjacent sites or within a single site, see ref 5) mixing may have occurred

The isochron diagrams (Fig 3*a*, *b*) reveal that whilst the samples define a 'reasonable' age on the Rb/Sr isochron plot, they define ages older than Earth on the Sm/Nd diagram This decoupling of parent–daughter isotopes in the Sm/Nd system is interpreted to be a result of recent petrogenetic processes involving garnet and clinopyroxene[14] Despite these complications, which, for example, result in a vertical distribution on the Sm/Nd isochron plot, we distinguish three subsets on the Sr/Nd correlation diagram (Fig 2) and the Rb/Sr isochron diagram (site 25, sites 1, 2, 8, 35 and sites 17, 18, 20) These subsets may reflect heterogeneities that developed during either a single event[15] or an extended period of mantle differentiation[16] However, the correlation of these subsets on the Rb/Sr isochron diagram implies that, even on a small scale, the mantle has remained heterogeneous over a considerable period

Trace element data for the MAR between the Kane Fracture Zone and 37° N (ref 17) indicate that major transforms such as the Hayes Fracture Zone delineate mantle regimes No isotopic data are available for the MAR between the Kane Fracture Zone and the FAMOUS region (36° N) and we cannot evaluate isotopic heterogeneity across the Hayes transform However, due to the lack of simple mixing relationships between the northern and southern sections of the MAR at the Kane Fracture Zone we speculate that, in some cases, a transform may act as a barrier to different mantle domains Support for this model comes from $^{87}Sr/^{86}Sr$ data for the Gibbs Fracture Zone[4] for which the values vary from $\simeq 0\ 70285$ in the northern section (60°–53° N) to 0 70225 in the southern section (53°–49° N) Furthermore, White and Schilling[4] indicate a sharp increase in $^{87}Sr/^{86}Sr$ initial in the region 49°–43° N which supports our contention that lateral flow away from an enriched mantle source is limited geographically Thus it seems that individual ridge segments bounded by transforms, could sample isolated mantle domains

The recognition of mantle heterogeneity over a limited region of the MAR characterized by 'normal MORB' places constraints on the scale of the heterogeneities and the extent of melt segregation in a convecting mantle Allègre *et al*[16] recognized that the oceanic mantle is heterogeneous on the mineralogical scale and Zindler *et al*[18] identified long-lived mantle heterogeneity on a kilometre scale Our data reveal that the mantle source for MAR is heterogeneous on a scale of tens of kilometres Magma batches of a similar major and trace element geochemistry may thus be characterized by significantly different isotopic ratios. However, our data and other published data[1–4] suggest that this mantle source is heterogeneous on the scale of tens to hundreds of kilometres, and that portions of the MAR are sampling long-lived heterogeneities that predate or coincide with the opening of the Atlantic Ocean Evidence from the Kane Fracture Zone and other Atlantic Ocean fracture zones indicate that these domains may be segmented by major transforms

The existence of isotopic heterogeneities in oceanic basalt glasses from adjacent sites implies that large scale magma chambers and regions of melt segregation do not exist in the upper mantle below the Kane Fracture Zone We envisage that melting, in a convecting upper mantle, results in the separation of liquid from discrete pods and hence basalts from adjacent sites may display totally different pre-eruptive histories

Fluid evolution and graphite genesis in the deep continental crust

William Glassley

Department of Geology, Middlebury College, Middlebury, Vermont 05753, USA

Metamorphism in deep continental crust is often accompanied by carbon-rich, H_2O-poor fluids[1–5], and is characterized by the development of granulite facies mineral assemblages[3–5]. Graphite, a minor phase in many high-grade metamorphic rocks[6–17], has also been recognized in recent xenoliths of deep crustal material[18], demonstrating its presence in modern deep continental crust. Although graphite is most common in biotite schists, it has also been recorded in pyroxene gneisses, two feldspar-quartz pegmatites, marbles and quartzo-feldspathic gneisses[11,15–19]. The presence of supracrustal sequences in granulite facies regions[6–19] suggests that the latter developed through progressive metamorphism and dehydration of shallow level crustal material. Much of this material must have experienced a metamorphic recrystallization in the amphibolite facies, accompanied by the development of hornblende. Although graphite in the high-grade rock may develop from oxidation of organic material, this may not be the most common means for graphite genesis. In much of West Greenland[14] and in southern Norway[12] the low-grade, hornblende-bearing material does not contain significant quantities of organic compounds, although graphite is found in higher-grade metamorphic equivalents. This strongly suggests that introducing CO_2 into deep crustal material leads to fluid evolution and graphite formation. I outline here the evolution of fluid composition in the C–O–H system which is in equilibrium with common crustal mineral assemblages. Thermodynamic data for CO_2–H_2O mixtures[20] and mineral components[21] are used to model the chemical changes in fluid composition which accompany introduction of CO_2 into various types of rock. The results demonstrate that graphite genesis is a direct consequence of deep crustal metamorphism in the presence of a CO_2-rich fluid phase. In addition, the calculations demonstrate that the deep continental crust will not be a reservoir for large volumes of methane-rich gas.

Although the behaviour of fluids in deep continental crust is unknown, fluid inclusion studies imply that carbon-rich fluids may migrate through the crust over large distances (tens of kilometres)[4] Here it is assumed that the fluid migration is accompanied by mixing of introduced CO_2 with *in situ* H_2O Continuous addition (flow) of CO_2 ultimately removes H_2O from the deep crust Thus, H_2O and CO_2 only mix along a migrating front of CO_2-rich fluid Below I examine fluid and mineral behaviour as this front migrates through biotite–magnetite–potassium feldspar (BMK) rocks

Rocks at deep crustal levels experience temperatures >600 °C and pressures >7 kbar In such conditions rocks are unlikely to possess any significant intrinsic pore space Consequently, introduced or *in situ* fluids create pore space sufficient for their volume Thus, fluid pressures are considered equal to lithostatic pressures, and no volume constraints are placed on the fluid

Thermodynamic properties of CO_2–H_2O mixtures were calculated from a modified Redlich-Kwong equation of state (MRK)[20] For the pure gases the derived fugacity coefficients are similar to those derived by Flowers[22], but differ substantially from those presented by Ryzhenko and Volkov[23] H_2, O_2, CO and CH_4 fugacity coefficients were obtained from ref 23

Calculations were carried out to determine in what fluid compositions the BMK assemblage would be stable These compositions were then compared with those for which graphite is stable This comparison determines whether graphite formation could result as a C–O–H fluid evolves in the presence of BMK

The BMK assemblage was considered because it is common in granulite facies rocks This assemblage defines hydrogen fugacity (f_{H_2}) through the equilibrium

$$\underset{\text{Annite}}{KFe_3AlSi_3O_{10}(OH)_2} = \underset{\text{Magnetite}}{Fe_3O_4} + \underset{\text{K-spar}}{KAlSi_3O_8} + H_2 \qquad (1)$$

The equilibrium constant for equation (1) (K_1), derived from the thermodynamic data and SUPCRT computer program of Helgeson *et al*[21], yields

$$\log f_{H_2} = \log\left(\frac{a^{bi}_{ann}}{a^{sp}_{mag}\ a^{feld}_{K\text{-spar}}}\right) - 21\ 68 + 8\ 176 \log (T\ °C) \qquad (2)$$

where a^j_i is the activity of i in phase j (bi, biotite, ann, annite, sp, spinel, mag, magnetite, K-spar, potassium feldspar, feld, alkali feldspar)

Equation (2) was derived by fitting a logarithmic function to log k_1 values which had been calculated at specified pressures and temperatures along chosen geothermal gradients The small volume change of equation (1) at pressures >5 kbar and temperatures >500 °C ($\Delta V_s < 0\ 88$ cm^3) means that no pressure terms are needed in equation (2)

Solution of

$$H_2 + \tfrac{1}{2}O_2 = H_2O \qquad (3)$$

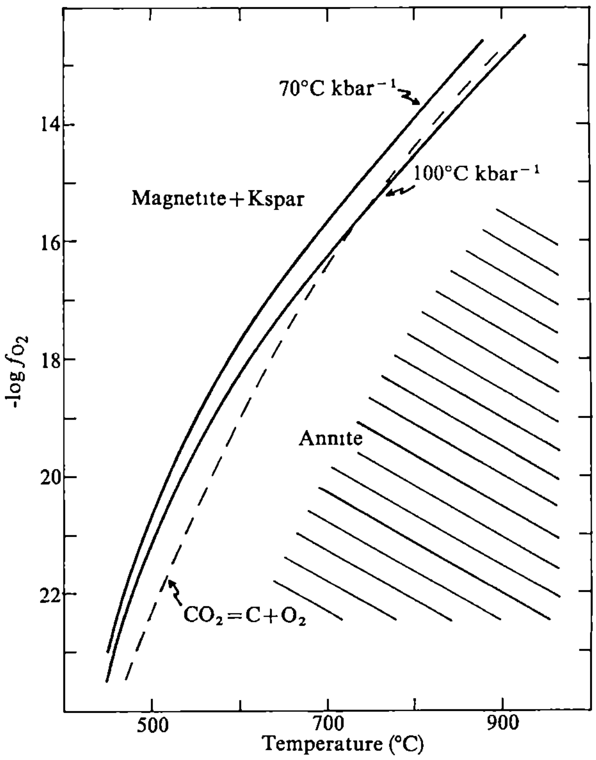

Fig. 1 Log f_{O_2} plotted against T for the BMK assemblage at geothermal gradients of 70 °C kbar^{-1} and 100 °C kbar^{-1} Note the small pressure effect implicit in the curve location The solid curves represent the case where $X_{H_2O} = 1\ 0$ and $X^{bi}_{ann} = 1\ 0$ The graphite–oxygen–carbon dioxide buffer curve is shown for reference (100 °C kbar^{-1}, $P_f = P_{CO_2}$) The ruled region shows the CH_4-dominated portion of the plane where $P_f = P_{CO_2} + P_{H_2O} + P_{CO} + P_{H_2} + P_{O_2} + P_{CH_4}$

0028–0836/82/030229—03\$01 00

allows calculation of f_{O_2} in a BMK assemblage at a specified P, T (degrees kelvin) and X_{H_2O} Solving log k_3 for log f_{O_2}, and substituting equation (2) for log f_{H_2} results in

$$\log f_{O_2} = 2\Big[\log (X_{H_2O}\cdot \gamma_{H_2O}\ P_f) + 21\ 20 - 8\ 176 \log (T-273)$$

$$-\left(\log \frac{a^{bi}_{ann}}{a^{sp}_{mag}\cdot a^{feld}_{K\text{-}spar}}\right) - \frac{12{,}510}{T\ \mathrm{K}} + 0\ 979 \log (T)\Big] \qquad (4)$$

X_{H_2O} is the mole fraction of H_2O in the fluid phase, γ_{H_2O} is the H_2O fugacity coefficient and P_f is the fluid pressure Equation (4) allows f_{O_2} to be calculated in the presence of a fluid of variable composition which is dominated by H_2O and CO_2

$$C + O_2 = CO_2 \qquad (5)$$

allows calculation of f_{O_2} in the presence of graphite at a specified X_{CO_2} Comparison of f_{O_2} values derived from equations (4) and (5), as a function of X_{H_2O}, provides a basis for outlining fluid evolution, graphite genesis and phase composition changes in the BMK assemblage

All calculations were carried out along geothermal gradients For comparison the results for the 100 °C kbar^{-1} and 70 °C kbar^{-1} geotherms are presented.

In the log $f_{O_2} - T^*$ plane, equation (1) exhibits a positive slope similar to that of other oxygen buffers (Fig 1) (Note that T^* represents specified pressure as well as temperature since all calculations are carried out along defined geothermal gradients.) However, the BMK assemblage is not an oxygen buffer because the solid and fluid phases are solutions, the location of the curve in the plane is specified only because the geothermal gradient and phase compositions are specified

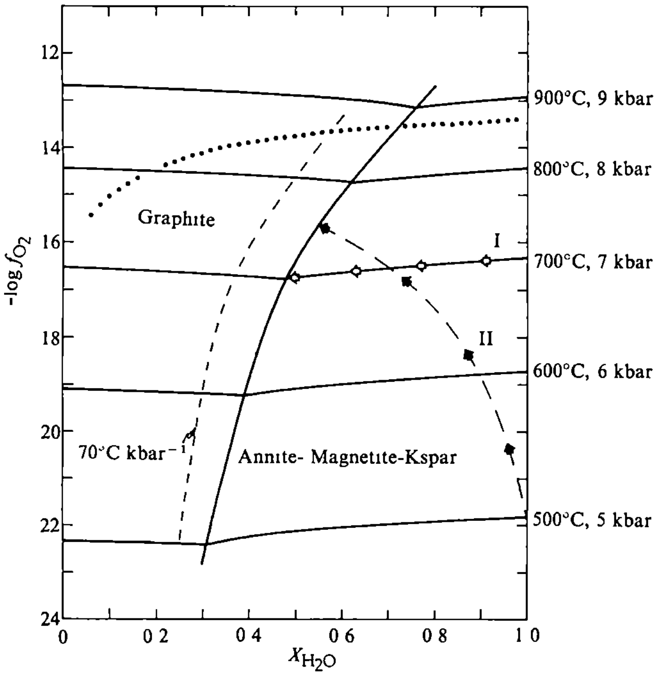

Fig. 2 Projection of BMK–fluid and graphite–fluid surfaces onto the log f_{O_2}/X_{H_2O} plane, from log f_{O_2}–X_{H_2O}–T^* space The solid lines labelled in P and T are contours on the two surfaces (100 °C kbar^{-1}), the intersection of the surfaces being represented by the solid line which cuts the contours at a high angle The intersection at a geothermal gradient of 70 °C kbar^{-1} is shown by the labelled dashed line These contours and intersection are drawn for the case where $X^{bi}_{ann} = 1\ 0$ and assumes $X_{H_2O} + X_{CO_2} \cong 1\ 0$ The effect of lowered iron concentration in the mica is shown by the dotted line, which represents the contour for 700 °C, 7 kbar, $X^{bi}_{ann} = 0\ 3$ Metamorphic pathways (I) (open arrows) and (II) (solid arrows) are discussed in the text

In log f_{O_2}–X_{H_2O}–T^* space, two surfaces can be drawn which represent the temperature-dependent, equilibrium fluid compositions for equations (1) and (5) Figure 2 shows these surfaces projected on to the log f_{O_2}–X_{H_2O} plane, and contoured for T^* In this projection, the isothermic contours for the BMK surface trend to lower log f_{O_2} values as X_{H_2O} decreases In contrast, the isothermic contours for the surface for equation (5) are at high log f_{O_2} values at low X_{H_2O}, and trend to low log f_{O_2} values at high X_{H_2O} Because of the contrast in curvature, these fluid composition surfaces intersect to form a low log f_{O_2} trough in the log f_{O_2}–X_{H_2O}–T^* space, which is represented in Fig 2 by the steeply sloping line To the right of the intersection, the contoured surface represents the fluid composition in equilibrium with BMK assemblages lacking graphite, to the left of the intersection the surface represents the fluid composition in equilibrium with graphite–magnetite–potassium feldspar The assemblage annite–magnetite–graphite–potassium feldspar can occur only along the intersection

Additional components in the biotite will diminish annite activity and the BMK surface (Fig 2) to higher log f_{O_2} values, and will displace the intersection to lower X_{H_2O} values For an $X_{ann} = 0\ 3$, intersection of the surfaces occurs at X_{H_2O} of $<0\ 1$, at 700 °C, where X_{ann} was computed assuming $a^{bi}_{ann} = (X^{bi}_{Fe})^3$, after Wones[24] Addition of other components to magnetite and potassium feldspar shifts the BMK surface such that the intersection occurs at higher X_{H_2O}

Two metamorphic pathways are possible in BMK-bearing deep crustal rocks into which CO_2 is being introduced In the treatment below it is assumed that a geothermal gradient of 100 °C kbar^{-1} is present.

In case (I), CO_2 introduction takes place in isothermal and isobaric conditions If the mica is pure annite, the log f_{O_2}–X_{H_2O} pathway will be that indicated by the open arrows in Fig 2 As CO_2 is added to the system the modal abundance of mica will decrease, as will the oxygen fugacity, until the intersection trough is attained At this point, graphite will precipitate from the fluid and annite will continue to react out until it has been eliminated from the assemblage. Once annite is removed, migration of the fluid composition along the isotherm will resume, increasing log f_{O_2} and X_{CO_2} until all H_2O is removed from the fluid

Case (I) will be complicated if the mica is a mixed annite–phlogopite phase. then the mica composition and its modal abundance become critical equilibrium parameters As CO_2 is added to the fluid the annite component in the mica reacts through equation (1), thus decreasing the activity of annite in the mica As a result, the log f_{O_2}–X_{H_2O} pathway may differ substantially from the pure annite case as the BMK isotherms migrate to higher log f_{O_2} values as the activity of annite in the mica drops (Fig 2) If the number of moles of annite per unit volume is small relative to the number of moles of CO_2 introduced at a given X_{CO_2}, the intersection of the two surfaces will rapidly migrate to very low X_{H_2O} values In such conditions, graphite will probably not precipitate as the annite component will be removed from the mica before the fluid composition reaches the intersection trough Such a system will have a phlogopite-rich mica coexisting with a CO_2-rich fluid phase If the number of moles of annite per unit volume is large relative to the number of introduced moles of CO_2 (a situation likely to occur when the pore volume is low), fluid evolution will approach that for the pure Fe-system where fluid migration can be traced along isotherms fixed in the log f_{O_2}–X_{H_2O} plane Such a system will necessarily produce graphite coexisting with an Fe–Mg biotite

Metamorphic pathway (II) considers the case in which CO_2 is introduced during increasing P and T This case, for the pure Fe-system, is depicted by the dashed, solid-arrowed pathway in

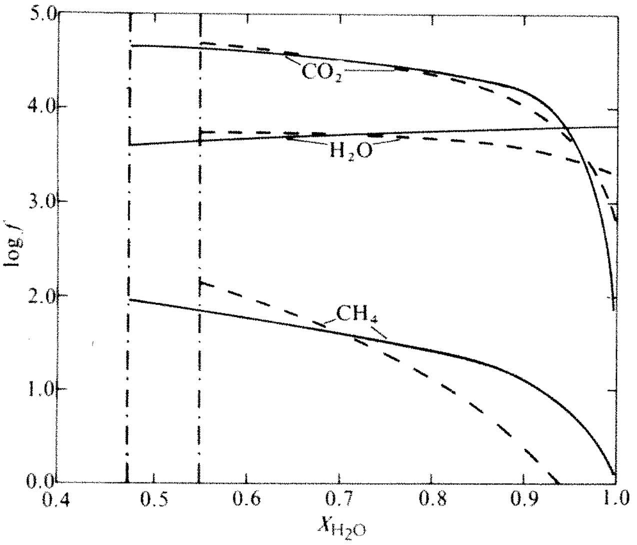

Fig. 3 Fluid evolution along metamorphic pathways (I) (isothermal, solid line) and (II) (polythermal, dashed line). Only H_2O, CO_2 and CH_4 are shown. O_2 can be deduced from Fig. 2; CO is slightly more abundant than CH_4, H_2 slightly less abundant than CH_4 along both pathways. The vertical dash-dot lines mark the point of graphite precipitation from the fluid phase. Both pathways are calculated along the 100 °C kbar^{-1} geotherm, and are represented in Fig. 2.

Fig. 2. For a mixed Fe–Mg biotite the pathway would be much steeper than that depicted, as annite would be progressively removed from mica and the BMK surface would migrate to higher log f_{O_2} values. Whether or not graphite is produced in the Fe–Mg system would again depend on the relative volumes of annite and introduced CO_2.

A comparison of the fluid species fugacities for these two metamorphic pathways (Fig. 3) demonstrates that in both cases a very rapid rise in f_{CO_2} occurs over an X_{H_2O} range of 1.0–0.90. Methane, in both cases, also shows a significant rise, but it never becomes a dominant fluid species. However, the behaviour of H_2O and O_2 are dramatically different for the two cases. In case (I) both these fluid species exhibit a small but significant decrease in fugacity values before graphite precipitation. In case (II), however, both fluid species significantly increase their fugacity values as CO_2 introduction proceeds. In case (I), the H_2O behaviour will lead to progressive dessication of the enclosing rock as dehydration reactions occur in response to the lowering of f_{H_2O}. In case (II), increasing f_{O_2} may result in noticeable oxidation of the mineral assemblage. Solid-phase compositions will change in response to this increase in f_{O_2} through continuous reactions. The exact nature of the phase composition changes will be a function of the appropriate exchange equilibria at *P* and *T*, and can be evaluated from the log *K* expressions for the equilibria.

The BMK-graphite assemblage is not a fluid buffer because biotite composition changes in response to changes in fluid composition. Nevertheless, the assemblage forces fluid composition to lie along the C–CO_2–O_2 surface, placing severe constraints on fluid abundances, at *P* and *T*. If mineral compositions are known, fluid species abundances can be precisely determined. In typical deep crustal conditions (700 °C, 7 kbar), the maximum possible X_{H_2O} is 0.46 for the pure Fe system, although typical mineral compositions (for example, $X^{\text{bi}}_{\text{ann}} < 0.3$, $a^{\text{feld}}_{\text{Kspar}} > 0.7$, $a^{\text{sp}}_{\text{mag}} > 0.7$) allow a maximum X_{H_2O} of 0.15. Log f_{O_2} values are tightly constrained as they must fall on the C–CO_2–O_2 surface which exhibits little variation in log f_{O_2} at a specified *P* and *T*. If either biotite or graphite is missing from an assemblage, fluid composition cannot be quantitatively determined. However, the possible f_{O_2} and X_{H_2O} values can be restricted to specific ranges, at *P* and *T* and specified mineral compositions, because these values must lie along the appropriate isotherm on either the C–CO_2–O_2 surface (biotite absent) or on the BMK surface (graphite absent).

None of the explanations proposed for the genesis of abiotic graphite for a wide range of occurrences[8,25–31] provides a means to develop graphite as a direct consequence of deep crustal metamorphism. The process outlined here, however, demonstrates that graphite will commonly develop in deep crustal settings as a result of CO_2 addition to mineral assemblages in which one of the O–H system fluid species fugacities is mineralogically controlled.

Biotic and abiotic graphite can be distinguished unambiguously by field criteria. In a terrain which has experienced a regional metamorphic event the presence of graphite in high-grade rocks, and the absence of carbon-bearing phases in lower-grade equivalents, for example, in southern Norway[12], is unequivocal evidence for an abiotic origin for the graphite.

The fluid evolution to be expected in such a setting (Fig. 3) is characterized by a very rapid rise in f_{CO_2}. Methane exhibits an increase in abundance, but never becomes a dominant fluid species, in the conditions examined here. Such considerations disprove suggestions[32,33] that intermediate or deep-level continental crust may act as large reservoirs for methane-rich gases.

Although the fluid evolution outlined here relied on the features of only the BMK assemblage, similar observations can be expected from any mineral assemblage which specifies fugacity of a fluid species in the O–H system. Thus, most assemblages containing hydroxyl-bearing minerals and oxides will lead to graphite genesis, provided that the stability limits for these minerals are not exceeded at the X_{H_2O} values compatible with graphite. The particular phase compositions which will be stable with graphite will depend on the geothermal gradient and the modal abundance of the solid phases, as well as on the total fluid volume affecting the rock.

The research reported here was supported by NSF grant DPP-7823305, while I was on leave at the University of California, Berkeley. I thank David Bridgwater, Richard Sack, Kai Sørensen and John K. Winter for helpful discussions, and R. Sack, J. R. Holloway and V. J. Wall for helpful comments and reviews.

New hominoid skull material from the Miocene of Pakistan

David Pilbeam

Peabody Museum, Harvard University, Cambridge,
Massachusetts 02138, USA

Neogene hominoid cranial material is regrettably scarce, especially from the middle and late Miocene. Between the 18-Myr-old virtually complete early Miocene *Proconsul africanus* skull from Rusinga[1] and the 3–4-Myr-old Hadar hominoid cranial material[2], the only significant large (non-hylobatid) hominoid facial or cranial specimens are those from the late Miocene Salonika in Greece[3], Yassiören in Turkey[4], Lufeng in China[5], the possibly middle Miocene site of Moroto in Uganda[6] and the new facial-mandibular piece from late Miocene deposits in Pakistan reported here. The specimen is a *Sivapithecus indicus*[7] adult, probably male, and consists of most of the left side of the face including a small portion of the frontal bone, the zygomatic arch and temporo-mandibular joint, the maxilla, a virtually entire mandible and the complete dentition. The fossil, catalogued as GSP 15000, is the property of the Government of Pakistan and is at present on loan for study at Harvard University.

The face was found during the 1979–80 field season of the Geological Survey of Pakistan–Harvard (then Yale) Peabody Museum Siwalik (GSP-HPM) research project on the Neogene of the Potwar Plateau of Pakistan (co-directed by Dr S. M. Ibrahim Shah and myself). The fossil was discovered by Mark Solomon and Dr John Barry and prepared at Yale by Horace French and Rizwana Raza. It comes from GSP-HPM locality 410 near the village of Kaulial in the Potwar Plateau[8]. Locality 410 is in the Dhok Pathan Formation[9], the locality itself being composed predominantly of red silts, representing overbank deposits[10]. The partial skull was probably not transported far after the animal's death, and was probably scavenged after death. The only other directly associated fossils are a few small mammals—murids, a flying squirrel and a dormouse. However, we have an abundant mammal fauna from many localities at the same stratigraphic level as the face, the so-called U sandstone level, after a prominent marker horizon[8].

	Length	est.	60.0

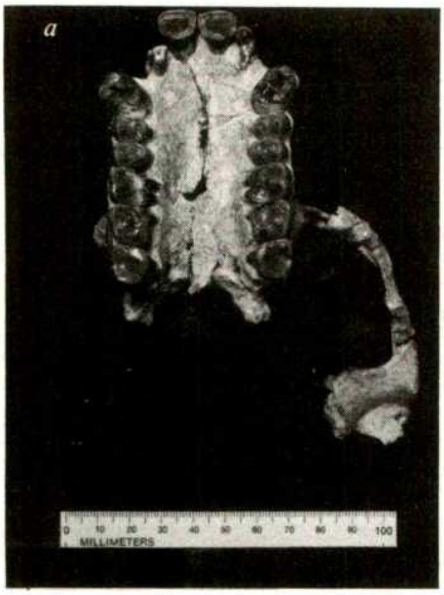
For definitions of parameters measured, see refs 4, 6, 17.

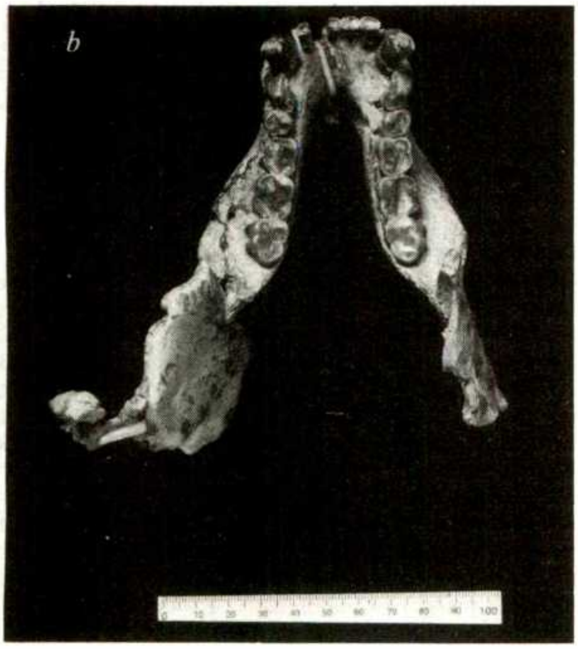
The U level is ~8 Myr old, based mainly on magnetostratigraphic correlations[11,12]. A brief period representing perhaps less than 0.1 Myr has been sampled intensively at that level[13]. No significant plant remains are known, but we have tentatively reconstructed palaeography, habitats and faunal communities by a variety of geological and faunal techniques[8,10,13]. The late Miocene sediments were laid down by two major aggrading river systems, with many associated smaller streams, in an area of predominantly low relief. The habitat was probably a complex mosaic of forest, woodland and grassland, probably with a rich shrub layer. This would explain the abundance of browsing mammals, along with grazers, in the community[8,14].

Sivapithecus indicus is well represented at the U level by jaws and teeth, and a few unassociated postcranial elements probably also represent the same species[7]. If these assignments are correct the species was approximately chimpanzee-sized and more hominoid-like than cercopithecoid-like in overall anatomy; it was probably predominantly arboreal.

The new specimen is unusually complete for this range of time, comprising an upper face, palate, and mandible with a complete adult dentition (Figs 1, 2)[15]. The maxilla above the palate is preserved bilaterally and completely outlines the nasal aperture. Most of the remainder of the right side of the face is missing, except for the base of the malar process and a wedge of nasal process extending almost up to the frontal bone. In the midline and on the left side of the face, the specimen includes the nasal bones, almost complete orbital margin including the lower portion of the frontal bone, and the lateral edge of the face marking the anterior border of the temporalis muscle. The zygomatic bone is well preserved on the left and articulates with a segment of the zygomatic process of the temporal bone. A large fragment is missing from the midface on the left in the area of the zygomatico-maxillary suture. A separate fragment of the left temporal bone includes a complete articular fossa with a prominent postglenoid process. The lateral extent of the articular fossa is complete while medially the piece ends just beyond the articular surface. The mandibular corpus is bilaterally preserved back to the third molars, with a buccinator line well preserved on the right but mostly missing on the left. The specimen is broken and somewhat crushed on the left of the midline. Most of the left ramus is present, including a fragment of condyle, and the right ramus is also relatively complete.

0028-0836/82/030232—03$01.00





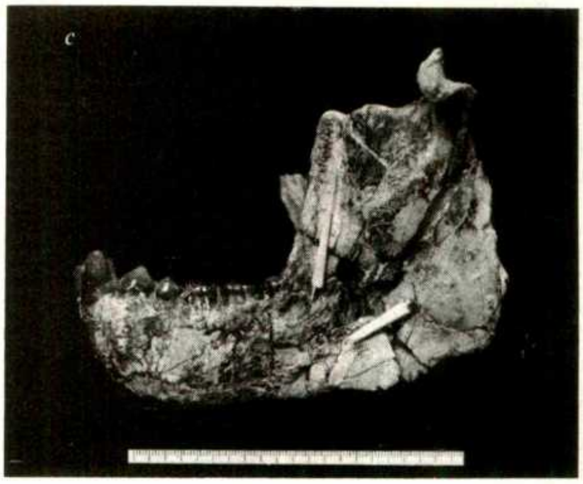


Fig. 2 *a*, Palatal view of GSP 15000; *b*, occlusal mandibular view of GSP 1500; *c*, lateral mandibular view of GSP 15000.

The overall impression is of a delicate face combined with robust jaws and teeth (see Table 1 for measurements). The face is deep from frontal to tooth row and concave in profile. The supraorbital tori are small and the frontal profile steep; there is no frontal sinus. The orbits are ovoid, with their longest dimension vertical, and are separated by a narrow interorbital region. The midfacial length from orbit to nose is greater than that in *Pan* or *Pongo*. The premaxillary region is prow-like and curved, and the incisors quite strongly procumbent. The zygomatic is gracile, and the temporo-mandibular joint shallow and crescentic, with the convexity facing anteriorly; it is ape-like, and similar to that of *Pongo*. The mandible is robust and deep, with well developed posterior symphyseal buttressing; the rami are high and vertical to the corpus.

Table 2 gives dental measurements of GSP 15000. Judging from canine size this is a male. Overall wear on the dentition is very heavy and most occlusal detail is therefore lost; in some cases dentine is extensively exposed. Unworn *Sivapithecus indicus* cheek teeth are high crowned and low cusped, with few occlusal wrinkles, and have thicker enamel than almost all Neogene hominoids with the exception of *Australopithecus*[7]. Wear on the incisors and canines of GSP 15000 is heavy; canines are blunted, and the small upper lateral incisors oddly worn, presumably by occlusion with the lower canines. This suggests extensive anterior tooth use in non-masticatory activity. The maxillary sinus floors descend mostly to the root tips, although posteriorly sinus pockets extend between the roots.

Sufficient frontal bone is preserved and enough known of the position of temporo-mandibular joint and adjacent temporal bone to reconstruct tentatively the anterior half of the brain

For definitions, see ref. 6. Note that all lengths are estimates, and greatly affected by wear.

case. This was hafted high on the face, as in *Pongo* but unlike *Pan*; brain volume was probably in the ape range. In this feature, and in facial profile, jaw joint morphology, malar morphology, orbital shape and disposition, and overall palatal shape, the specimen is quite orang-like. In other features the two species differ; for example, in tooth morphology and wear, and in the considerable fossil midfacial length and ramus height.

Compared with the few other Miocene facial or cranial specimens known, GSP 15000 differs from *Proconsul africanus*[1] and *Proconsul nyanzae*[16] in being more like living pongids, and also differs from the possibly middle Miocene palate and face from Moroto in Uganda[6]. Among other late Miocene hominoids, it is most like the *Sivapithecus* face from Yassiören[4] and less like *Ouranopithecus* from Ravin de la Pluie[3]. However, detailed comparisons with all these specimens, and with those from Lufeng[5] in China and from the Pliocene deposits at Hadar, Ethiopia[2], have not yet been completed.

As reconstruction and analysis of GSP 15000 continues, attention is being paid to the biomechanical meaning and potential functional significance of facial, mandibular and dental features; this involves detailed understanding of equivalent parts in modern systems. As these studies proceed it should be possible to develop a clearer understanding of the significance of the attributes frequently used in taxonomic and phylogenetic analyses. In particular, this will help evaluate the 'primitive' or 'derived' nature of character states.

Meanwhile, there are several similarities between GSP 15000 and *Pongo* that may turn out to be shared derived features. I doubt that *S. indicus* itself is ancestral to *Pongo*; however, I consider it likely that a similar late Miocene species, probably an Asian one, was. To what extent *S. indicus* resembles the last common ancestor of all living pongids and hominids is unclear. There are a few resemblances in mandibular and dental morphology (thick enamel, megadonty, mandibular robusticity) between Pliocene *Australopithecus* and *Sivapithecus* and similar late Miocene species, which may be primitive retentions. If so, in those features at least, the African pongids would be derived rather than primitive, which would have important consequences for the interpretation of hominid origins. However, it would be better to wait until more complete late Miocene hominoid material is recovered, especially from Africa, before constructing evolutionary stories.

This research was supported by NSF grant BNS-8007338 and SFCP grant 908817. I thank Mr Asrarullah the Director General, Geological Survey of Pakistan; all members of the joint project, particularly Ibrahim Shah, Mahmood Raza, Kay Behrensmeyer, John Barry, Catherine Badgley, Horace French and Rizwana Raza; and Richard Smith, Todd Preuss and Steven Ward. Photographs are by William Sacco.

Body temperature changes during the practice of g Tum-mo yoga

Herbert Benson*, John W. Lehmann*,

Since meditative practices are associated with changes that are consistent with decreased activity of the sympathetic nervous system[1–7], it is conceivable that measurable body temperature changes accompany advanced meditative states. With the help of H.H. the Dalai Lama, we have investigated such a possibility on three practitioners of the advanced Tibetan Buddhist meditational practice known as g Tum-mo (heat) yoga living in Upper Dharamsala, India. We report here that in a study performed there in February 1981, we found that these subjects exhibited the capacity to increase the temperature of their fingers and toes by as much as 8.3 °C.

g Tum-mo yoga is a form of meditation which allegedly allows its practitioners to alter body temperature. Previously, only subjective descriptions of this phenomenon existed: "The neophytes sit on the ground, cross-legged and naked. Sheets are dipped in icy water, each man wraps himself in one of them and must dry it on his body. As soon as the sheet has become dry, it is again dipped in the water and placed on the novice's body to be dried as before. The operation goes on in that way until daybreak. Then he who has dried the largest number of sheets is declared the winner of the competition"[8].

During the practice of g Tum-mo yoga, '*prāna*' (literally, 'wind' or 'air') is withdrawn from the scattered condition of normal consciousness and is made to enter into the 'central channel' inside the body. Then, through the alleged dissolution of these winds in the central channel, the 'internal heat' is ignited. The physiological changes are, therefore, a by-product of a religious practice.

Each of the three monks in the present investigation had spent more than 6 years practising g Tum-mo daily and had lived most of the past 10 years in near-isolation in unheated, uninsulated stone huts $\sim 4\times 7$ m. The floors were earthen and the roofs made of large slate slabs or flattened tin cans. The huts were in isolated locales in the foothills of the Himalayan Mountains at altitudes of 1,800–2,800 m, outside the town of Upper Dharamsala. The first two subjects were studied in their hermitages while the third was studied in a hotel room in Upper Dharamsala. Each participated in the investigation after being asked to do so by H. H. the Dalai Lama. Verbal informed consent was obtained from the three subjects through our translator (J.H.).

Skin temperature was measured in the area of the navel and lumbar region, the chest (nipple), left forearm, left fifth finger nailbed, left calf, left fifth toe nailbed and forehead using small disk thermistors (Yellow Springs Instrument Corporation (YSI), model 427) that were attached to the skin with plastic tape. Rectal temperature was monitored by means of a YSI rectal catheter probe inserted 10 cm beyond the anal sphincter. Air temperature was measured by YSI thermistor air probe (model 405) as well as with a conventional sling psychrometer which was used to measure psychrometric wet bulb temperature to calculate relative humidity. All wires were connected to a multichannel (YSI) switch box (model 4002) and connected to a YSI wide-range Telethermometer (model 42) with a 60 °C range. Heart rate was monitored with a San-EI (model 2D16) Pulse-

0028-0836/82/030234—03$01.00

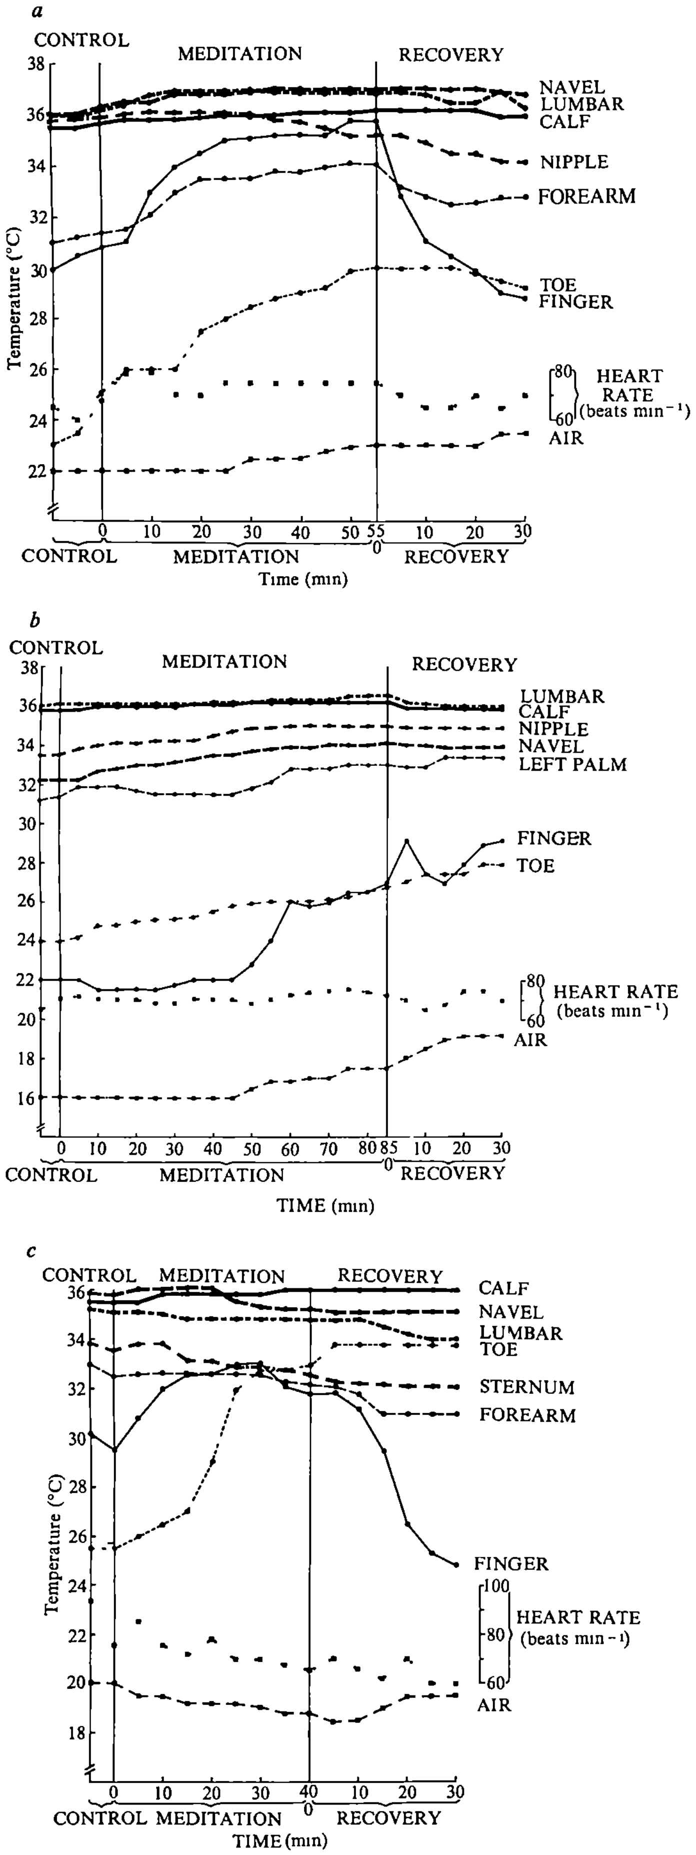

Fig. 1 Skin and air temperature and heart rate changes before, during and after the practice of g Tum-mo meditation in subjects G J (*a*), J T (*b*) and L T (*c*)

meter monitor which used a digital probe to sense each pulse of blood flowing into the thumb Measurements were taken sequentially and tabulated every 5 min during control, meditation and recovery periods

The first subject, Ven G J , aged 59 yr, sat in the cross-legged 'Lotus' posture During a 55-min period of g Tum-mo meditation, his finger temperature increased 5 9 °C and his toe temperature 7 0 °C (Fig 1*a*) In the recovery period, finger temperature returned to baseline levels, while toe temperature, with the toes protected against heat loss by the lotus position, remained elevated Navel and lumbar temperatures increased by 1 °C during the meditative period Rectal temperature was unchanged Air temperature slowly increased from 22 0 to 23 5 °C during the hour Heart rate increased slightly, by 2 beats per min, during the meditative period and then returned to baseline levels

Finger temperature in the second subject, Ven J T , aged 46 yr, increased 7 2 °C, the highest levels being recorded in the recovery period at a time when the subject claimed that, although he had stopped meditating, the subjective experience of g Tum-mo heat had continued (Fig 1*b*) A similar pattern with a 4 0 °C increase was noted in the toe temperature Navel temperature increased 1 9 °C and nipple temperature 1 5 °C Rectal temperature was unchanged Air temperature slowly increased within the hut from 16 °C to 19 2 °C, the most marked changes occurring late in the recovery period Heart rate was essentially unchanged throughout

The third subject, Ven L T , was 50 yr old Because his g Tum-mo changes started any time he was in a sitting posture, baseline measurements were taken in the upright posture We first performed measurements on this subject outside his hut However, high radiant heat temperatures hampered skin temperature measurements and since our visit coincided with the celebration of the Tibetan New Year, when the monk walked to Upper Dharamsala to listen to a lecture given by H H the Dalai Lama, we studied him again in a cool hotel room His finger temperature rose 3 15 °C while toe temperature increased 8 3 °C (Fig 1*c*) There were no other large changes in skin temperature Rectal temperature was unchanged Air temperature within the hotel room decreased during the meditation period from 20 to 18 5 °C, and then rose to 19 5 °C in the recovery period Heart rate decreased after assuming the sitting position and continued to fall slowly throughout the experiment

The subjects in the current experiment exhibited a greater capacity to warm fingers than has been previously recorded during hypnosis and after biofeedback training[9-15] Although it is possible that the practitioners had learned to increase their metabolism to produce more body heat, this seems unlikely Even though they were all lean, the monks claimed not to require more than a 'normal' amount of food Furthermore, their resting heart rates were within normal limits The most likely mechanism to account for the increase in finger and toe temperature is vasodilation Although no direct measurements of peripheral blood flow were made, others have calculated that during the simple meditative process of transcendental meditation, there is a 44% increase in nonhepatic, nonrenal blood flow[16] and they hypothesized an increase in skin or cerebral blood flow or both

We thank H H the Dalai Lama and other members of the Tibetan community of Dharamsala, India, notably Ven Doboom Tulku and Tendzin Choegyal, for their support We also thank Wendy L Wornham, M.D , Irene L Goodale and Nancy E MacKinnon for their assistance This work was supported by grants from the National Science Foundation (NSF INT 8016982), the American Institute of Indian Studies, the National Institutes of Health (HL 22727 and HL 07374), the Fleischmann Foundation and the Fetzer Foundation

Preferences for cousins in Japanese quail

Patrick Bateson

Sub-Department of Animal Behaviour, University of Cambridge, Madingley, Cambridge CB3 8AA, UK

Early experience affects the mating preferences of many birds and mammals[1,2]. The plasticity of behaviour is such that individuals reared with a member of another species may subsequently choose to mate with that species[3–6]. Recent evidence suggests that the most strongly preferred mates are slightly different from individuals that are familiar from early life[7–9]. The implication of these findings is that an individual is able to strike an optimal balance between inbreeding and outbreeding by learning about its immediate kin and mating with a member of the opposite sex that is slightly different from its immediate kin[1,10]. What such a balance might amount to in practice has previously been uncertain. I report here that Japanese quail of both sexes, having been reared with their siblings, subsequently prefer a first cousin of the opposite sex.

The Japanese quail (22 males and 13 females) tested in this experiment were obtained from eggs laid by four different pairs in our laboratory colony. Eggs from a given pair were collected over 2-week periods and placed simultaneously in a separate compartment in an incubator. When transferred 13 days after the start of incubation to a hatching incubator, eggs were again kept in separate families and hatched separately. Within a day of hatching in the dark, the chicks were transferred to rearing pens and kept in true families in the same conditions as those used in previous experiments[7,9]. The birds were isolated 30 days after hatching. Testing started at 60 days, when the quail were sexually mature.

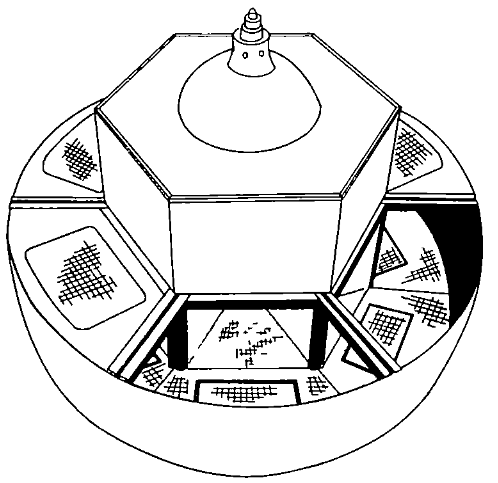

Fig. 1 Apparatus used for testing preferences of adult Japanese quail. Stimulus birds were put singly in the inner compartments, which were painted white and lit from above. The outward-facing windows were fitted with one-way screens. A test bird could move freely round the black unlit outer part of the apparatus. A pedal in front of each window operated a microswitch.

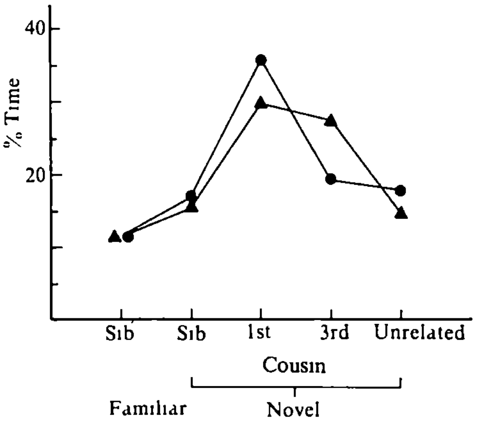

Fig. 2 The mean percentage time spent by adult Japanese quail near members of the opposite sex that were either familiar siblings (Sib), novel siblings, novel first cousins, novel third cousins, or novel unrelated individuals. The chance level is 20%. ▲, Males ($n = 22$), ●, females ($n = 13$).

The pedigrees of the quail in the colony were known for at least four generations and pairings had been carefully arranged. It was possible, therefore, to test all birds with a variety of members of the opposite sex that were of different degrees of relationship but of the same age. In addition, some true siblings were reared separately so that when the birds were tested, they were given choices between familiar and novel siblings, novel first and third cousins, and novel unrelated members of the opposite sex.

The apparatus used for testing the adult quail is shown in Fig. 1. The compartments in which the stimulus birds were placed faced outwards from the centre of the apparatus. The inside walls were painted white and the outside wall consisted of a one-way screen. The outward-facing windows were used so that the test bird was not visible to the stimulus birds. The outer runway was painted black and the test bird could move freely from one window to the next. To eliminate possible bias, when a test bird was initially introduced into the apparatus, it was placed in front of a compartment containing a different stimulus bird from the one tested previously. Furthermore, food and water for the test bird were placed on the outside wall opposite the compartment of every stimulus bird. Each test session lasted 30 min. Pedals which triggered microswitches were placed in front of the compartment of each stimulus bird. The time spent in front of each of these stimulus birds was recorded automatically and expressed as a percentage of the total time spent in front of all five types of stimulus bird.

Figure 2 shows the mean percentage duration spent in front of each category of stimulus bird by both adult males and females. Table 1 gives the scores for each individual. The males were slightly more ready than females to spend time near a third cousin of the opposite sex. However, in this sample at least, the behaviour of the two sexes were statistically indistinguishable and, for the purpose of the analysis, these data were pooled. First, all the data were examined using the Friedman test and the overall deviation from chance was found to be statistically significant ($\chi^2 = 10.07$, $P < 0.05$). Second, the time spent near each category of stimulus bird was compared with the time spent near each other category of stimulus bird using the Wilcoxon matched-pairs test. The time spent near novel first cousins was significantly greater than that spent near both familiar and novel siblings ($z = 3.02$, $P < 0.01$ and $z = 2.23$, $P < 0.05$, respectively). The time spent near novel first cousins was also

significantly greater than the time spent near unrelated individuals ($z = 2.18$, $P < 0.05$).

Of course, remaining near a member of the opposite sex is not the same as attempting to mate with it. However, other experiments have shown that, in adult male Japanese quail, the time spent near a female in a choice test is strongly linked to the copulation preference[7]. Furthermore, the males in the present experiment were observed to court the females in the choice tests. Finally, I have found in other experiments that birds show no consistent preferences for members of the same sex.

Despite the clear overall preference for first cousins, the data were highly variable and only 12 of the 35 birds spent most time near a first cousin (see Table 1). The variability was expected as the degree of relationship between two individuals only indicates the probability that the two share heritable characters. I have confirmed this by direct measurement of the quails' plumage. Although, for example, first cousins are on average more like each other than unrelated individuals, unrelated birds may resemble each other more closely than some first cousins. Knowledge by a bird of a sibling's appearance must necessarily be an imperfect guide to what a first cousin will look like.

The most preferred category of relations will probably depend on the degree of outbreeding of the population[9]. The quail used here were relatively inbred and 'unrelated' birds were physically rather similar to each other. In populations that are physically more variable than our laboratory quail, the most preferred member of the opposite sex might be more closely related than a first cousin. In contrast, the effect of restricted experience in a laboratory experiment might have meant that the birds were more ready to escape from novelty than would be the case for quail growing up in a natural environment. Therefore, in a free-living population, the effects on sexual preferences of greater variation in the plumage of the population may cancel out those of more varied experience.

In many human societies, marriage to a first cousin is common[11]. This apparent similarity between the behaviour of humans and quail should be noted. Humans may strike a balance between the costs of inbreeding and those of outbreeding[10,12] and in doing so, may rely on their early experience in a way similar to quail. Clearly, many factors deriving from culture and individual experience affect human mating preferences, but one influence may well be an attraction towards a member of the opposite sex who differs, but not to a large extent, from well known, closely-related members of the family.

I thank Mr John Owen for assistance in the care and testing of the animals, and Mr Tom Goss and Mr Brian Maltby for building the apparatus. The research was supported by a SERC grant.

Early auditory experience modifies sound localization in barn owls

Eric I. Knudsen, Phyllis F. Knudsen & Steven D. Esterly

Department of Neurobiology, Stanford University School of Medicine, Stanford, California 94305, USA

The auditory system localizes sounds by comparing the timing and intensity of sounds arriving at the two ears, and associating specific binaural differences with directions of sounds in space. Thus, location for the auditory system, like stereoscopic depth for the visual system, is a percept created in the brain by a comparison of inputs from two receivers. We considered whether the neural mechanism underlying sound localization is determined entirely genetically, or if it is modified and regulated by auditory experience. The influence of experience on sound localization has been examined previously in various species, including man, with contradictory results[1-9]. For our study we used the barn owl (*Tyto alba*) as an experimental model because it localizes sounds with extreme accuracy[10,11]. By placing a plug in one ear, we disrupted the owl's binaural localization cues and induced large errors in sound localization. We report here that young owls adjusted to the altered cues and regained normal localization accuracy over a period of weeks. However, as the owls aged, their rate of adjustment slowed, and beyond 6–7 months of age, their capacity to adjust was lost or greatly reduced. This plasticity of the sound localization mechanism early in life thus enables the auditory system to establish precise correlations between binaural cues (which vary between individuals) and directions of sounds in space.

The localization cues used by the barn owl are those used by man—interaural differences in intensity and time[12-14]. However, because of a vertical asymmetry in the positions of the owl's ears, high frequency sounds are loudest in the right ear when they originate above and to the right, and loudest in the left ear when they come from below and to the left[15]. Behavioural and physiological studies demonstrate that owls use interaural intensity cues to localize the elevation of sounds, and both interaural time and intensity cues to localize the azimuth[13,14].

In our experiments, we occluded ears by suturing a foam rubber plug into the auditory canal. The effect of such a plug on the auditory signal was determined in one bird by measuring the sensitivity and phase of cochlear microphonic responses before and after the treatment. The plug attenuated the signal by 30–55 dB from 1 to 10 kHz depending on frequency, and altered the phase of each frequency. Thus, both interaural intensity and timing cues were severely disrupted by this procedure.

The experiments were done in a darkened anechoic chamber with the owl perched in the centre. Sound stimuli were generated by a 4-cm speaker that could be moved to any position around the owl by remote control. Travelling with the speaker and centred in its cone was a 3-mm light bulb that provided a light stimulus. The behavioural paradigm for measuring sound localization error took advantage of a natural head orienting response: on hearing a sound the owl turns its head in a rapid flick or saccade, bringing the source of the sound into a frontal region of maximum spatial acuity for the auditory system[10]. This movement also brings the visual axes of the eyes, which are immobile in their sockets, in line with the target. A normal owl orients its head almost identically to either a sound or a light stimulus. In these experiments, a difference in the orientation of the head to sound as opposed to light was taken as an error in sound localization (Fig 1). The behavioural paradigm simply required the owl to orient its head in response to either the sound or light stimulus, for which it received a food reward. The reward was not contingent on the accuracy of the response, only on its crispness and appropriate latency. To quantify the position of the head, a small mirror was attached to a clip cemented to the skull, and a collimated source of IR light was directed at the bird. The mirror reflected the IR beam onto a grid of 0.5° increments in a horizontal polar coordinate system. The location of the beam on the grid was monitored using a video camera and stored on video tape for subsequent analysis.

The sound target consisted of repetitive noise bursts of variable duration, the light target was a constant dim glow of the bulb. In both cases the stimulus was presented for up to 2 s. If the owl did not respond, the stimulus was turned off, followed by a waiting period of 30 s. Typically, however, the owl responded immediately with a saccadic head movement and sustained fixation. The stimuli were maintained long enough to allow the owl to maximize its accuracy. The coordinates of the head orientation were then recorded, a reward light activated, and a food reward delivered. After every trial the speaker (with light bulb) was moved to a new location. The owl received no feedback regarding the accuracy of its responses during these tests.

Five baby owls were used, four as experimental subjects and one as a control. All were kept in identical holding cages and allowed out daily for training and exercise. The auditory experience they received consisted of self-generated noises when active in their cages, and the sounds in the laboratory when allowed out for exercise. At 4 weeks of age we occluded the left ear of owl 1 and the right ears of owls 2 and 3, the right ear of owl 4 was occluded only at 27 weeks. Owl 5, which served as a control and was never plugged, demonstrated the accuracy and precision that can be expected from a normal owl under our experimental conditions. From four measurements made at 18 weeks of age, the mean error of owl 5 ranged in magnitude from 0.8° to 1.4° in azimuth and from 0.4° to 1.7° in elevation, with respective standard deviations of 1.4–2.3° and 1.3–2.7°. These values are almost identical to the localization accuracies of two adult owls that were studied intensively in previous behavioural experiments, using a different measuring technique[10].

From these results, we defined normal localization accuracy as an error of ≤2° in azimuth and elevation (indicated by broken

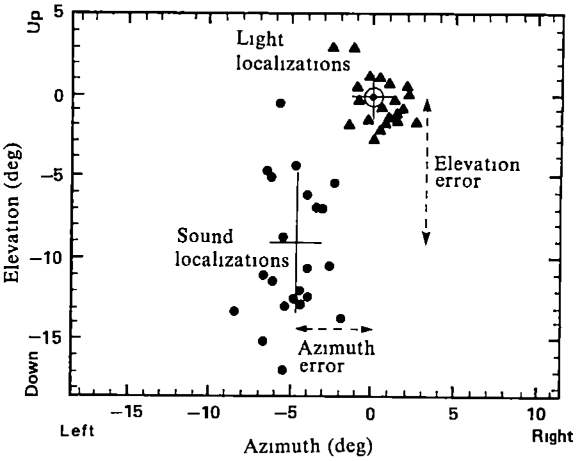

Fig. 1 The distribution of head orientations to sound and light stimuli recorded in a single test session. Each symbol represents a fixation point in response to a sound (●) or light (▲) stimulus. The data were normalized for the location of the stimulus by subtracting the coordinates of the speaker or light bulb from the coordinates of the elicited head orientation. This gave two sets of data points, one for sound and the other for light localizations. The mean and standard deviation of each distribution is indicated by the crossed lines. Sound localization error was defined as the difference in azimuth and elevation of these means. The scatter (standard deviation) of the responses served as a measure of the precision of localization. These data were taken from owl 1 at 120 days old, 1 week after its plug had been removed. In a fully adjusted owl, these point distributions would superimpose almost perfectly.

0028-0836/82/030238—03$01.00

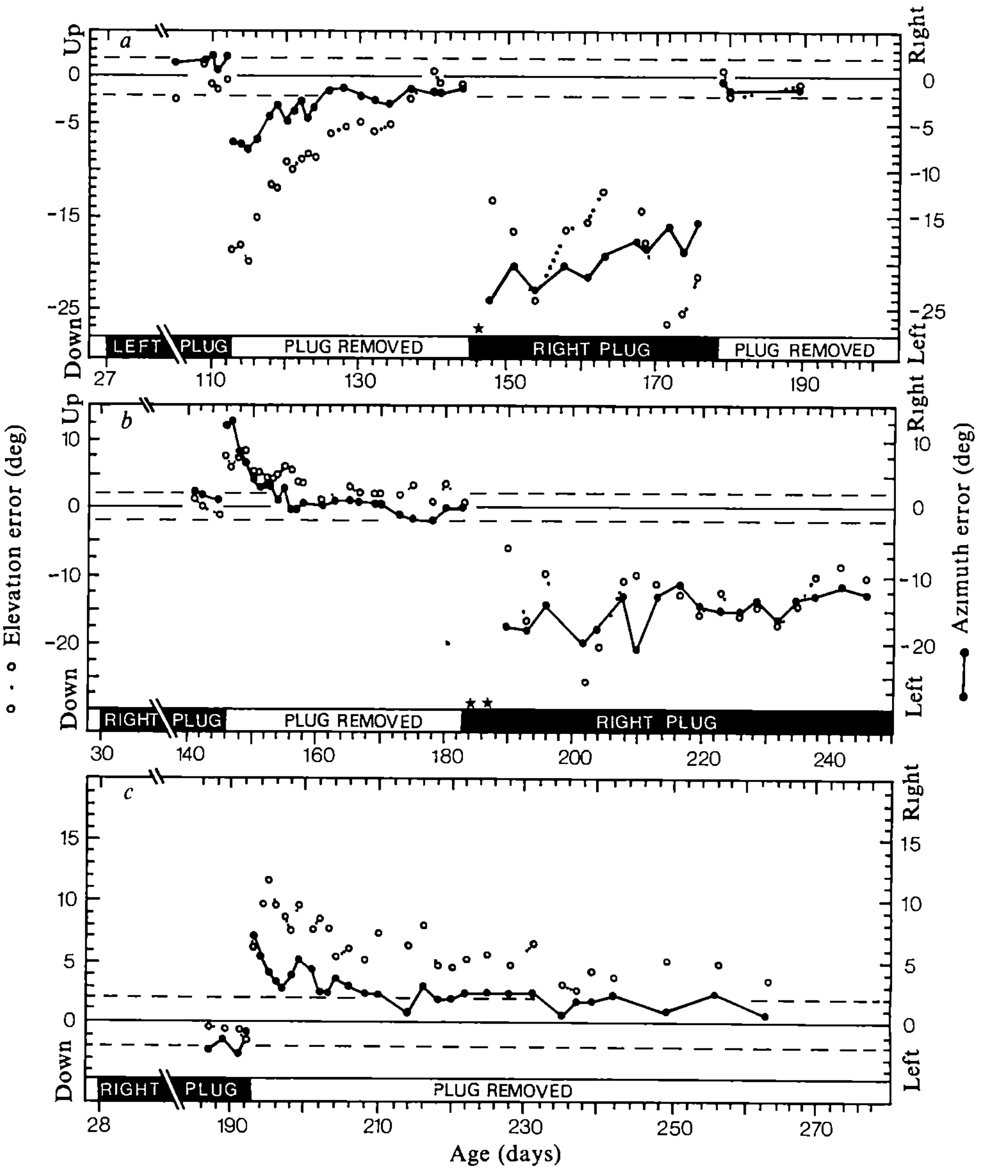

Fig. 2 Adjustment of sound localization accuracy after inserting and removing monaural plugs in three owls *a–c* are owls 1–3, respectively The localization error of each owl is plotted as a function of its age The azimuth (●) and elevation (○) components of the error, derived as shown in Fig 1, are plotted separately The bar at the bottom of each graph shows the auditory history of the owl The limits of what we considered to be normal accuracy are indicated by the broken lines The asterisks on day 146 for owl 1 and on days 184 and 187 for owl 2 represent sessions in which the owls were unable to localize the sound target

lines in Fig 2) An owl was considered to have reached normal accuracy when its error fell within these limits on two consecutive days (In presenting these data, R signifies a localization error to the right of the source, L to the left, + above and − below) Owl 1 (left plug) was the youngest bird to be trained and tested At 16 weeks old, having been plugged for 12 weeks, the median error (±s d) of this owl was R 2 0°±3.1° in azimuth and −1 3°±3 5° in elevation (Fig 2*a*) Apparently, owl 1 had learned to localize with normal accuracy despite the severe monaural impairment caused by the plug At 113 days old the plug was removed, thereby restoring a strong (normal) binaural signal We tested owl 1 immediately and found its localization error had altered dramatically to L 6 7°±4 4° and down to −18 4°±4 1° The error not only remained large for the next 4 days, but increased slightly on the third day to L 7 8°±1 7° and −19 7°±4 7° On the fifth day, azimuth and elevation errors began to decrease sharply The azimuth and elevation errors returned to normal after 15 and 28 days, respectively

The pattern of auditory adjustments exhibited by owl 1 was mirrored by owl 2, in which the right ear was plugged (Fig 2*b*) By the first week of testing, at 21 weeks old, owl 2 had adjusted to the monaural occlusion its error was R 1 1°±4 0° and −1 0°±4 0° Just after removing the plug on day 146, its error changed to R 12 4°±4 6°, and +7 6°±4 5°, again, the largest localization errors occurred 2–4 days after the plug had been removed Azimuth errors declined rapidly after the second day and fell to within normal limits by day 11 Elevation errors peaked on the fourth day and returned to normal after 17 days

The performance patterns of owl 3 were different from those of the first two birds (Fig 2*c*) Owl 3 was 27 5 weeks old and had fully adjusted to the monaural impairment when its right plug was removed its localization error was L 1 9°±2 5° and −0 8°±4 1° After removing the plug its error changed to R 6 9°±3 3° and +6 2°±6 1° However, in this case adjustment to the unplugged condition was exceptionally slow the azimuth error took 25 days to correct and elevation error was still +3 7° after 70 days of normal experience The difference between owl 3 and the first two birds was the age at plug removal whereas owl 3 was 27 5 weeks old, owls 2 and 1 were 21 and 16 weeks old, respectively The data suggest that in the older bird the localization mechanism had become resistant to modification by experience before complete readjustment could occur

The implication that the localization mechanism becomes less plastic with age is supported by the results from owl 4 The right ear of owl 4 was occluded at 27 weeks of age (188 days) and kept occluded for the next 23 weeks, with no sign of adjustment Before the plug was removed the owl's error was still L 7 6°±2 1° and −12 4°±4 1°, and on the day after plug removal its localization accuracy was normal (R 0 7°±2 1° and 0 0°±1 8°) Thus, whereas the owls occluded at 4 weeks of age adjusted completely to the monaural impairment after only 12 weeks, owl 4 did not seem to adjust at all after 23 weeks

A second set of plugging experiments performed on owls 1 and 2 at 21 and 26 weeks of age, respectively, corroborate the results from owl 4 (Fig 2) We plugged the right ear of both owls, that is, the opposite ear for owl 1 and the same ear for owl 2 as were plugged the first time. Neither owl corrected for the induced localization error. Initially the data from owl 1 suggested some adjustment (Fig. 2*a*), but when the plug was removed after 33 days, the owl immediately localized with normal accuracy (0.0°±2.7° and +1.7°±2.5°). Similarly, owl 2, whose ear plug was still in place after 77 days, showed no sign of adjusting its error, which remained at L 10.8°±2.5° and −9.3°±3.7°. The lack of adjustment by owl 2 is particularly revealing because the induced hearing impairment was the same in the first and second experiments (right plug). The owl corrected its error the first time, but not the second. Hence the processes responsible for the adjustment in the first plugging experiment were inoperative in the second, again suggesting that plasticity in the localization mechanism disappears or decreases significantly with age.

During normal growth and development, this capacity for adjustment enables the owl to fine-tune its localization mechanism during the period in life when binaural cues are changing rapidly. After the owl reaches adult size and these cues stabilize, the calibration of the localization mechanism begins to crystallize and finally becomes resistant, if not immune, to further modification by experience.

Defective T-cell response in beige mutant mice

Rajiv K. Saxena, Queen B. Saxena & William H. Adler

Immunology Section, National Institute on Aging, National Institutes of Health, 4940 Eastern Avenue, Baltimore, Maryland 21224, USA

A role for T cells in immune surveillance has long been suggested[1], but the lack of high tumour incidence in T cell-deficient nude mice represented a challenge to this hypothesis. The discovery of natural killer (NK) cells, which can lyse tumour cells without any previous sensitization, and high NK levels in nude mice, suggested that these cells may constitute a first line of defence against spontaneously arising tumours *in vivo*[2]. Reports[3–5] of a selective NK deficiency and normal T-cell function in C57BL/6 mice carrying the beige mutation (*bg/bg*) suggested that these mice might be useful for assessing the relative importance of T-cell and NK-cell systems in immune surveillance. However we report here that the deficiency of beige mice is not restricted to NK cells. The generation of cytotoxic T lymphocytes (CTLs) in response to alloimmune challenge *in vivo* or *in vitro* was markedly impaired in beige mutants. Thus our results do not support the suggestion[3,5] that beige mice might be useful as a model of a selective NK deficiency.

To examine the generation of alloimmune CTLs in beige mice, 50 mutant (*bg/bg*) and heterozygous control (*bg/+*) mice (H-2^b) were immunized with a single intraperitoneal (i.p.) injection of P815 (H-2^d) tumour cells. Five mice from each group were killed at different time intervals after immunization and the anti-P815 cytotoxic activities of individual spleen cell preparations were determined at various effector/target ratios in a 4-h ^{51}Cr release assay[6]. Lytic units (LU) of alloimmune CTL activity were determined from the dose–response curves[7]. The P815 subline used in these experiments was not significantly susceptible to lysis by mouse NK cells, target lysis being 0.8–2.8% (effector/target = 100:1) by normal spleen cells from unimmunized mice and 2.5–5.4% by interferon-activated mouse spleen cells[7]. Results (see Fig. 1) indicate that the CTL activity in *bg/+* mice increased rapidly from day 5 and reached a peak value of 33 LU per 10^6 spleen cells on day 11. CTL response was specific to P815 target cells and was not observed against syngeneic EL-4 cells (results not shown). By day 17, the activity had declined considerably but a secondary challenge *in vivo* with 2.5×10^6 P815 cells increased the level of CTLs in *bg/+* mice observed 1 week after the second challenge. At all time points, anti-P815 CTL reactivity was markedly lower in *bg/bg* mice; the peak level of CTLs on day 11 was 11 LU per 10^6 spleen cells. Moreover, a secondary immunization did not increase CTL activity in *bg/bg* spleens. Lytic units in individual spleen cell suspensions indicated considerable variation between animals (Table 1). However, analysis of variance showed that the difference in generation of CTL activity

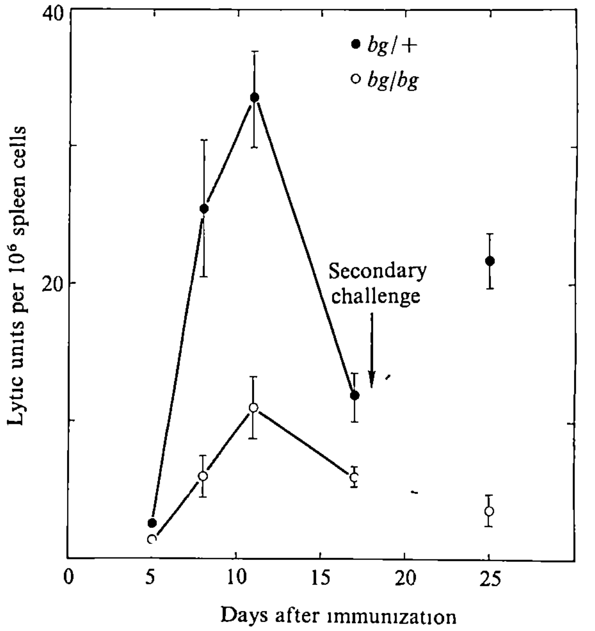

Fig. 1 On day 0, 6-week-old female *bg/bg* or *bg/+* mice were immunized by i.p. injection of 0.2 ml of a P815 tumour cell suspension containing 1×10^7 cells. Tissue-cultured P815 cells used for immunization were washed five times with normal saline before use. On days 5, 8, 11 and 17, five mice each from *bg/bg* and *bg/+* groups were killed and the anti-P815 immune T-cell reactivities of individual spleen cell preparations tested in a 4-h ^{51}Cr release assay at effector/target ratios of 100:1, 50:1, 25:1, 12:1, 12:1 and 6:1 as described previously[6]. Lytic units were calculated from the linear portion of semilog dose–response curves[7]. Each lytic unit represents a target cell lysis of 10% in the test system. Each point in the curve represents the mean ± s.e.m. of lytic units obtained from five spleen cell preparations. On day 18 mice were reinjected with another i.p. dose of P815 tumour cells (2.5×10^6 cells in 0.1 ml saline) and spleen T-cell cytotoxicity was examined on day 25. Spleen cells from unimmunized control mice had no detectable anti-P815 cytotoxic activity.

Error (includes animal-to-animal variation)	44	1,911 3	43 4	
Total	49	6,653 3		

* Each lytic unit represents 10% target lysis in the assay system and was computed from the linear parts of individual dose–response curves as described elsewhere[7]

between *bg*/*bg* and control mice was highly significant ($P<$ 0 001, Table 1)

Administration of tumour cells may induce two types of lymphocyte-mediated cytotoxic activity in mice An early augmentation of spleen NK activity peaks on the third day after tumour administration and falls rapidly thereafter to baseline levels by day 6 or 7 (ref 8) A second peak of specific alloimmune CTL activity occurs later, between days 10 and 11 after immunization[9] In our experiments, anti-P815 cytotoxic activity of spleen cells was first determined 5 days after immunization and the peak of cytotoxic activity occurred on day 11—a typical CTL response Treatment of spleen cells with monoclonal anti-Thy-1 antibodies and complement completely abolished their cytotoxicity for P815 target cells, confirming the T-cell nature of the effector cells (results not shown) The monoclonal anti-Thy-1 antibody used has previously been shown to abrogate completely immune T-cell reactivity with no significant effect on the levels of anti-YAC NK activity in spleen cells[10]

Table 2 Generation of cytotoxic T cells in a mixed lymphocyte reaction by *bg*/*bg* or +/+ mouse spleen responder cells

Source of spleen cells	Anti-P815 cytotoxicity generated in mixed lymphocyte culture (I U per 10^6 spleen cells)
+/+	132 4±13 7
bg/*bg*	39 2±5 4 ($P<0$ 001)

Responder spleen cells were derived from 11-week-old female *bg*/*bg* or +/+ mice (C57BL/6) In each experiment, 50×10^6 responder cells were incubated with 10×10^6 X-ray irradiated (1,000 rad) DBA/2 (12-week-old, female) spleen cells for 5 days in conditions described elsewhere[5] At the end of incubation, cells were washed and tested for cytotoxicity against ^{51}Cr-labelled P815 cells in a 3-h ^{51}Cr release assay at effector/target ratios of 100 1, 50 1, 25 1, 12 1, 6 1 and 3 1 Lytic units were calculated from the linear portion of the dose–response curve as described elsewhere[7] No significant cytotoxicity was detected in cultures without DBA/2 stimulator cells Each value is the mean± s e m of four experiments

Generation of alloimmune CTLs was also studied in a mixed lymphocyte culture system using a method described elsewhere[5], except that, instead of mitomycin treatment, the DBA/2 stimulator spleen cells were X-ray irradiated (1,000 rad) Results of four experiments (summarized in Table 2) indicate that the levels of cytotoxicity generated by *bg*/*bg* spleen cells in 5-day MLC were only 30% of control levels Cytotoxic activity generated in MLC experiments could also be totally abrogated by treatment with anti-Thy-1+complement (results not shown)

Thus, we could not confirm the presence of a normal T-cell function in *bg*/*bg* mice, the reason for the discrepancy between our data and those of Roder[3–5] is unclear The source of *bg*/*bg* and control mice (Jackson Laboratories) was the same for both studies A possible explanation is the considerable variation between animals in levels of alloimmune T cells generated in some beige mice, which can approach the lower limits of a normal response (Table 1) This variation was not reported in the previous study[3–5] and could have contributed to the apparent normality of T-cell function observed in *bg*/*bg* mice, in addition, cells from different mice were pooled and the immune T-cell activity of the pooled spleen cells determined In certain cases the results of assays using pooled spleen cells may not represent the mean of activities of individual spleen cell preparations[11] Finally, the data presented by Roder *et al* [3–5] did indicate a lower than normal level of concanavalin A-induced T cell-dependent cytotoxicity in *bg*/*bg* spleen cells (Figs 6, 8 of ref 5)

To compare the magnitude of the CTL induction defect in *bg*/*bg* mice with the NK cell defect, we attempted to quantify the NK activity in spleen cell preparations derived from *bg*/*bg* and *bg*/+ mice Anti-YAK NK lytic units per 10^6 spleen cells in *bg*/+ spleen cell preparations were 6 26±1 0 (mean ±s e m of eight mice) compared with <0 5 LU in *bg*/*bg* mouse spleen cells These results confirmed the previously reported NK defect in *bg*/*bg* mice[3–5]

Thus we have demonstrated a marked defect in beige mice in the generation of alloimmune T cells both *in vivo* and *in vitro* Whether the defect in T-cell response in *bg*/*bg* mice is generalized is unknown Significantly lower than normal CTL response to lymphocytic choriomeningitis virus infection has been demonstrated in *bg*/*bg* mice[12], whereas the response to vesicular stomatitis virus was approximately normal[13] It is therefore possible that a normal or a subnormal CTL response in *bg*/*bg* mice may depend on the antigen used Our preliminary findings stress the need for caution when using *bg*/*bg* mice as a model for a selective NK deficiency with normal T-cell function Small but significant differences in resistance to certain leukaemias between *bg*/*bg* and *bg*/+ mice[14] could result from a NK-cell defect or T-cell defect or both

We thank Ms Eleanor Wielechowski for secretarial help and Ms Charlotte Adler for preparing the figure

Further studies on supposed lamarckian inheritance of immunological tolerance

We have previously reported[1] an unsuccessful attempt to confirm the claim of Gorczynski and Steele[2,3] that tolerance to alloantigens, induced by the inoculation of F_1 hybrid spleen and bone marrow cells in newborn mice, can be transmitted by males to their offspring. Our study had been designed to reproduce the *in vitro* data of Gorczynski and Steele and to extend them by the transplantation of F_1 hybrid skin allografts. It followed that of Gorczynski and Steele[2] very closely but differed from it in two respects: the number of semi-allogeneic lymphoid cells in the inoculum used to establish tolerance in the fathers was 5×10^7 instead of 10^8 and the ratio of spleen cells to bone marrow cells was 9:1 rather than 1:1. Although we argued[1] that it is improbable that these differences of execution could have significantly affected the outcome of the experiments, our departure from the original protocol was nevertheless open to criticism[4] and the purpose of the present further study was to repeat the experiments by following Gorczynski and Steele[2] in every respect. We also report an attempt to confirm the work of Guttman's group[5,6], who claimed that a single CBA male made tolerant to A/J histocompatibility antigens, and mated with normal (CBA × A)F_1 females, produced offspring with a higher incidence of hypo- or unresponsiveness to A/J skin or tumour allografts than the offspring derived from normal males. We have again failed to confirm the work of Gorczynski and Steele and, like Steinmuller[7], we have been equally unsuccessful in confirming the observations of Guttman *et al.*

Five newborn CBA/Ca ($H\text{-}2^k$) males from two litters were made tolerant to A/J ($H\text{-}2^a$) histocompatibility antigens by the intraperitoneal (i.p.) inoculation of 10^8 adult male (CBA × A)F_1 hybrid spleen and bone marrow cells, mixed at a ratio of 1:1. These mice received 5×10^7 cells of the same cell mixture i.p. every 2 weeks throughout the breeding programme. Strain A tail skin allografts were transplanted to them soon after completion of breeding and 4 weeks after their splenic cells (obtained by partial splenectomy) had been tested in the cell-mediated lympholysis assay (CML). The mice were then ~4 months old, all accepted their grafts and were clearly fully tolerant whereas the six normal age-matched control fathers rejected their grafts in the expected manner at ~11 days.

Both tolerant and normal males were mated with groups of three normal CBA females of the same age and, when these had become pregnant, with a further group. Of the five tolerant males, one was sterile, as was one of the six controls. A total of 87 offspring from tolerant fathers ('experimental progeny') and 94 from normal fathers ('control progeny') were raised. Splenic CML data were obtained for 81 (93%) experimental and 79 (84%) control mice and all, with the exception of 4 experimental and 3 control mice that died as a result of partial splenectomy or after skin transplantation, were assessed for reactivity to (CBA × A)F_1 hybrid skin allografts. Skin grafting and assessment of graft survival, splenectomy, the splenic CML technique and the statistical analysis were exactly as described previously[1].

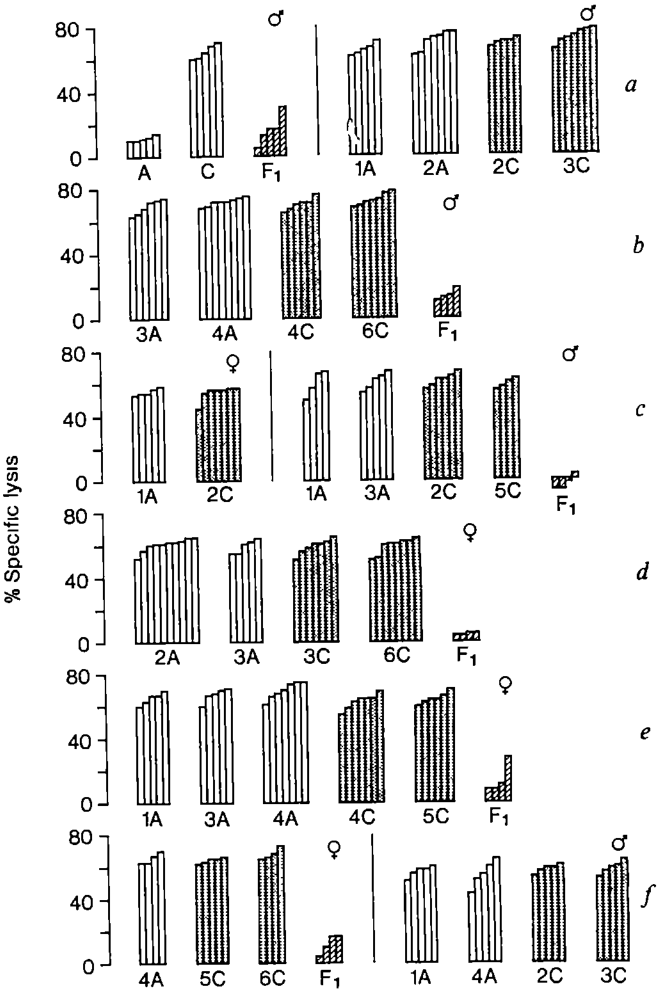

Fig. 1 Anti-A cytotoxic responses of spleen cells from tolerant fathers (A), normal control fathers (C), (CBA × A)F_1 hybrid mice (F_1) and progeny which are identified by the number of the father followed by A or C. Each panel represents the data from a separate experiment, the sex of the responders is indicated. The height of the bars, which represent responses of individual animals, is the % specific lysis at a killer/target ratio (K/T) of 5:1 derived from a 12-point log regression analysis. Groups 1A and 2C included in *a* were retested as shown in *f* (see text). Conditions of culture[1]: 4-ml Linbro wells were set up with 10^7 responder spleen cells and 10^7 irradiated (2,000 rad) strain A stimulator spleen cells per well in bicarbonate-buffered RPMI with 5% fetal calf serum, 5×10^{-5} M 2-mercaptoethanol, penicillin and streptomycin, glutamine and 10 mM HEPES. The assay was carried out on day 5 of culture. Cells were collected from wells, counted and serially diluted (two-fold) in round-bottomed 0.2-ml microtitre wells to which were added a constant number of ^{51}Cr-labelled target cells (24-h concanavalin A blast cells) to give K/T ratios starting at ~10:1. Supernatants were collected after 3 h incubation. Per cent specific lysis was taken as $(E-C)/(M-C)\times100$, where E was the c.p.m. for the experimental supernatant, C the c.p.m. for the medium control supernatant and M the c.p.m. of target cells lysed with 5% Triton.

All spleen suspensions were tested for their ability to respond following mixed lymphocyte culture not only against A antigens but also against 'third-party' C57Bl/10 antigens. The latter acted as a positive control to safeguard against technical failure and in all cases a good response was obtained, they are therefore not included in Fig. 1, which illustrates CML reactivity against the specific A antigens only. This time we confined ourselves entirely to the use of spleen cells for *in vitro* testing, as Gorczynski and Steele[2] had done in their original study, instead of using peripheral blood lymphocytes as well as spleen cells. Two changes were made to our previous protocol: first, the fathers were tested for CML reactivity at 4 months instead of 10 months and, second, (CBA × A)F_1 hybrid control mice were included in each of the major experiments to provide a baseline

Table 1 Survival of (CBA×A)F_1 hybrid skin allografts transplanted to the progeny of tolerant or control CBA males mated with normal CBA females

The sex of the graft donors and recipients was the same NA, not applicable

for the CML data Both changes must be regarded as improvements

Figure 1*a* shows that the experimental fathers (A) were indeed fully tolerant, thus confirming the skin graft data Not only do their responses show a highly significant difference when compared with the controls (C), but it is clear that they did not exceed the baseline provided by the F_1 controls The experimental males were, therefore, as tolerant as the F_1 controls The low level of cytoxicity in the F_1 mice is in agreement with the F_1 anti-parental cytotoxic responses described for other strain combinations[8] Because the tolerant fathers would be expected to be chimaeric for F_1 hybrid lymphoid cells it is possible that the presence of F_1 cells contributed to the low level of responsiveness shown by the tolerant fathers

As for the progeny, Fig 1*a–f* indicates that there were no differences of any interest between experimental and control progeny The differences between the control progeny and the F_1 mice were always highly significant ($P = 0$ 007–0 003) Only two experimental groups deserve special mention First, group 1A (Fig 1*a*) showed a borderline hyporesponsiveness compared with the male controls ($P = 0$ 04), but a repeat experiment some weeks later did not confirm this (included in Fig 1*f*) Second, group 4A (Fig 1*e*) was marginally hyper-responsive compared with all controls ($P = 0$ 01) and there was a slight hyper-responsiveness when all experimental and control mice of panel *e* were compared ($P = 0$ 02) No importance whatever is attached to this, especially as the anti-C57Bl/10 response by this group was also slightly greater than that of the controls ($P = 0$ 01) The conclusion is inescapable that the experimental progeny did not display the hypo- or non-responsiveness described by Gorczynski and Steele

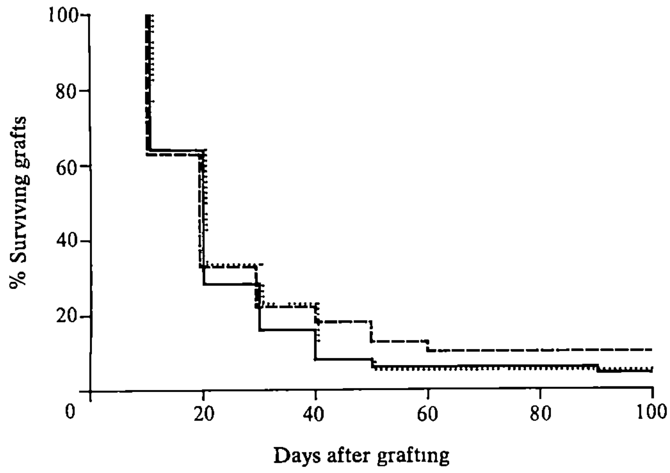

Fig. 2 Survival of female (CBA×A)F_1 tail skin grafts transplanted to the female progeny of tolerant and normal control CBA males mated with normal (CBA×A)F_1 females —— Tolerant, fathers received F_1 lymphoid cells at birth and every 2 weeks thereafter (79 mice), tolerant, fathers received F_1 cells at birth only (39 mice), --- normal fathers (40 mice)

The skin graft data again fully support this Table 1 lists the survival times of individual (CBA×A)F_1 hybrid grafts in experimental and control offspring It will be seen that they do not differ, and this is borne out by statistical analysis (males, $P > 0$ 3, females, $P > 0$ 2) Because F_1 grafts were used, a few were rejected a little more slowly than the majority, especially by male recipients, but this applied equally to the experimental and control progeny

We have therefore confirmed our previous study and failed to substantiate the claim that acquired immunological tolerance can be transmitted to offspring by tolerant male mice Other workers have experienced similar difficulties in a variety of models involving immunological tolerance, from neonatally induced tolerance[9–11], the tolerance of tetraparental[12 13] or adult parabiont[13] mice, to the natural tolerance that characterizes F_1 hybrids[14]

We are again unable to explain the discrepancy between our latest negative results and the original findings of Gorczynski and Steele Our study was, as before, conducted 'double-blind' in that those of us performing the *in vitro* test were presented with the splenic biopsies in coded form and the code was not broken until the data had been fully computed Care was taken to ensure that both skin grafting and graft assessment was carried out without bias We feel we have gone as far as is possible to repeat the precise conditions of the original study as reported by Gorczynski and Steele[2] and we must conclude that the phenomenon described by them was due to some special conditions prevailing in their laboratory Although that might still be of some interest it is unlikely that the lamarckian inheritance they postulate is of any importance in the evolutionary process, if indeed it exists

We have also failed in our attempt to confirm the observation by Guttman's group[5 6] that the offspring produced from a mating between a C3H male, made tolerant at birth by the inoculation of strain A spleen cells, and normal (C3H×A)F_1 hybrid females, accepted A strain skin allografts more readily than controls Two kinds of functionally tolerant males were used in our

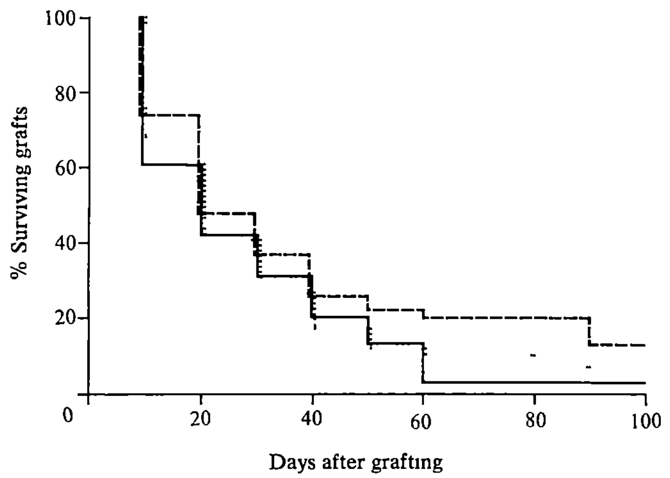

Fig. 3 Survival of male $(CBA\times A)F_1$ tail skin grafts transplanted to the male progeny of tolerant and normal control CBA males mated with normal $(CBA\times A)F_1$ females —— Tolerant, fathers received F_1 lymphoid cells at birth and every 2 weeks thereafter (64 mice), tolerant, fathers received F_1 cells at birth only (41 mice), - - - normal fathers (46 mice)

investigation 10 that had received 5×10^7 spleen and bone marrow cells at birth (in a ratio of 9:1) and the same number every 2 weeks until completion of the breeding programme (designated A), and 4 that had been injected at birth only (designated B). Controls (designated C) were provided by normal age-matched males. All offspring were grafted with $(CBA\times A)F_1$ skin 2–3 months after birth. The only ways in which our protocol differed (because it was carried out during another study[1]) were in the use of CBA mice in place of C3H, although these are compatible for H-2 antigens and similar to C3H mice, and in the use of a mixture of spleen and bone marrow cells. The mice were grafted in five batches over several months, with all groups represented in most batches, and it was sometimes difficult to assess with complete accuracy the end point of survival for grafts that had undergone a slow, insidious form of rejection.

Figures 2 and 3 show that there was no substantial difference between the progeny of groups A, B and C when comparing males with males and females with females. There is no statistically significant difference in the numbers surviving beyond 100 days between any of the groups. If the evaluation is made at 50 days, only the comparison between the male progeny of groups B and C shows a marginal but not significant difference, though in an unexpected direction in that the number of experimental B progeny with surviving grafts is lower than in the control group, using a one-tailed test (χ^2 2×2 test with Yates' correction for continuity, $P<0.05$). Like Steinmuller[7] we are therefore unable to confirm the claim by Guttman and his colleagues in the strain combination used by us.

All advocates of Lamarckism have insisted that the only valid test of whether or not it occurs is that based on the inheritance of specific adaptive changes acquired during an organism's lifetime. The immune response and its specific diminishment (tolerance) are admirably well suited to make the basis of a test for Lamarckism. In their original paper on tolerance, Billingham *et al*[15] (see also ref 9) found that the progeny of CBA parents both tolerant to A strain grafts reacted normally to such grafts, but they might have been mistaken because it was not at that time possible to measure alloimmunity as precisely as may be done today. The results reported here indicate that they were probably right and that in this experimental system acquired tolerance is not inherited.

All examples of supposedly lamarckian inheritance proposed so far[16] have been mistaken or open to more plausible explanations, especially in terms of selection. On the basis of our new evidence we can say with confidence that in respect of the systems we have been investigating, lamarckian inheritance does not obtain.

We thank Miss M Gaffiero and Mr D Conway for their technical assistance and the MRC and Joint Standing Research Committee of St Mary's Hospital for their support.

Adult haematopoietic cells transplanted to sheep fetuses continue to produce adult globins

In man, several primates, sheep and goats, fetal haemoglobin (Hb F: $\alpha_2\gamma_2$) is synthesized during the intra-uterine life, with a switch to adult haemoglobin (Hb A: $\alpha_2\beta_2$) production around birth. The mechanisms underlying the switches in globin gene expression are unknown. Studies of erythroid cell cultures suggest that haemoglobin switching is controlled at the level of haematopoietic progenitor cells[1,2]. To test whether interactions between the haematopoietic environment and the haematopoietic progenitor cells have a role in the haemoglobin switch, we transplanted adult cells into unrelated sheep fetuses at a time of gestation when only fetal haemoglobin was being produced in the recipient cells. We report here that there was engraftment of the donor cells and bone marrow chimaeras were formed. The donor cells, proliferating and differentiating in the fetal environment, continued to produce adult haemoglobin. These results suggest that the fetal environment does not contain elements capable of switching the adult haematopoietic cells to a fetal programme of haemoglobin synthesis.

In the sheep, gestation lasts ~145 days and the switch from fetal to adult globin formation usually starts at ~120–130 days and is completed shortly afterwards[3]. Fetuses younger than 110 gestational days typically have 100% fetal haemoglobin in their red cells (by chemical analysis). In the adult sheep there is a genetic polymorphism at the β locus of the adult haemoglobin[4] with two alleles β^B, providing chains for Hb B ($\alpha_2\beta_2^B$), and β^A, directing the synthesis of Hb A($\alpha_2\beta_2^A$). The existence of this genetic polymorphism allowed us to use haematopoietic cell transplantations to determine the regulation *in vivo* of haemoglobin switching[5] as follows. Bone marrow cells of an adult,

0028-0836/82/030244—03$01 00

homozygous Hb B donor were transplanted to fetuses produced by AA × AA crosses (and hence genetically homozygous for Hb A) that were at a gestational age when they produced only fetal haemoglobin We tested the red cells of the recipient for the presence of Hb B, to obtain information about (1) the fate of the transplanted cells, that is, whether or not, there was engraftment and (2) the globin synthesized by the cells after transplantation to the fetal environment For example, if after transplantation, there was no production of donor Hb B in fetal red blood cells but a chimaeric A/B sheep was born we could deduce that the donor cells were engrafted but had switched during fetal life to fetal globin formation Synthesis of Hb B during gestation and the birth of a chimaeric A/B animal would be evidence that the donor cells were engrafted but did not switch to fetal haemoglobin formation

We used pregnant ewes having confirmed dates of gestation Two heparin-filled polyvinyl catheters (0-9 mm o d) were inserted into the femoral artery and vein of the fetus Direct access to the fetal circulation was gained through a single midline incision of maternal skin and body wall, incision of the uterus, delivery of the fetal hind leg and placement of one catheter each into the fetal femoral artery and vein All incisions were then closed around the catheters, which were secured to the maternal skin, 48 h after surgery, each fetus received the donor bone marrow cells (4×10^8 nucleated cells per estimated kg fetal body weight), via the venous catheter, which was removed immediately after the bone marrow infusion Fetal blood samples were obtained via the arterial catheter for haemoglobin analysis before and at various intervals after infusion To minimize the risk of infection, the catheter was removed 3 weeks after the transplantation and the pregnancy allowed to go to term Blood sampling was resumed in the newborn in the case of successful deliveries

All the fetuses were at day 85–105 of gestation As the donors and recipients were unrelated, in the initial studies we attempted to suppress the haematopoiesis of the recipient fetus before transplantation The fetuses were irradiated or immunosuppressed but all the recipients died within 1–6 days after these manipulations Subsequently, we simply transfused the adult bone marrow cells into untreated fetuses Eleven AA fetuses were given bone marrow cells from the same unrelated female BB donor Six of these were aborted after this treatment, as autopsies were not done, the reason for these losses is unknown The haemoglobins of the five surviving fetuses were analysed by globin chain isoelectric focusing No β^B (donor) or β^A (recipient) globin chains were detected in any of the fetuses on days 1 and 4 post-transplantation, indicating that the minor contamination of the donor's buffy coat cells by red cells did not influence the haemoglobin phenotype of the fetus Two fetuses which were given infusions, respectively, on days 92 and 105 of gestation, failed to exhibit β^B chains (donor) both throughout the 3 weeks of post-transplantation intra-uterine blood-sampling and during postnatal sampling (up to 41 and 53 days, respectively, after birth)

Three fetuses were chimaeric A/B at birth One was studied only at birth and postnatally, a problem with the catheters did not allow intra-uterine sampling in this case This animal remained healthy and was A/B chimaeric throughout the period of sampling Two of the chimaeric fetuses were sampled *in utero* for 21 days post-transplantation One of them died after birth, but the second developed into a healthy animal which remained chimaeric Figures 1 and 2 show the results of haemoglobin analyses The adult haemoglobin of the donor was clearly detectable by day 7 post-transplantation and comprised 41% of the fetal haemoglobin by day 21 post-transplantation

The two living chimaeric lambs (a male and a female) produced both Hb B and Hb A at a ratio of 40 60 As the bone marrow donor was female, chromosomal studies were made of cells from the sole male chimaeric survivor Both donor (XX) and recipient (XY) karyotypes were noted for 50 cells, 58% of the lymphocytes were of the donor (XX) karyotype

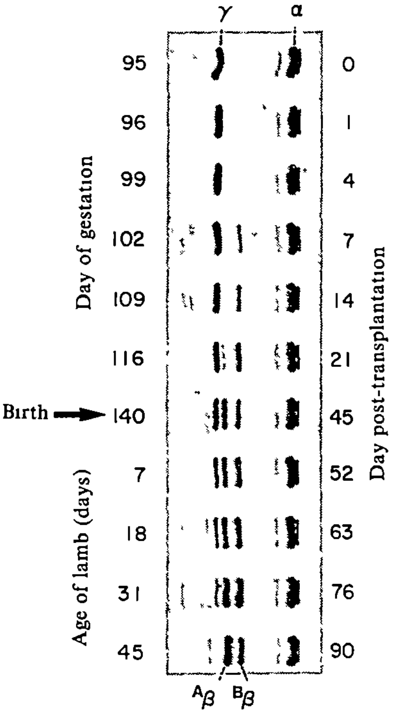

Fig 1 Globin-chain isoelectric focusing of lysates of blood samples obtained from a fetus pre- and post-transplantation Note the absence of detectable β-chains before transplantation and on days 1 and 4 post-transplantation The donor's β^B chains were detectable by day 7 and the intensity of the β^B zone increased thereafter Note also the appearance of significant amounts of β^A chains at birth and that the animal remained β^B/β^A chimaeric With the globin-chain isoelectric focusing method used[6], we achieved clear separation of the globin subunits Subunit β^C (from the inducible haemoglobin C $\alpha_2\beta^C_2$) migrates between subunits β^A and β^B We did not observe β^C-chain synthesis during the intra-uterine sampling of the animals with or without evidence of engraftment The AA fetuses were given cells from the same 2 4-yr old female donor (see text)

Donor bone marrow cells were obtained by multiple aspirations from different sites on the posterior iliac crest The heparinized bone marrow samples were filtered through a screen mesh to remove large particles, the filtrate was allowed to settle at room temperature for 15 min and the supernatant and buffy-coat layers were removed and passed through needles of progressively smaller pore sizes to achieve a single-cell suspension The cells were resuspended in Hanks' balanced salt solution containing the recipient's own plasma (5% v/v) at a concentration of 4–7×10^7 nucleated cells ml^{-1} In all cases the cells were infused into the fetus within 1–2 h of aspiration

These results raise questions for cell immunology and transplantation biology Successful grafts were observed in three of the five animals surviving to birth and all the donor–recipient pairs were unrelated The data suggest that in adult fetus transplantation, conditions may exist which both allow tolerance of the donor cells and diminish the possibility of severe graft-versus-host disease Confirmation of the findings of our experiments and similar studies in primates may have practical relevance If untreated primate fetuses are infused with bone marrow cells from unrelated donors a chimaeric primate may be formed Thus, intra-uterine transplantation of adult bone marrow cells could be considered as an alternative to abortion, when, on prenatal diagnosis, a human fetus is found to be homozygous for a β-chain haemoglobinopathy (such as β-thalassaemia or a Hb S syndrome)

The cellular mechanisms involved in the haemoglobin switch during ontogeny are unknown The question remains as to whether the switch from fetal to adult globin formation is intrinsic to the cell (that is, due to the operation of a developmental clock which informs the cells when or after how many divisions the switch will occur) or whether it is the result of haematopoietic cell–environment interactions If such interactions are involved, are there specific factors present during fetal life or produced during and after the switch-over period which influence the programme of the progenitor cells?

To test the possibility of environment–cell interactions we have previously transplanted haematopoietic cells from pre-switch sheep fetuses into lethally irradiated adult recipients We used the A and B polymorphism of the sheep and in one successful experiment, found that the fetal cells switched to adult globin expression when grafted in to the adult environment[5] There are two possible interpretations of these results (1) the adult environment influenced the programme of the transplanted haematopoietic cells and accelerated the switching process, (2) the transplanted cells were intrinsically programmed to switch and did so in their new environment In the

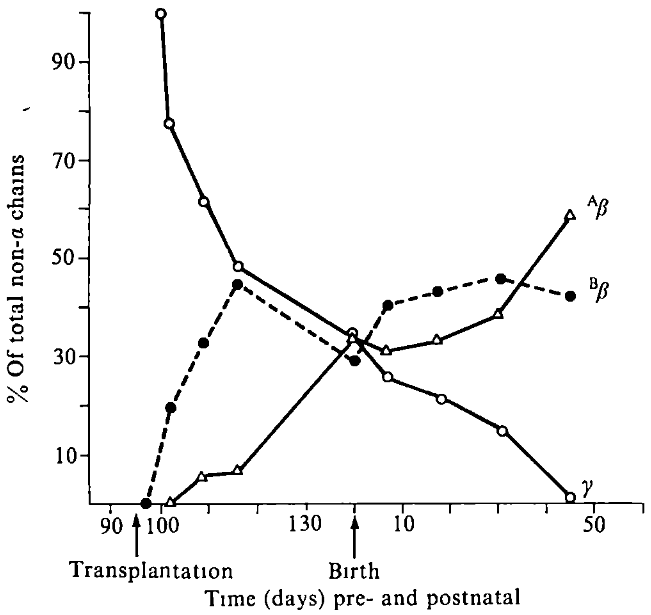

Fig. 2 Proportion of γ, β^A (recipient) and β^B (donor) chains in the haemolysates of blood samples periodically drawn from a fetus (gel shown in Fig 1) Note the striking prenatal increment in the donor's β^B chains, and the lower proportions of β^B chains at birth compared with the prenatal maximal value After the γ- → β-chain switch was complete, the level of β^A chains (derived from the recipient's cells) exceeded the level of β^B chains (originating from the donor cells) A remarkable aspect of these quantitative analyses is the pre- and post-natal proportion of the donor β^B chain The findings are compatible with two peaks of β^B synthesis, one ~20 days post-transplantation and the second 20–30 days after birth A plausible interpretation is as follows The first peak of β^B chain synthesis derives from red cells which have been formed by transplanted committed erythroid stem cells These progenitors have amplified, differentiated, been committed to erythroblastic maturation and have provided the fast rising level in donor haemoglobin after infusion of the donor bone marrow cells The postnatal peak, on the other hand, is derived from red cells produced by the engrafted pluripotent stem cells from the donor

adult → fetal transplantation experiments reported here, we found that the adult donor cells produced large amounts of adult haemoglobin at a time when the cells of the fetuses had not switched to adult haemoglobin synthesis, this suggests that the donor cells continued to follow their adult globin programme even under the influence of the fetal environment The adult → fetal transplantations results are consistent with the mechanisms suggested by the findings of the fetal → adult haematopoietic cell transplantations If the switch from Hb F to Hb A formation is intrinsically controlled, the adult cells did not switch to fetal globin expression because their programme of differentiation had already been intrinsically changed If environment–cell interactions control the switch, both the fetus → adult and adult → fetus transplantations point to the establishment of an 'adult' haematopoietic environment as an underlying cause of the changes in haematopoietic cells effecting haemoglobin switching

Although further experiments are required to assess individually the programmes of the various classes of donor progenitor cells that were transplanted to these fetuses, the data presented here provide evidence against the possibility that there existed at the developmental time of these transplantations, an environment able to switch adult cells to typical fetal haemoglobin synthesis

Thrombospondin is the endogenous lectin of human platelets

Eric A. Jaffe*, Lawrence L. K. Leung*, Ralph L. Nachman*, Richard I. Levin* & Deane F. Mosher†

* Department of Medicine, Cornell University Medical College, New York, New York 10021, USA

Platelets activated by α-thrombin change shape from disks to spheres and aggregate. During this sequence of activation, platelets develop a membrane-bound lectin activity[1,2] which is expressed after the secretion of intracellular granule contents[3]. This lectin activity seems to be important in mediating platelet aggregation by binding to a specific receptor on other platelets. Gartner *et al.*[4] have recently shown that fibrinogen is the receptor for the endogenous lectin secreted by activated platelets. Thrombospondin[5] (also called glycoprotein G[6] and thrombin-sensitive protein[7,8]) is an α-granule constituent which has a molecular weight (MW) of 450,000 and is a disulphide-linked trimer of 160,000 MW subunits[5,9,10]. Secreted thrombospondin[5–14] binds to platelet membranes in a calcium-dependent manner[12]. We show here that thrombospondin is the endogenous lectin of human platelets.

Thrombospondin and other proteins were tested for lectin activity using minor modifications of the haemagglutination system described by Gartner *et al* [1–4] If thrombospondin is the endogenous lectin of platelets, it may act directly as a haemagglutinin Because thrombin-treated but not native platelets have lectin activity[2 4], we used fixed (formaldehyde-treated) native platelets and fixed thrombin-treated platelets as controls in the haemagglutination assay As expected, fixed native platelets had no lectin activity (Table 1) whereas fixed thrombin-treated platelets had lectin activity and agglutinated fixed trypsin-treated sheep erythrocytes at a dilution of 1 16 (a titre of 16) This haemagglutination was blocked by α-D-mannosamine or α-D-glucosamine but not by *N*-acetylmannosamine or *N*-acetylglucosamine These same inhibitors have previously been shown to block both platelet plasma membrane lectin activity detected using bovine erythrocytes[1] and thrombin-induced platelet agglutination[4] When tested in the same system, thrombospondin purified from human platelets had strong lectin activity (haemagglutinin titre of 256, Table 1) This lectin activity was blocked by glucosamine and mannosamine but not by *N*-acetylglucosamine or *N*-acetylmannosamine In contrast, purified human serum albumin, fibronectin, factor VIII, fibrinogen and plasminogen tested as controls had no lectin activity

If thrombospondin is the endogenous platelet lectin, excess exogenous thrombospondin may also inhibit the haemagglutinating activity of thrombin-treated platelets by blocking thrombospondin receptors To test this hypothesis, proteins were serially diluted, sheep erythrocytes and fixed thrombin-treated platelets then added and haemagglutination was assessed A buffer control did not block haemagglutination (Table 2)

Table 1 Lectin activity of thrombospondin

Diluted material	Titre
Fixed native platelets	0
Fixed thrombin-treated platelets	16*
Thrombospondin	256*
Human serum albumin	0
Fibronectin	0
Factor VIII	0
Fibrinogen	0
Plasminogen	0

Haemagglutination of sheep erythrocytes was assayed in microtitre 'V' plates (Cooke Engineering Laboratory Products) as described by Gartner *et al.*[1–4] 25 μl of Tris-buffered saline containing calcium (TCS buffer: 10 mM Tris-HCl, 2 mM CaCl$_2$, 150 mM NaCl, *p*H 7.4) was added to each well, then 25 μl of the diluted material was added to the first well in a row of 12 wells and was serially diluted twice in duplicate series of 11 wells. The remaining well in each series contained no diluted material and served as control. Finally, 25 μl of a 2.5% suspension of trypsin-treated, formalinized sheep erythrocytes in TCS buffer prepared as described by Gartner *et al.*[1–4] was added to each well. The wells were agitated gently and evaluated for haemagglutination after standing overnight at room temperature. The titre of diluted material is defined as the reciprocal of the end point dilution (greatest dilution that gives agglutination). Fixed thrombin-treated platelets were prepared as follows. The platelets in 200 ml of fresh platelet-rich plasma were pelleted, washed once with 120 mM KCl, 75 mM Tris-HCl, 12 mM sodium citrate, *p*H 6.3, twice with 150 mM NaCl, 10 mM Tris HCl, 1 mM EDTA, *p*H 7.4 (ETS), and then resuspended in 5 ml ETS. The resuspended platelets were treated for 2 min at room temperature with human α-thrombin (3 units ml^{-1}, a gift of Dr John Fenton II) and washed once with ETS and once with 0.15 M NaCl, 10 mM Tris HCl, *p*H 7.4 (TS buffer). The resulting pellet was resuspended in 2% paraformaldehyde in phosphate-buffered saline and incubated overnight at 4 °C. The fixed platelets were washed four times with phosphate-buffered saline and resuspended in TS buffer at a concentration of 350,000 μl^{-1} and stored at 4 °C until use. Fixed native platelets were prepared by mixing fresh platelet-rich plasma with an equal volume of 4% paraformaldehyde in phosphate-buffered saline and incubating overnight at 4 °C. These platelets were washed as above, resuspended in TS at a concentration of 350,000 μl^{-1} and stored at 4 °C until used. Thrombospondin was prepared from 4 units of platelets by the method of Lawler[5]. The thrombospondin was >95% pure and contained no fibrinogen when analysed by SDS-polyacrylamide gel electrophoresis (SDS-PAGE). The human serum albumin was obtained from Behring. The purified peak I human fibrinogen was provided by Dr M. Mosesson[32] and was >96% clottable and homogeneous on SDS-PAGE. The human plasma factor VIII was prepared from plasma by methods previously described[33] and did not contain fibronectin or plasminogen when analysed for these proteins by enzyme-linked immunosorbent assay. The purified human plasminogen[34] and fibronectin[35] were gifts from Dr P. Harpel. The factor VIII, plasminogen and fibronectin were absorbed with insolubilized anti-human fibrinogen and were negative for fibrinogen by an enzyme-linked immunosorbent assay. All proteins were added to the first well as 25 μl of a solution of 0.2 mg ml^{-1}.

* This agglutination was inhibited by a 57 mM final concentration of either α-D-mannosamine or α-D-glucosamine but not by 57 mM *N*-acetylmannosamine or *N*-acetylglucosamine.

whereas thrombospondin blocked haemagglutination with an inhibitory titre of 8 (final concentration of thrombospondin in last inhibited well is 6.3 μg ml^{-1}). Human serum albumin and fibronectin inhibited haemagglutination only weakly. Fibrinogen also strongly inhibited haemagglutination with an inhibitory titre of 16 in the presence or absence of calcium. These latter results are at variance with those of Gartner *et al.*[4], who found that fibrinogen inhibited haemagglutination only in the absence of calcium. The discrepancy may be due to the fact that the platelets used in our studies were fixed in formaldehyde after thrombin treatment.

Table 2 Thrombospondin blocks haemagglutination by fixed, thrombin-treated platelets

Diluted material	Inhibitory titre
Buffer	0
Thrombospondin	8
Human serum albumin	2
Fibronectin	2
Fibrinogen	16

The materials listed were added as 25 μl of a solution of 0.2 mg ml^{-1} to 25 μl of TCS buffer and serially diluted as in Table 1. 5 μl of a 12.5% suspension of trypsin-treated, formalinized sheep erythrocytes and 25 μl of fixed thrombin-treated platelets diluted 1:4 with TSC buffer (haemagglutination titre of undiluted fixed thrombin-treated platelets was 16, see Table 1) were then added and the microtitre plates agitated, incubated overnight at room temperature, and read. The inhibitory titre of a diluted material is defined as the reciprocal of the greatest dilution which inhibited haemagglutination compared with a control without any diluted material. Other details are as in Table 1 legend.

Table 3 Thrombospondin blocks the agglutination of fixed, thrombin-treated platelets

Diluted material	Inhibitory titre
Buffer	0
Thrombospondin	16
Factor VIII	0
Human serum albumin	1
Fibonectin	2
Plasminogen	2
Fibrinogen	16

The materials listed were serially diluted as in Tables 1 and 2. 25 μl of fixed thrombin-treated platelets diluted 1:4 with TCS buffer were then added and the microtitre plates agitated, incubated overnight at room temperature and read. The inhibitory titre of a diluted material is defined as the reciprocal of the greatest dilution which inhibited agglutination compared with a control without any diluted material. Other details as in Table 1 legend.

Fixed thrombin-treated platelets also agglutinate when tested alone in a microtitre assay system (titre of 32). If thrombospondin is the endogenous lectin of platelets, excess exogenous thrombospondin may also inhibit the agglutination of fixed thrombin-treated platelets by blocking thrombospondin receptors. To test this possibility, proteins were serially diluted, fixed thrombin-treated platelets added and agglutination assessed (Table 3). Buffer did not inhibit agglutination whereas thrombospondin strongly inhibited agglutination. Factor VIII, human serum albumin, fibronectin and plasminogen inhibited agglutination only very slightly or not at all. Fibrinogen, however, strongly inhibited agglutination.

Of the proteins tested, only thrombospondin had lectin activity (Table 1), blocked haemagglutination by fixed thrombin-treated platelets (Table 2) and blocked the agglutination of fixed thrombin-treated platelets (Table 3). None of the other platelet granule proteins tested had lectin activity and only fibrinogen blocked haemagglutination or platelet agglutination. Studies of other α-granule proteins have shown that neither β-thromboglobulin nor platelet growth factor has lectin activity[15]. Further, although platelet factor 4 was shown to have agglutinating activity[15], it differed from the lectin activity of thrombin-stimulated platelets[2] or thrombospondin in that it was not blocked by mannosamine or glucosamine and was not trypsin sensitive[15]. These observations thus support our conclusion that thrombospondin is the platelet lectin.

The observations that thrombospondin has lectin activity, is a multimer and by itself causes haemagglutination (Table 1) suggest that thrombospondin is a multivalent molecule. The ability of thrombospondin to block haemagglutination and platelet agglutination at low concentrations (6.3 and 3.1 μg ml^{-1}, respectively) suggests that thrombospondin binds with high affinity to its receptor. The blocking effect of fibrinogen is compatible with the recent observation of Gartner *et al.*[4] that fibrinogen is the receptor for the endogenous lectin of platelets. If platelets interact with each other during aggregation via intercellular bridges of thrombospondin anchored to platelet-bound fibrinogen, excess free fibrinogen in an agglutination or haemagglutination assay would react with thrombospondin and block the reaction. The same reasoning applies to the blocking effect of thrombospondin. Our data are also compatible with the recent observation that the platelets from patients with the grey platelet syndrome (which lack α-granules and their constituents, including thrombospondin) are deficient in thrombin, ADP and collagen induced aggregation[16].

Other proteins in platelet granules—for example, factor VIII/von Willebrand factor[17–19], factor Va[20–22], fibrinogen[23–25] and fibronectin[26]—also have major roles in platelet function. Furthermore, it is interesting that endothelial cells, which synthesize von Willebrand factor[27,28] and fibronectin[29], also synthesize thrombospondin[30,31]. Although the level of thrombospondin in plasma as measured by radioimmunoassay is quite low (D.F.M. and E.A.J., unpublished results), endothelial cells in certain conditions may release thrombospondin in a local microenvironment and thus support platelet function

A microtubule-associated protein in the mitotic spindle and the interphase nucleus

Jonathan G. Izant*, James A. Weatherbee† & J. Richard McIntosh*

* Department of Molecular, Cellular and Developmental Biology, University of Colorado at Boulder, Boulder, Colorado 80309, USA
† Worcester Foundation for Experimental Biology, Shrewsbury, Massachusetts 01545, USA

Accurate chromosome segregation during mitosis is contingent on the controlled polymerization and function of spindle microtubules. Assembly-promoting polypeptides that co-sediment with microtubules during cycles of polymerization *in vitro* are attractive candidates for regulators of the formation and function of the mitotic apparatus *in vivo*. However, previous work has shown that the major species of microtubule-associated proteins (MAPs) from mammalian brain or tissue culture cells are either not associated with the mitotic spindle[1] or are associated with both mitotic and interphase cytoplasmic microtubules[2–4]. We have therefore sought a novel way to identify spindle regulatory factors. In the study reported here, monoclonal antibodies have been prepared against a MAP fraction from HeLa cells. One of the resulting hybridoma clones produces IgG that binds to a polypeptide of molecular weight ~200,000. During cell division this antigen is associated with fibres in the mitotic apparatus, but in interphase it is located primarily in the nucleus. Surprisingly, the antigen is also detectable on the plasma membrane of circulating human erythrocytes. This spindle component is distinct from previously characterized MAPs and may represent a regulatory factor in the assembly and function of the mitotic apparatus.

The molecular factors controlling the assembly and function of the mitotic spindle are largely unknown Interphase microtubules in lysed cell models display a calcium lability that is modulated by MAPs[5], suggesting that the polypeptides which co-purify with cytoplasmic microtubules may have important regulatory functions Other potential regulatory proteins, such as calmodulin[6] and cyclic nucleotide-dependent kinase[7], have been localized in the mitotic spindle, but although this suggests several models for spindle regulation, the actual functions of these enzymes during chromosome separation remain speculative

We have been studying MAPs from cultured cells using the lymphocyte hybridoma methodology to identify specific mitotic spindle components. Using a crude mixture of HeLa cell MAPs purified by cycles of co-assembly with HeLa tubulin and by ion-exchange chromotography[8] as initial innoculum, we have screened for spindle antigens by radioimmunoassay and immunofluorescence microscopy The antibody produced by hybridoma clone 0-2D5 3 1 binds a polypeptide from HeLa cells with an approximate molecular weight of 200,000 (Fig 1) The 0-2D5 antigen is sensitive to endogenous protease both in purified microtubule protein preparations and in whole-cell homogenates[9], as are the high-molecular weight MAPs from brain[10] The 0-2D5 antibody preparation produces a distinctive punctate nuclear immunofluorescent staining pattern in interphase human cells and stains mitotic spindle fibres intensely (Fig 2) The interphase microtubule array stains only faintly (Fig 2*a*, *b*) The fluorescent nuclear dots range in number from

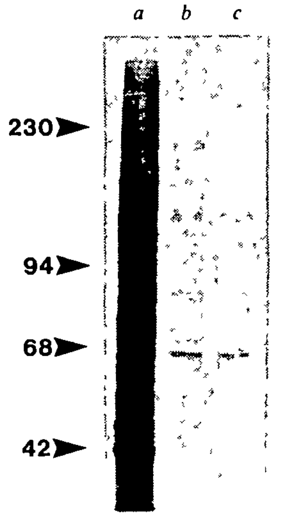

Fig. 1 Immunoprecipitation of HeLa cell MAP Autoradiograph of ^{35}S-methionine-labelled HeLa cell homogenate (*a*) and *Staphylococcus aureus* immunoprecipitates[-7] using 0-2D5 3 1 antibody (*b*) and a control monoclonal antibody (*c*) run on a 7 5% SDS-polyacrylamide gel[18] The 0-2D5 antibody specifically precipitates a protein of molecular weight ~200,000, while there are several additional polypeptides that bind nonspecifically to both immune complexes Molecular weight markers were fibronectin (230,000), phosphorylase *a* (94,000), bovine serum albumin (68,000) and ovalbumin (44,000) The MAP fraction used as antigen was prepared by ion-exchange chromatography of four times-cycled HeLa cell microtubule protein as described elsewhere[8] BALB/c mice were immunized intraperitoneally with 100 μg of SDS-denatured HeLa MAPs emulsified in an equal volume of Freund's complete adjuvant Twenty-one days later the mice were boosted intravenously with 50 μg of MAPs in saline After another 4 days splenic lymphocytes were collected and fused with SP2/0 myeloma cells as previously described[1] Hybridomas were screened by a solid-phase radioimmunoassay, and cells producing specific antibody were cloned twice in soft agar Immunoglobulin from 1 0 l suspension cultures was concentrated 100-fold by 40% ammonium sulphate fractionation and the IgG purified by chromatography on Affi-gel Blue CM (Biorad), followed by another ammonium sulphate precipitation

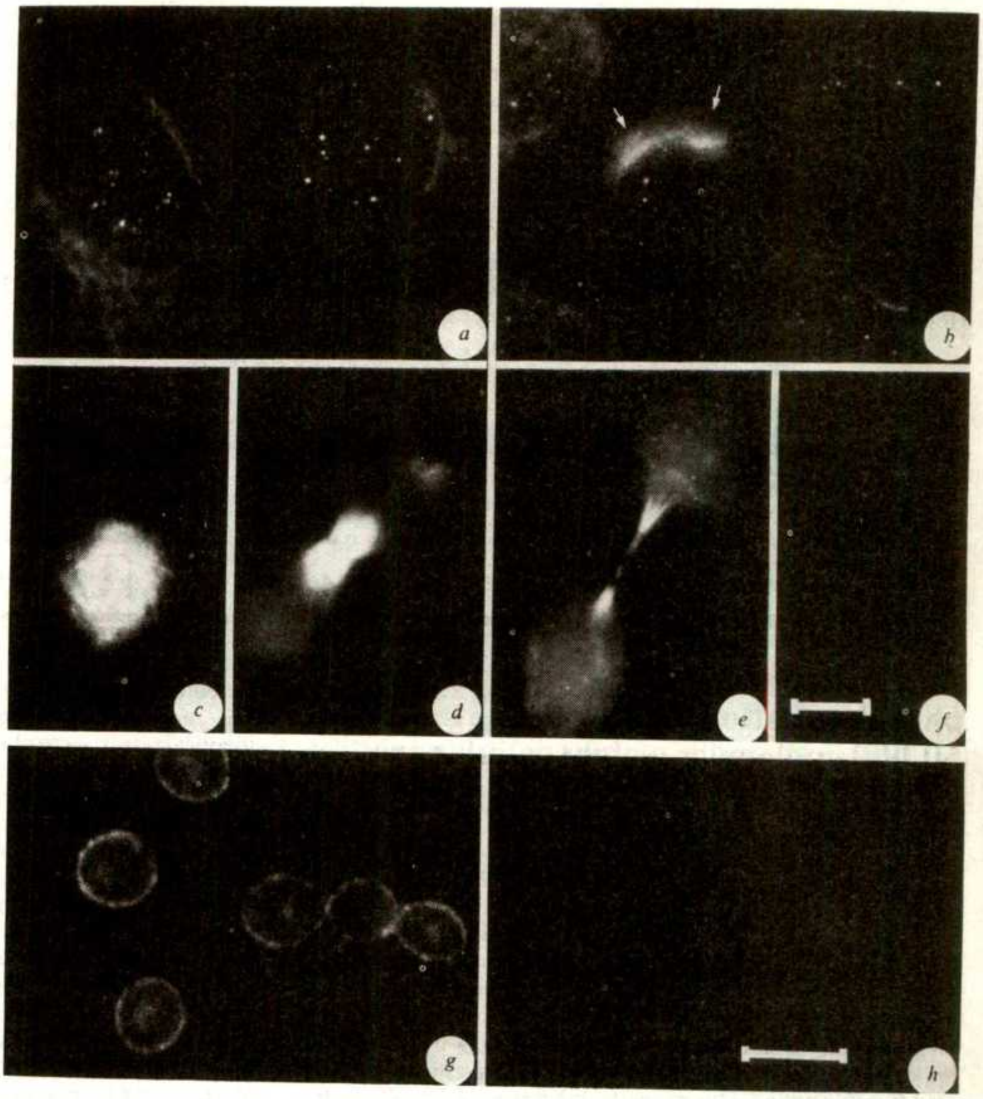

Fig. 2 Indirect immunofluorescent staining pattern of HeLa (*a*, *b*, *d–f*) and Va90 (*c*) cells and human erythrocytes (*g*, *h*). Cells were stained with anti-MAP antibody secreted by hybridoma 0-2D5.3.1 (*a–e*, *g*) or with a control mouse monoclonal preparation (*f*, *h*). The 0-2D5 antibody stained the interphase nucleus (*a*, *b*) and the enlarging prophase asters (*b*, arrows) in human cells. The mitotic spindle stained intensely (*c–e*) with the punctate pattern reappearing during telophase (*e*). The antibody also stained the plasma membrane of circulating erythrocytes (*g*). Tissue culture cells were grown on coverslips in minimal essential medium supplemented with 10% calf serum, rinsed in saline, fixed in 100% methanol at −20 °C for 4 min, postfixed in acetone at −20 °C for 1 min, rehydrated in saline and then processed for immunofluorescence microscopy as previously described[1]. Human erythrocytes were diluted in saline, settled on coverslips and fixed with 2% paraformaldehyde before being permeabilized and stained as above. The secondary antibody was tetramethylrhodamine-labelled goat anti-mouse immunoglobulin (USA Biochemicals) at a 1:50 dilution in 20% goat serum. Specimens were examined on a Zeiss photoscope III equipped with epifluorescence optics, and fluorescent images were recorded on Plus-X film. Scale bar, 5 μm.

14 to 43 and appear to be randomly intranuclear; they are not associated with the nuclear envelope as judged by through-focus examination at high magnification. The punctate pattern of antibody staining disappears during prophase and reappears in association with the decondensing chromatin during telophase (Fig. 2*b*, *d*). There is no evidence of fluorescent dots in metaphase or anaphase cells (Fig. 2*c*, *d*). The spindle fibre staining is apparent even during early prophase when the antibody stains the nascent asters (Fig. 2*b*). No concomitant increase in the staining of the residual interphase microtubule network is observed during this stage. Similarly, the 0-2D5 anti-MAP antibody stains the spindle remnant (midbody) during telophase (Fig. 2*e*), again without significant staining of the arrays of interphase microtubules assembling in the daughter cells. The 0-2D5 antibody does not cross-react with cultured cells of non-human primate, rodent, or marsupial origin, but it does stain the plasma membrane of human erythrocytes (Fig. 2*g*, *h*). No surface staining has been observed in any other cell type tested.

The origin, molecular weight and cellular distribution of the 0-2D5 MAP distinguish it from the major MAPs of brain microtubule protein. The differences between previously published micrographs[4] of anti-MAP staining and the punctate nuclear immunofluorescent images shown here suggest that the set of high-molecular weight HeLa MAPs contains structurally and functionally distinct protein species. The 0-2D5 antigen is also distinct from nuclear mitotic apparatus protein (NuMA), another high-molecular weight antigen found in the interphase nucleus and in association with the mitotic spindle of human cells[11]. The electrophoretic mobility of NuMA and the staining pattern of anti-NuMA monoclonal antibodies (S. E. Winston and D. E. Pettijohn, personal communication) clearly differ from those of 0-2D5 antigen. NuMA was originally isolated as a non-histone chromatin-associated protein and may be involved in the organization or expression of DNA. At present there is insufficient data to determine whether the foci stained by 0-2D5 have structural or enzymatic activity associated with chromatin or the nuclear matrix.

There are striking similarities between a spectrin-binding protein in human erythrocyte membranes called ankyrin or syndein and the 0-2D5 antigen. Both are easily proteolized proteins of molecular weight 200,000 which associate with structural polypeptide polymers (ref. 12; Fig. 1). Antiserum against ankyrin produces spotted nuclear immunofluorescent images and stains the mitotic apparatus in tissue culture cells (V. Bennett, personal communication). Nucleated erythrocytes from birds and amphibians have characteristic circumferential bands of microtubules which contain MAPs[13]; thus the similar distribution of ankyrin and the 0-2D5 MAP raises the intriguing possibility that these antigens have common antecedents as well as similar functional characteristics.

There is no indication, as yet, whether the 0-2D5 antigen, ankyrin or NuMA are necessary spindle components which are sequestered in the nucleus during interphase, or if the antigens function primarily in the interphase nucleus and bind to spindle fibres simply to assure partition into the daughter cells. The rather surprising similarity between an erythrocyte membrane component and a cultured cell MAP suggests that these proteins, or different oligomers of which they are a subunit, may have distinct functions depending on the cellular environment. They may be members of a family of multifunctional molecules like tubulin that are used in different ways according to the stage of the cell cycle or the programme of cellular differentiation.

The data presented here are consistent with the hypothesis that a subset of mitotic spindle components is sequestered in the nucleus during interphase and that nuclear envelope breakdown initiates or augments spindle assembly by releasing important factors into the cytoplasm[14,15]. Detergent-lysed cell models do show an increased ability to nucleate aster microtubules after the breakdown of the nuclear envelope[16]. Generalizing this theory is difficult in view of the variety of organisms that do not dissolve or fenestrate their nuclear envelopes during mitosis. However, the 0-2D5 antigen appears on early prophase asters, suggesting that additional mechanisms may be working to allow or promote the association of this antigen with a specific subset of cytoplasmic structures. The preferential association of the 0-2D5 MAP with mitotic apparatus microtubules supports its identification as a spindle MAP and strengthens its candidacy for a mitotic spindle regulatory factor. Microinjection studies are being done to elucidate the role of the 0-2D5 MAP during spindle formation and chromosome separation.

We thank Bill Wood for making available his epifluorescence microscope and Susan Strome for helpful criticism of the manuscript. This research was supported by grant CD-8D from the American Cancer Society and USPHS award CA-28078 from the NCI.

Rous sarcoma virus-induced phosphorylation of a 50,000-molecular weight cellular protein

Joan S. Brugge & Diane Darrow

Department of Microbiology, State University of New York at
Stony Brook, Stony Brook, New York 11794, USA

Transformation by Rous sarcoma virus (RSV) is mediated by a single virus-encoded polypeptide, pp60$^{\mathrm{src}}$ (refs 1–3), which has protein kinase activity specific for tyrosine residues[4–7]. The identification of the proteins phosphorylated by pp60$^{\mathrm{src}}$ is important in understanding the events involved in RSV-mediated transformation. One potential substrate is a 50,000-molecular weight (MW) phosphotyrosine-containing protein (pp50) which is associated in a complex with pp60$^{\mathrm{src}}$ and a cellular 90,000-MW protein (pp90; ref. 8) and thus is immunoprecipitated by antibody to pp60$^{\mathrm{src}}$ (refs 6, 9, 10). We have performed further studies to determine whether this 50,000-MW protein (pp50) is present in uninfected cells and whether its phosphorylation at tyrosine depends on RSV-induced transformation. Here we demonstrate that a phosphoserine-containing form of pp50 is present in uninfected chicken cells and that on transformation by RSV, a second form of pp50, detectable by two-dimensional analysis of ^{32}P-labelled proteins, contains phosphotyrosine as well as phosphoserine. This phosphorylation of pp50 at tyrosine is not temperature sensitive (ts) in cells infected with mutant viruses containing a ts defect in the *src* gene. Previous results[8] have suggested that the temperature stability of this phosphorylation might be a result of the strong interaction between the mutant pp60$^{\mathrm{src}}$ protein and pp50.

To identify pp50 on two-dimensional gels of ^{32}P-labelled chicken cell lysates, a mixing experiment was performed (Fig. 1). First, using serum from tumour-bearing rabbits (TBR), pp50 was immunoprecipitated from ^{32}P-labelled chicken cells transformed by the SR-A strain of RSV. Two-dimensional gel electrophoresis of this immunoprecipitate using ampholytes enriched in the *p*H 5–7 range resolved pp50 ($pI = 5.4$; Fig. 1*a*). Comparison of the two-dimensional gel patterns of uninfected cell phosphoproteins (Fig. 1*b*) with a mixture of the TBR immunoprecipitate and uninfected cell phosphoproteins (Fig. 1*c*) indicated that the pp50 which is bound to pp60$^{\mathrm{src}}$ and precipitated from RSV-transformed cells (pp50A) migrates just to the acidic side of a 50,000-MW phosphoprotein present in uninfected cells (pp50). Although pp50A is not found in uninfected cells (Fig. 1*b*), cells transformed by the SR-A strain of RSV appear to contain both pp50A and pp50B (Fig 1*d*). Identical results were obtained using the Prague, B77 and Bryan strains of RSV; transformation-defective deletion mutant virus-infected cell lysates contained pp50B alone. These observations suggest that pp50A might arise by RSV-induced phosphorylation of pp50B. Indeed, charge calibration of these gels by forced carbamylation[11] indicated a difference of one charge unit between pp50A and pp50B, which at this *p*H could be accounted for by a difference of one phosphate group.

To investigate further the possible relationship between pp50A and pp50B, these ^{32}P-labelled proteins were excized from two-dimensional gels and analysed by partial proteolysis with chymotrypsin, using the method of Cleveland *et al.*[12] (Fig. 2). Several other 50,000-MW phosphoproteins migrating at more basic *p*H than pp50B were also analysed (Fig. 2, upper panel; pp50C, D and E). pp50B from uninfected cells or cells transformed by the SR-A or Bryan strains of RSV had the same cleavage pattern, consisting of two major phosphopeptides (Fig. 2, lower panel). pp50A from cells transformed by either strain of RSV, and isolated by either two-dimensional gel electrophoresis or immunoprecipitation with TBR serum, yielded two phosphopeptides co-migrating with those of pp50B plus two new phosphopeptides (indicated in Fig. 2 by asterisks). The pp50C, D and E spots do not seem to be related to pp50A and B by this type of analysis, although we have not rigorously ruled out such a relationship. These data suggest that pp50A and B represent different phosphorylated forms of the same protein, pp50A being formed by the transformation-dependent phosphorylation of pp50B at a new site(s).

To determine whether phosphorylation of pp50 on tyrosine[6] is transformation dependent, the phosphoamino acid contents of pp50A and B were analysed (Fig. 3). The pp50B species from either uninfected (lane 1) or RSV-transformed (lane 2) cells contains only phosphoserine. The transformation-specific pp50A species contains phosphotyrosine in addition to phosphoserine (lane 3). This observation, combined with the phosphopeptide analysis described above, suggests that the difference in migration of the pp50A and B species during isoelectric focusing is due to an additional phosphate group bound to a tyrosine residue on pp50A.

The observation that pp50 is present in both uninfected and RSV-transformed cells, but is phosphorylated on tyrosine only in the latter, suggested that pp50 may be a substrate for pp60$^{\mathrm{src}}$. To test this hypothesis further, we examined whether the tyrosyl phosphorylation of pp50 was temperature sensitive in chicken cells infected with the NY68 strain of RSV[13], which contains a ts

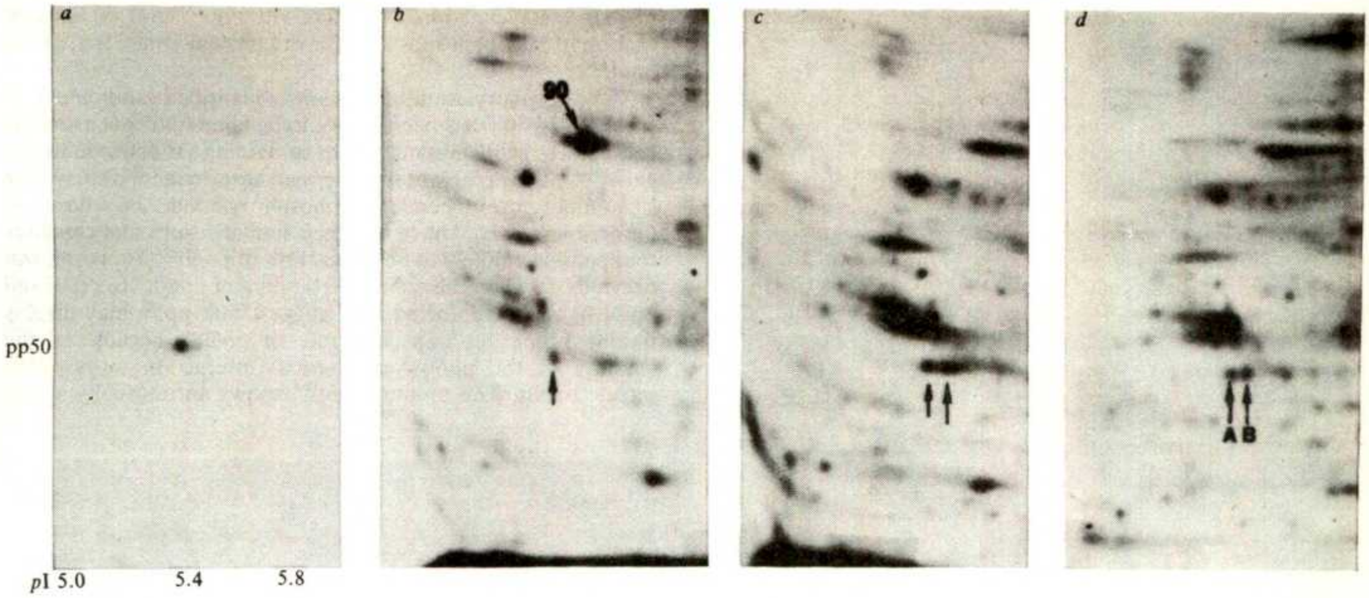

Fig. 1 Two-dimensional analysis of phosphoproteins from normal and RSV-transformed chicken cells. Samples for analysis on two-dimensional gels were prepared as described below. Immunoprecipitated proteins. Chicken cells (1×10^6) transformed by the SR-A strain of RSV were labelled for 4 h with 1 mCi ml^{-1} ^{32}P-orthophosphate in phosphate-free medium. Cell lysates were prepared as described previously[1] using RIPA buffer (150 mM NaCl, 1% Triton X-100, 1% sodium deoxycholate, 0.1% SDS, 10 mM Tris-HCl *p*H 7.2) with 5 mM EDTA. The clarified lysates were incubated with 30 μl of TBR serum for 20 min and then formalin-fixed *Staphylococcus* bacteria[21] were added for 10 min. The washed bacteria were incubated with 30 μl of OFLB (9.5 M urea, 2% NP-40, 5% β-mercaptoethanol, 0.4% ampholytes (LKB) (*p*H 3.5–10), 1.6% ampholytes (LKB) (*p*H 5–7) at 22 °C for 10 min. The bacteria were then removed by centrifugation and the supernatant frozen until ready for use. Total cell lysates. Normal or RSV-transformed (SRA strain) cells (1×10^6) were labelled for 4 h with 1 mCi ml^{-1} ^{32}P in phosphate-free medium. The cells were washed three times with STE (150 mM NaCl, 50 mM Tris-HCl *p*H 7.2, 1 mM EDTA) prepared according to a modification[22] of the O'Farrel method[23] for two-dimensional gel analysis of proteins. Briefly, the cells were incubated for 5 min in 300 μl of 2 mM CaCl, 20 mM Tris-HCl (*p*H 8.8) and 50 μg ml^{-1} *Staphylococcus* nuclease buffer (Boehringer-Mannheim). The cells were then forced through a 25 ga. needle, made up to 0.2% SDS, and 0.1 vol of DNase/RNase buffer (1 mg ml^{-1} DNase I (Sigma), 0.5 μg ml^{-1} RNase A (Sigma), 50 mM $MgCl_2$ and 0.5 M Tris-HCl *p*H 7.0) was added. The sample was quick-frozen, lyophilized and immediately resuspended in 180 μl of OFLB. Two-dimensional gels. Samples (15 μl) were loaded on to 0.2×16 cm cylindrical gels prepared as described elsewhere[23] with a 4:1 ratio of *p*H 5–7/*p*H 3.5–10 ampholytes (LKB). After prefocusing, the gels were run at 400 V, for 17 h, followed 800 V for 1.5 h. The gels were then removed from the tube and the gel section from 2–9 cm was equilibrated for 5 min in 2.5% SDS, 5% β-mercaptoethanol, 10% glycerol and 62.5 mM Tris *p*H 6.8, layered on to a 7.5% Laemmli[24] SDS-polyacrylamide gel and electrophoresed until the bromophenol blue reached the bottom of the gel. The gels were dried immediately and exposed to film for 16–24 h using a Lightning-plus (Kodak) intensifying screen. *a*, Phosphoproteins immunoprecipitated with TBR serum. (The pp60^{src} protein does not focus in this *p*H range and the faint spot around *p*I 5.6 is pp90). *b*, Phosphoproteins from normal chicken cells. (The spot designated 90 represents the protein which co-migrates with the pp90 immunoprecipitated protein). *c*, Phosphoproteins shown in *b* mixed with the proteins shown in *a*. *d*, Phosphoproteins from RSV-transformed chicken cells.

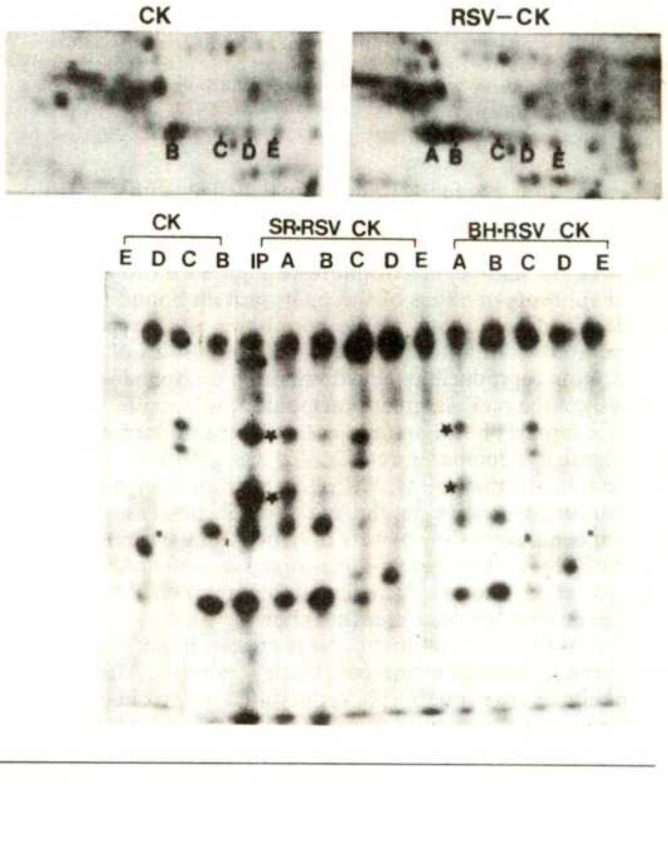

Fig. 2 Partial proteolytic digestion of the 50,000-MW proteins excized from two-dimensional gels. The gels of normal and RSV-transformed (SRA and BH strain) chicken cells were prepared as described in Fig. 1 legend. The upper panel identifies the ^{32}P-labelled RSV-transformed chicken cells (RSV-CK) re-electrophoresed (lower panel) on a 12.5% SDS-polyacrylamide gel with 500 μg ml^{-1} chymotrypsin (Sigma) according to the method of Cleveland *et al.*[12]. The gel was exposed for 1 week using intensification as described in Fig. 1 legend. The two-dimensional gel pattern of cells transformed by the Bryan (BH) strain of RSV was essentially identical to that of the SR-A strain shown in the upper panels. The lane designated IP contains the pp50 protein immunoprecipitated from ^{32}P-labelled RSV (SRA)-transformed cell lysates by TBR serum.

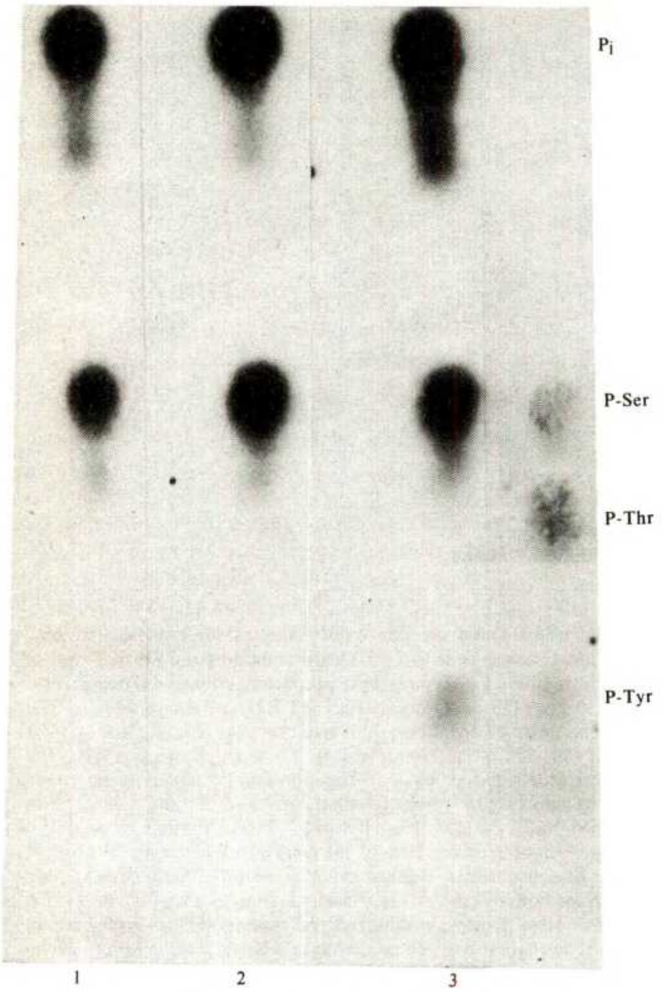

Fig. 3 Analyses of the phosphorylated amino acids associated with the pp50 proteins from normal and RSV-transformed chicken cells. The pp50A and B species were eluted from 12 two-dimensional gels of ^{32}P-labelled proteins from normal and RSV (SR-A) transformed cells prepared as described in Fig. 1 legend. The proteins were TCA-precipitated, acid-hydrolysed and electrophoresed at 4,000 V for 1.75 h in *p*H 3.5 buffer (pyridine/acetic acid/H_2O = 1 : 10 : 189) as described previously[25]. Lane 1, pp50B from normal chicken cells; lane 2, pp50B from RSV-transformed chicken cells; lane 3, pp50A from RSV-transformed chicken cells. Phosphoamino acid markers were co-electrophoresed with each radioactive sample. A representative ninhydrin-stained track is shown adjacent to the autoradiogram at the right of the figure for visualization of the marker amino acids (P-Ser, phosphoserine; P-Thr, phosphothreonine; P-Tyr, phosphotyrosine).

defect in the *src* gene. Cells were labelled with ^{32}P-orthophosphate at either 35 °C or 41 °C and the pp50 bound to pp60^{src} was isolated by immunoprecipitation with TBR serum followed by SDS-gel electrophoresis. Figure 4*a* shows that the tryptic phosphopeptides of the pp50 protein bound to pp60^{src} cannot be distinguished at the permissive and nonpermissive temperatures. Minor differences in the intensities of the spots were not reproducible. Furthermore, phosphoamino acid analysis of the pp50 immunoprecipitated with pp60^{src} indicated that the tyrosyl phosphorylation of pp50 was not reduced at the nonpermissive temperature (Fig. 4*b*). As a positive control, it was confirmed that the tyrosyl phosphorylation of pp60^{src} was temperature sensitive in the NY68-infected cells (Fig. 4*b*). Similar results (not shown) were obtained using the ts *src* mutant LA90[14]. In addition, two-dimensional gel analysis of cells labelled at 35 °C or 41 °C indicated the presence of the pp50A species at both temperatures (not shown).

Thus, we have found that pp50 is present in normal chicken cells as a phosphoserine-containing protein. After transformation by RSV, pp50 is phosphorylated on tyrosine as well as on serine. These results, coupled with the evidence that the protein is associated in a complex with pp60^{src} (ref. 8), suggest that pp50 may be a substrate for the protein kinase activity of pp60^{src}.

The phosphorylation of previously identified candidate substrates of pp60^{src} has been shown to be temperature sensitive in cells infected with mutant viruses containing a ts defect in the *src* gene[15–17]. The pp50 protein described here does not display such a temperature-dependent phosphorylation of tyrosine. Oppermann *et al.*[10] have obtained similar results and conclude that pp50 is unlikely to be a substrate of pp60^{src}. However, our previous data[8] on the enhanced binding of pp60^{src} to pp50 and pp90 in ts virus-infected cells suggest that pp50 may display unique properties as a substrate of pp60^{src} because of the stability of the pp60^{src}–pp90–pp50 interaction in ts virus-infected cells. The mutant pp60^{src} shows an unusually strong

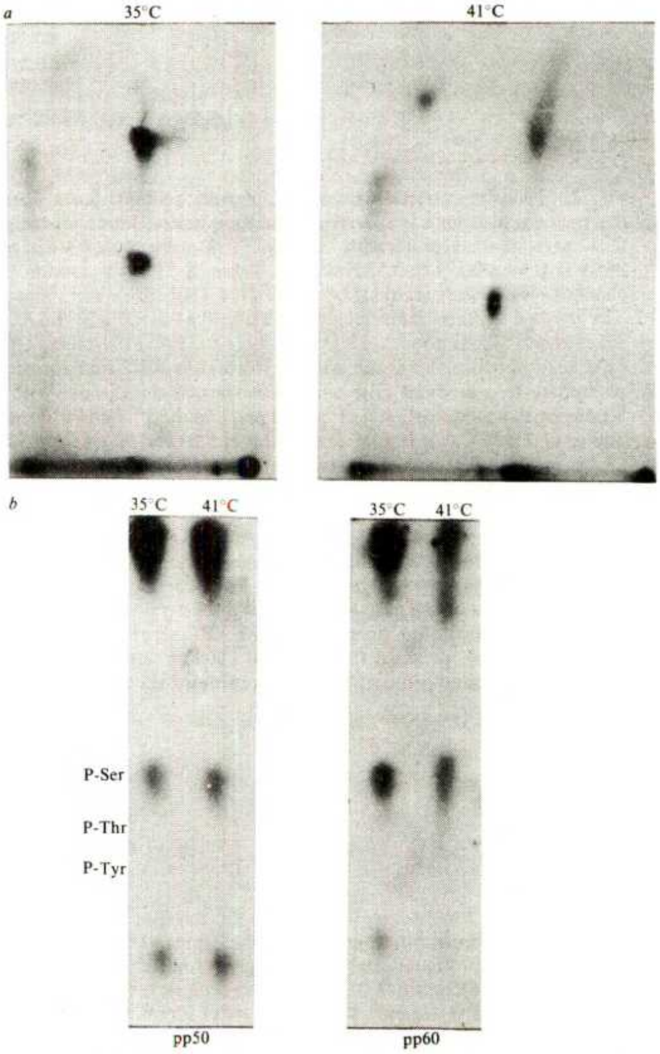

Fig. 4 Phosphopeptide and phosphoamino acid analysis of pp50 associated with pp60^{src} from cells transformed by a ts mutant RSV. Cells transformed by the RSV mutant, NY68 (ref. 13) were incubated at 35 °C or 41 °C for 24 h and subsequently labelled with ^{32}P (1 mCi ml^{-1} in phosphate-free medium) for 4 h. Cell lysates were prepared using RIPA and 5 mM EDTA, then clarified and immunoprecipitated with TBR serum as described in Fig. 1 legend. The immunoprecipitated proteins were electrophoresed on a 7.5% SDS-polyacrylamide gel and the pp50 and pp60 proteins eluted by incubation in 0.05 M ammonium bicarbonate and 0.1% SDS for 16 h. The proteins were then precipitated three times with 20% TCA, acetone-washed and split into two fractions. One half of the pp50 sample was oxidized with performic acid, trypsinized and electrophoresed at *p*H 6.0 as described previously[26]; the other half was hydrolysed in 6M HCl at 110 °C for 2 h, lyophilyzed and electrophoresed as described in Fig. 3 legend. *a*, Phosphopeptide analysis of pp50 from cells grown at 35 °C (left panel) and 41 °C (right panel). Chromatography was performed from right to left and electrophoresis, from bottom to top. The origin is in the lower right-hand corner of each autoradiogram. *b*, Phosphoamino acid analysis of pp50 (left panel) and pp60^{src} (right panel) from cells incubated at 35 °C and 41 °C. Marker phosphoamino acids were co-electrophoresed in each lane and visualized with ninhydrin.

interaction with pp50; up to 90% of mutant pp60^{src} is bound in a complex with pp50 and pp90, while at most 5% of wild-type pp60^{src} is found in this complex[8]. Furthermore, unlike the pp50–pp60^{src}–pp90 complex containing wild-type pp60^{src}, which turns over fairly rapidly, the complex containing mutant pp60^{src} is extremely stable; pulse-chase experiments indicate no detectable dissociation over a 5-h period (our unpublished data). The temperature insensitivity of pp50 phosphorylation might be explained by our previous observation that the binding of ts mutant pp60^{src} to pp50 is very stable at the nonpermissive temperature; thus, it is possible that pp60^{src} is able to phosphorylate pp50 in these conditions, although its ability to phosphorylate other substrates required for transformation is impaired[15–17].

The detection of the pp50A species after RSV infection does not seem to result from pp60^{src} binding to an unstable phosphotyrosine-containing form of pp50 present in the uninfected cell as variations in the amount of the pp50–pp60^{src}–pp90 complex in cells transformed by different strains of RSV were not reflected in the levels of the transformation-specific pp50A species. Although the pp50–pp60^{src}–pp90 complex was only minimally detectable in lysates of cells transformed by the Prague strain of RSV[8], the amount of pp50A species found in these lysates was similar to that found in lysates of cells, transformed by the SR-RSV strain, which contained at least 10-fold greater amounts of pp60^{src} bound to pp50 and pp90. These results suggest that formation of a stable complex between pp50 and pp60^{src} is not required for the detection of the phosphotyrosine-containing form of pp50. It also seems unlikely that pp50 is phosphorylated by a pp60^{src}-activated tyrosine-specific protein kinase as activation of other kinases would be expected to be temperature sensitive in cells infected with ts mutant viruses of RSV. Thus, we conclude tentatively that pp50 is a substrate for pp60^{src}; further testing of this hypothesis, by examining the ability of purified pp60^{src} to phosphorylate pp50 *in vitro*, awaits the purification of the pp50 species containing only phosphoserine (unpublished data).

We have recently obtained evidence that pp50 and pp90 are physically associated with the unrelated transforming proteins of Fujinami sarcoma[18,19] and Y73[20] viruses. Furthermore, we have found that the phosphotyrosine, phosphoserine-containing form of pp50 is detectable on two-dimensional gels of ^{32}P-labelled lysates from cells transformed by these viruses. This suggests that pp50 and pp90 may have a common interaction with transforming proteins which function as tyrosine-specific protein kinases.

During this study we learned that T. Gilmore, K. Radke and G. S. Martin have also demonstrated the presence of phosphoserine-containing forms of pp50 in uninfected chicken cells.

We thank Eileen White for assistance with gels and Mike Chinkers and David Gates for comments on the manuscript. We also thank Jean Altwein and Sandi Donaldson for secretarial help. This work was supported by NIH grant CA27951-01.

Endogenous MuLV infection does not contribute to onset of radiation- or carcinogen-induced murine thymoma

Allen Mayer & Karoline Dorsch-Häsler

Department of Pathology, New York University School of Medicine,
550 First Avenue, New York, New York 10016, USA

T-cell lymphoma can be induced in mice by experimental infection with certain strains of murine leukaemia virus (MuLV) or by the action of germ-line transmitted endogenous MuLV[1]. B-cell lymphomas are induced in chickens by inoculation with certain strains of exogenous avian leukosis virus[2]. These systems have two common features: a requirement for actively replicating retrovirus, and a long latency period between introduction or appearance of the virus and development of the tumour. Such features are consistent with models of transformation that require multiple rounds of infection either to activate cellular oncogenes by promoter insertion[3] or to generate recombinant retrovirus genomes that have novel leukaemogenic activity[4]. The development of T-cell lymphoma in mice exposed to radiation or chemical carcinogens is also marked by a lengthy latency period between exposure to radiation or carcinogen and outgrowth of the tumour, and leukaemogenic MuLV is frequently isolated from tumour tissue[5,6]. We show here, however, that active infection of cells by endogenous MuLV is not essential to the development of thymic lymphoma in the mouse following exposure to radiation or chemical carcinogens.

The germ lines of all inbred mouse strains contain multiple copies of MuLV sequences, hence the designation endogenous MuLV[1,7]. A subset of these sequences can be expressed as infectious virus with an ecotropic (mouse-infectious) host range. Relative susceptibility to infection of mouse cells by ecotropic MuLV is regulated by alleles at the cellular *Fv-1* locus[8]. Differing alleles at the *Fv-1* locus, designated *n* and *b*, divide inbred mouse strains into two groups, N-type mice and B-type mice, cells of N-type mice being more susceptible to infection by N-tropic MuLV and those of B-type mice more susceptible to B-tropic MuLV infection. As *Fv-1*-mediated restriction to infection is a dominant phenotype, mice carrying both an *Fv-1*^{n} and an *Fv-1*^{b} allele are relatively restrictive for infection by both N-tropic and B-tropic MuLV[8].

Genetic analysis of the effect of the *Fv-1*^{b} allele on the incidence of lymphoma in the high incidence AKR inbred mouse strain showed that active infection of somatic cells by endogenous MuLV was required for the development of spontaneous thymic lymphoma[9]. AKR mice carry an *Fv-1*^{n} allele, and express N-tropic MuLV to high titres. When AKR mice were crossed to mice of the low lymphoma incidence BALB/c strain (homozygous for the *Fv-1*^{b} allele), both lymphoma incidence and infectious MuLV titre were much lower in F_1 hybrids than in the AKR parent. Suppression of both MuLV expression and spontaneous thymic lymphoma was associated in mice of the (BALB/c × AKR)F_1 × AKR backcross, indicating that the segregating *Fv-1*^{b} allele coordinately suppressed both traits in a genetically dominant fashion.

A similar experiment described here tested the effect of *Fv-1* on the development of radiation-induced thymic lymphoma, to determine whether this form of induced thymoma also requires active MuLV infection. As shown in Fig. 1*a*, both the RF/J and BALB/cJ strains are highly susceptible to radiation induction of

0028–0836/82/030253—03$01.00

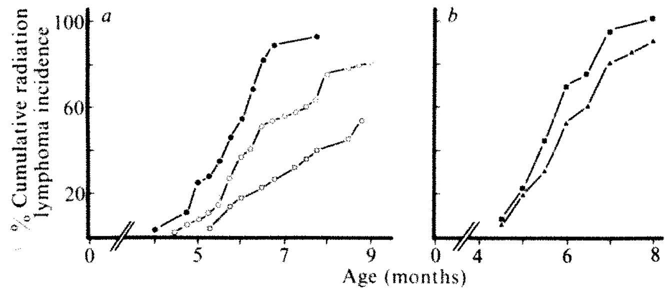

Fig. 1 Cumulative radiation-induced thymic lymphoma incidences in various populations of mice. Female mice were exposed to four weekly doses of 160 rad of γ-ray irradiation[5] (Gammator M ^{137}Cs source, Radiation Machinery Corporation, 530 rad min^{-1}), beginning at 33 ± 3 days old. Mice were checked daily for signs of lymphoma, including laboured breathing and enlarged peripheral lymph nodes. Mice displaying these symptoms were killed so as to detect the grossly enlarged thymus characteristic of this neoplasia. *a*, Populations of 28 RF/J mice (●—●), 22 BALB/cJ mice (□—□) and 52 (BALB/c × RF)F$_1$ hybrid mice (○—○); *b*, two subpopulations of (BALB/c × RF)F$_1$ × RF backcross mice, according to *Fv-1* type. 48 *Fv-1*^{n} homozygous mice (■—■) and 35 *Fv-1*^{n}/*Fv-1*^{b} heterozygous mice (▲—▲). *Fv-1* typing was accomplished by typing individual mice for their alleles at the closely linked *Gpd-1* locus[11], according to the procedure of Ruddle *et al.*[12].

thymoma, but RF mice display a shorter latency of tumour development. RF mice carry an *Fv-1*^{n} allele and express N-tropic MuLV, whereas BALB/c mice carry the *Fv-1*^{b} allele and can express both N-tropic and B-tropic MuLV[10]. If infectious spread of these MuLVs promotes development of radiation-induced thymoma in their respective strains, the (BALB/c × RF)F$_1$ hybrid would be expected to show a lower incidence of radiation-induced thymoma than either parental strain, because the RF-derived *Fv-1*^{n} allele will restrict infection of F$_1$ cells by the BALB/c B-tropic MuLV, while the BALB/c-derived *Fv-1*^{b} allele will restrict infection of F$_1$ cells by the RF N-tropic MuLV. Despite this genetic restriction on virus infection, F$_1$ hybrids showed a high incidence of radiation-induced thymoma, with a latency intermediate between that of the two parental strains (Fig. 1*a*), thus indicating that restrictive *Fv-1* alleles do not suppress development of radiation-induced thymoma.

To measure the effect of *Fv-1* in this cross more directly, the incidence of radiation-induced thymoma was determined in (BALB/c × RF)F$_1$ × RF backcross mice typed for the alleles they carried at the *Fv-1* locus. *Fv-1*^{n} homozygous and *Fv-1*^{n}/*Fv-1*^{b} heterozygous backcross mice were identified by typing each backcross mouse for its phenotype at the *Gpd-1* locus, which is closely linked to the *Fv-1* locus (<1% recombination between the two loci)[11]. The differing electrophoretic mobilities of the glucose-6-phosphate dehydrogenases specified by the *Gpd-1*^{a} and *Gpd-1*^{b} alleles (of RF and BALB/c, respectively)[12] served to distinguish *Gpd-1*^{a} homozygotes (*Fv-1*^{n} mice) from *Gpd-1*^{a}/*Gpd-1*^{b} heterozygotes (*Fv-1*^{n}/*Fv-1*^{b} mice) in the backcross. Figure 1*b* shows that these two subpopulations of the backcross did not differ substantially in their radiation-induced thymoma incidences, confirming that *Fv-1* does not suppress the incidence of this lymphoma.

These findings are not consistent with a requirement for active infection by endogenous MuLV in the development of radiation-induced thymoma. Cellular infection by both ecotropic[8] and dualtropic MCF-type MuLVs[13] are sensitive to *Fv-1* restriction, and the leukaemogenic activity of endogenous MuLV is strongly inhibited by a restrictive *Fv-1* genotype[9] yet here no corresponding strong suppression of radiation lymphoma by *Fv-1* was observed.

When the backcross mice were typed for their haplotype at *H-2*, the major histocompatibility complex of the mouse, no *H-2*-associated effect was observed to influence relative resistance to radiation-induced thymoma. An absence of *Fv-1* and *H-2* influences on thymoma incidence as induced by the chemical carcinogen 3-methylcholanthrene has previously been reported in the I/LnJ × RF cross[14].

We further assessed the contribution of endogenous mouse-infectious MuLV to the development of radiation- and carcinogen-induced thymoma. If infectious MuLV is indeed aetiologically involved in these induced lymphomas, one would expect to observe association between susceptibility to induced thymoma development and the segregation in appropriate genetic crosses of those murine genes that code for mouse-infectious MuLV. The 129 × RF cross was chosen for study because RF mice express endogenous ecotropic MuLV[15] but 129 mice have never been observed to do so[16]. Although 129 mice contain multiple copies of endogenous MuLV genes[7], and indeed express virus-coded antigens *in vivo*[17], their DNA lacks a specific portion of the endogenous ecotropic MuLV genome[16] and hence complete infectious ecotropic MuLV is not elaborated in 129 tissue. Furthermore, we have observed that RF mice contain a single locus governing iododeoxyuridine (IUdR)-induction of XC-detectable ecotropic MuLV. Such loci are thought to represent structural genomes of endogenous MuLV[18]. The conclusion that RF mice carry a single replication-competent ecotropic MuLV genome was reached by *in vitro* IUdR treatment of cultures of tail explant fibroblasts obtained from individual mice of the (129 × RF)F$_1$ × 129 backcross, followed by detection of MuLV production by these cells using

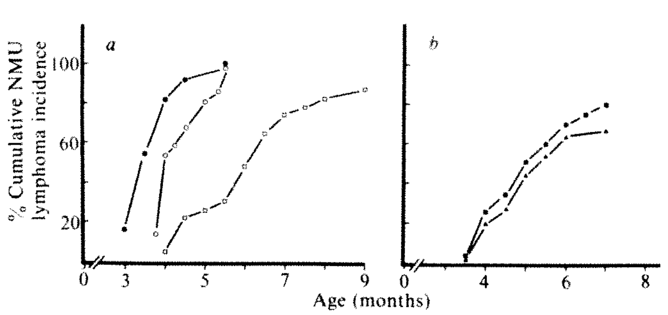

Fig. 2 Cumulative nitrosomethylurea-induced thymic lymphoma incidences in various populations of mice. Female mice were injected weekly with NMU (2 mg ml^{-1} in SSC, 30 mg per kg body weight) intraperitoneally for 5 consecutive weeks, beginning at 5 weeks of age[23]. Development of lymphoma was monitored as described in Fig. 1 legend. *a*, Populations of 39 RF/J mice (●—●), 23 129/J mice (□—□), and 23 (129 × RF)F$_1$ hybrid mice (○—○); *b*, two subpopulations of the (129 × RF)F$_1$ × 129 backcross, 71 mice containing an IUdR-inducible, XC-detectable ecotropic MuLV genome (■—■), and 61 mice lacking this MuLV genome (▲—▲).

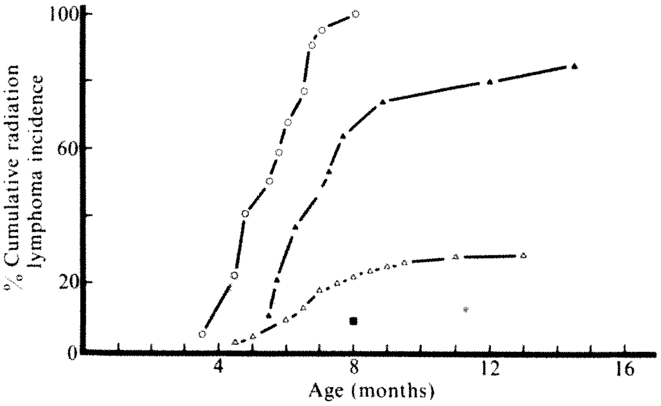

Fig. 3 Cumulative radiation-induced thymic lymphoma incidences in various populations of mice. Female mice were exposed to γ-ray irradiation and monitored for development of thymic lymphoma as described in Fig. 1. legend. 22 RF/J mice (○—○), 11 129/J mice (■—■), 19 (129 × RF)F$_1$ hybrid mice (▲—▲) and 197 (129 × RF)F$_1$ × 129 backcross mice (△—△). Only one of the eleven 129/J mice developed thymoma, and thus this result is presented as a single point.

the XC assay[19]. This procedure has been described by Lander *et al.*[20], and detects the presence of ecotropic MuLV in all RF and $(129 \times RF)F_1$ mice, but not in 129 mice. In a population of $(129 \times RF)F_1 \times 129$ backcross mice, tail cultures from 72 of 132 mice tested were virus-positive, demonstrating the segregation of a single RF-derived ecotropic MuLV locus in the cross. Note that this assay says nothing about the manner or quantity of expression *in vivo* of ecotropic MuLV in the mice tested. It merely detects the presence of a replication-competent ecotropic MuLV genome while allowing individual mice to be tested concomitantly for radiation and carcinogen-induced thymoma development. In contrast to the BALB/c × RF cross described above, RF and 129 mice do not differ with respect to their *Fv-1* genotype[8], and RF ecotropic MuLV expression will not be restricted in this cross as compared with the parental RF strain.

Figure 2*a* shows that both RF and 129 mice are highly sensitive to induction of thymoma by the chemical carcinogen *N*-nitrosomethylurea (NMU), and that RF mice display a shorter latency of tumour development than do 129. F_1 hybrid mice have an intermediate latency. The high incidence of NMU-induced thymic lymphoma in the 129 strain, albeit at later ages than RF, in itself demonstrates that cellular infection by ecotropic MuLV is not required for the development of this induced lymphoma, because, as mentioned above, 129 mice lack this viral activity. When the incidence of NMU-induced thymoma was compared in $(129 \times RF)F_1 \times 129$ backcross mice either carrying or lacking a replication-competent ecotropic MuLV genome, as typed by IUdR induction of tail explant fibroblast cultures followed by detection of MuLV expression using the XC plaque assay[20], the two subpopulations of the backcross showed virtually identical incidences (Fig. 2*b*). This indicates that the RF ecotropic MuLV locus detected here does not seem to be a major determinant in the short latency of NMU-induced thymic lymphoma in RF mice.

Figure 3 shows that RF mice are much more sensitive to radiation-induced thymoma than are 129 mice, and that F_1 hybrid mice also develop a high incidence of this tumour. A population of $(129 \times RF)F_1 \times 129$ backcross mice was exposed to radiation (Fig. 3), and backcross mice that developed thymic lymphoma were randomly tested for the presence of the RF IUdR-inducible ecotropic MuLV locus. Only 22 out of 37 lymphomatous backcross mice tested were seen to carry the RF ecotropic MuLV locus, a result not significantly different from that expected from random segregation of this locus in the lymphomatous population, and indicating that the locus is not a major factor in determining susceptibility to radiation-induced lymphoma.

These findings point to a basic difference between the aetiologies of spontaneous and carcinogen- or radiation-induced thymoma. The spontaneous occurrence of this tumour is associated with expression of endogenous mouse-infectious MuLV activities, including both XC-positive[9] and XC-negative[21] ecotropic MuLVs and dualtropic MCF MuLV[13]. The present data indicate that both carcinogen- and radiation-induced thymoma develop in the absence of replication-competent XC-positive ecotropic MuLV activity. The dependence of spontaneous thymoma development on actual infectious events has been previously indicated by its marked susceptibility to suppression by a restrictive *Fv-1* allele[9]. In contrast, neither carcinogen- nor radiation-induced thymoma development is sensitive to suppression by *Fv-1*. This indicates that those infectious viral events that are aetiologically involved in development of spontaneous thymomas are not required for the development of induced thymomas. Finally, note that the possible importance to the development of induced thymomas of endogenous MuLV antigen expression in the absence of infectious virion production[22] has not been addressed here, and remains a viable hypothesis.

Altered methylation of endogenous viral promoter sequences during mammary carcinogenesis

Trudy Breznik & J. Craig Cohen

Department of Microbiology and Immunology, Tulane University,
School of Medicine, New Orleans, Louisiana 70112, USA

Mouse mammary tumour virus (MMTV) is a type B retrovirus that may be transmitted either by somatic cell infection via infectious virus borne in mother's milk or vertically by passage of virus-specific sequences in the germ line. Endogenous viral sequences act as stable genetic loci[1] and are found in all inbred mouse strains studied. Available data suggest that, in general, strains exhibiting only endogenous virus have a low tumour incidence whereas a high tumour incidence occurs in strains carrying milk-borne MMTV, in addition to germ-line sequences. However, as removal of the milk-borne virus does not completely eliminate tumours, endogenous proviral sequences may also be involved in tumorigenesis[2–4]. Recent results have shown that proviral sequences acquired from milk are undermethylated (low 5-methylcytosine content), whereas endogenous MMTV sequences are highly methylated. An inverse relationship between proviral methylation and transcriptional activity has also been demonstrated[5,6]. This model suggests that an important mechanism of MMTV-induced tumorigenesis in uninfected mice (those lacking milk-borne MMTV) may involve derepression of endogenous proviruses, possibly through demethylation of these sequences. Here we show that the methylation pattern of endogenous virus sequences is specifically altered during tumorigenesis in uninfected mice.

Several tumours occurring in BALB/c mice were studied both for the acquisition of new MMTV proviral sequences and for demethylation of endogenous viral sequences. As tumours occur infrequently in this strain, those derived from the D1 series of hyperplastic outgrowth lines developed by Medina[7] were used. These tissues (supplied by R. Cardiff) are transplantable and are analogous to the pre-neoplastic nodules commonly seen in the mammary gland. Outgrowth lines are

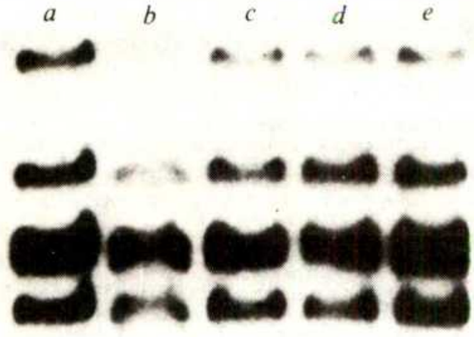

Fig. 1 *Eco*RI digestion of DNA for liver and mammary tumours of the BALB/c mouse strain. DNA was extracted by placing tissue in DNA extraction buffer (0.2 M Tris-HCl *p*H 8.1, 0.01 M EDTA *p*H 7.0, and 0.1 M NaCl) and homogenized using a motor driven, Teflon-glass Dounce homogenizer. Protein was removed by incubation at 37 °C for 12 h with proteinase K (100 g ml^{-1}) and SDS (1%) followed by phenol–chloroform (2 : 1) extraction. DNA was spooled on to a glass rod by addition of 0.2 M sodium acetate and two volumes of cold ethanol. DNA was resuspended in 0.005 M Tris-HCl *p*H 7.4 and 0.1 mM EDTA *p*H 7.0 and concentration determined by UV absorption. Each sample (10 μg) was digested to completion by *Eco*RI (12-fold excess) as determined by using λ bacteriophage DNA as an external control. Samples were electrophoresed in 0.8% agarose in a buffer containing 0.02 M sodium acetate *p*H 7.0, 0.018 M NaCl and 0.002 M EDTA. Bromophenol blue was used as a tracking dye which was electrophoresed 20 cm. ^{32}P-labelled, *Hin*dIII-digested λ bacteriophage DNA was run in parallel as a molecular weight marker. Following electrophoresis DNA was transferred to nitrocellulose sheets (Schleicher & Schuell) by the method of Southern[11] using modifications as described previously[5]. Virus-specific bands were detected by hybridization with ^{32}P-labelled, representative, complementary DNA (cDNArep) synthesized using calf thymus primers to initiate DNA synthesis by reverse transcriptase on a cloned MMTV DNA template. The hybridization buffer included 50% formamide, Denhardt's buffer[11], 20 g ml^{-1} salmon sperm DNA, 0.05 M HEPES buffer *p*H 7.0, and 3 × SSC (SSC = 0.15 M NaCl, 0.015 M Na citrate). After hybridization at 41 °C for 48 h, filters were washed as described previously[5] and bands detected by autoradiography using Kodak XAR-5 X-ray film with Cronex Lightning Plus intensifying screens at −70 °C. *Eco*RI was used to digest DNA from BALB/c liver (lane *a*), D1 mammary tumours 997, 968 and 599 (lanes *b–d*, respectively) and the transplanted mammary tumour 1247 (lane *e*). Molecular weight in kilobases was determined by inclusion of *Hin*dIII-digested λ bacteriophage DNA (not shown).

transplanted into young females along with pituitary isografts to facilitate tumour development.

Virus-specific sequences were detected using the method of Southern[8] following digestion of DNA with *Eco*RI, which has a single restriction site within the full-length MMTV genome. Therefore, cleavage by this enzyme generates from each provirus two virus-specific fragments whose sizes depend on the integration site of the virus in the host genome (thus, fragment length is determined by the nearest *Eco*RI site in cellular DNA). Using this technique we determined that BALB/c mice contain three endogenous MMTV proviruses, designated units I, II and III; units II and III are full length and unit I is subgenomic.

Figure 1*a* is an *Eco*RI digest of uninfected liver[9] DNA, showing the five previously mapped endogenous virus-specific fragments which range in size from 6.7 to 16.7 kilobases (kb). Unit I is included in the 16.7-kb fragment, unit II in fragments of 8.5 and 7.0 kb and unit III in the 10.0- and 7.8-kb fragments. Examination of DNA from BALB/c tumours (Fig. 1*b–e*) reveals virus-specific fragments identical to those found in liver DNA. Because mammary tumours are clonal[10] and acquisition of MMTV proviruses is known to be a random event in the mouse genome[1], the failure to find additional *Eco*RI fragments whose size is dependent on site of integration (see above and ref. 11) indicates that only the genetically transmitted viral sequences are present. Therefore, infection and re-integration of MMTV DNA, although facilitating mammary carcinogenesis, is not essential.

The level of 5-methylcytosine in virus-specific sequences was probed using the restriction enzymes *Msp*I and *Hpa*II, isoschizomers which recognize the sequence 5′CCGG. Because *Msp*I will cleave this sequence regardless of methylation of the internal cytosine residue, while *Hpa*II is inhibited by methylation at this site[5,12], digestion of cellular DNA with these enzymes differentiates methylated from non-methylated sites. Figure 2 shows *Msp*I and *Hpa*II digestion of BALB/c liver and D1 tumour DNAs. *Msp*I digestion of liver DNA (Fig. 2*a*) generates a series of virus-specific fragments of 0.2–8.4 kb (ref. 5). *Hpa*II-cleaved BALB/c liver DNA, on the other hand, demonstrates extensive methylation of all viral fragments, as evidenced by the single high molecular weight (>15 kb) virus-specific fragment. *Hpa*II digestion of D1 tumour DNAs (Fig. 2*d*, *f*, *h*), however, generates two virus-specific bands of 2.1 and 1.4 kb. Therefore, sites in MMTV proviruses methylated in DNA from both uninfected liver and lactating mammary gland (Fig. 2*b*, and ref. 5) are demethylated during mammary carcinogenesis in the BALB/c mouse strain.

We determined the origin of the 2.1- and 1.4-kb *Hpa*II fragments by comparing *Msp*I digests from various inbred mouse strains, as MMTV proviral units vary between different strains[1]. Comparison of the previously published[5] *Msp*I digestion of DNA from the CBA/CaJ mouse strain (which includes units II and III) with that obtained with DNA from BALB/c (which includes units I, II and III), indicated that the 2.1- and 1.4-kb *Msp*I–*Hpa*II fragments are derived from the subgenomic unit I.

*Hpa*II digestion of DNA from BALB/c mammary tumour 1247 (not shown) produced several virus-specific fragments in addition to those derived from unit I, indicating that demethylation of other endogenous proviruses has occurred in this tumour. The origin of these additional sites of demethylation in tumour 1247 was identified by *Eco*RI–*Hpa*II double digestions. By determining which *Eco*RI bands are sensitive to further cleavage by *Hpa*II, one can ascertain the proviral units being demethylated during tumorigenesis (Fig. 3). This is possible in the BALB/c strain because all *Eco*RI fragments are mapped to specific units of MMTV proviral DNA[9].

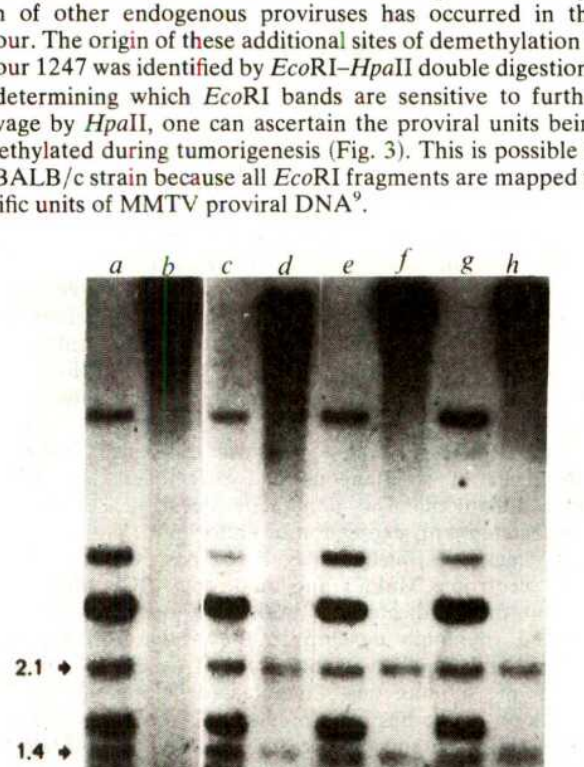

Fig. 2 Methylation of MMTV sequences in BALB/c liver and mammary tumours. DNA from either liver (lanes *a*, *b*) or D1 mammary tumours (lanes *c–h*) were digested with either the methyl-insensitive isoschizomer *Msp*I (lanes *a*, *c*, *e*, *g*) or methyl-sensitive *Hpa*II (lanes *b*, *d*, *f*, *h*) and virus-specific bands analysed as described in Fig. 1. legend.

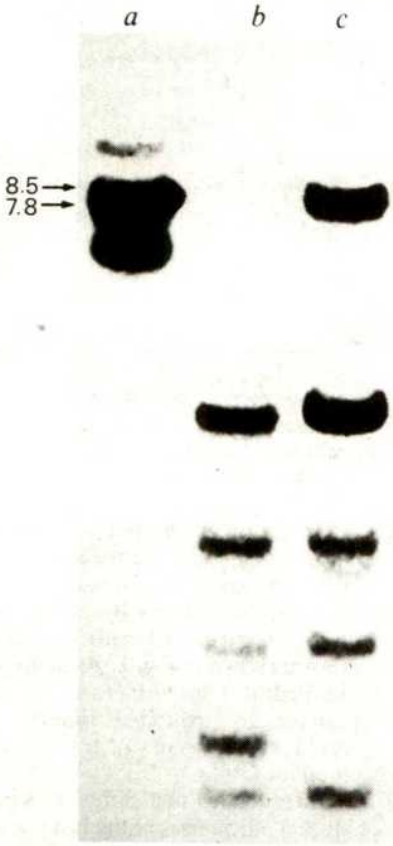

Fig. 3 Characterization of demethylated sequences in mammary tumour 1247. DNA from tumour 1247 was digested with either *Eco*RI (lane *a*) or sequentially with *Eco*RI and either *Msp*I (lane *b*) or *Hpa*II (lane *c*) and virus-specific fragments were detected as described in Fig. 1. legend.

Cleavage of MMTV-specific *Eco*RI fragments by the methyl-insensitive isoschizomer *Msp*I (Fig. 3*b*) indicates the presence of *Msp*I–*Hpa*II sites in all fragments. Double digestion with *Eco*RI and *Hpa*II (Fig. 3*c*) reveals demethylation of specific proviral sequences. The 8.5- and 7.8-kb fragments remain methylated as evidenced by their presence in the *Eco*RI–*Hpa*II double digestion. The 16.7, 10.0- and 6.7-kb *Eco*RI fragments, however, are demethylated because, whereas *Msp*I–*Hpa*II sites in BALB/c liver are highly methylated, resulting in no cleavage of any *Eco*RI fragments by *Hpa*II (data not shown), tumour 1247 showed a specific loss of methylated bases from these three fragments. Previous data[9] mapping restriction endonuclease sites on the endogenous MMTV proviruses of BALB/c mice revealed that the 8.5- and 7.8-kb *Eco*RI fragments are derived from the 5′ ends of units III and II, respectively. Two of the remaining three *Eco*RI fragments (10.0 and 6.7 kb) which are cleaved by the methyl-sensitive *Hpa*II are derived from the 3′ ends of units II and III. The 16.7-kb *Eco*RI fragment is obtained from the subgenomic, 3′ sequence containing unit I. Thus, spontaneous BALB/c tumours studied show the specific demethylation of virus-specific sequences derived from the 3′ region of the viral genome. Recent sequencing data[13] indicate the presence of *Hpa*II cleavage sites in the long terminal repeats (LTRs) of several MMTV proviruses which seem to be identical to units II and III. The demethylation event occurring in tumour 1247 is thus extremely specific, as it distinguishes between two direct repeats occurring at each end of these two proviruses[9]. The significance of these additional demethylation events in tumorigenesis of this particular tumour is unclear, because in other tumours demethylation of only unit I was observed.

Previous studies[14–16] have indicated that, at each end of retroviral DNA, sequences from the 3′ end of the viral genome are repeated along with a short sequence from the 5′ region. In MMTV this LTR is 1,200 base pairs long and contains an open reading frame capable of encoding[13] a protein of molecular weight 38,000. As hypomethylation correlates with gene expression, the demethylation observed in these spontaneous BALB/c tumours may represent activation of this gene. However, no protein derived from this open reading frame has been identified.

Another possible explanation for the specific demethylation of these sequences during mammary carcinogenesis involves promoter activation. The promoter for transcription of the retroviral genes apparently resides in the 3′ sequences of the LTR[17,18], and it has been suggested that carcinogenesis occurs through a mechanism of cell transformation referred to as oncogenesis by promoter insertion, that is, that the introduction of the viral promoter (in the LTR) allows transcription of cellular sequences associated with the 3′ end of the provirus. The present results suggest that in addition to transformation by promoter insertion that may occur during exogenous MMTV infection, carcinogenesis by promoter derepression may occur. This is supported by the observed demethylation of either the defective MMTV sequence (unit I) or specifically the 3′ half of the nondefective proviruses (units II and III), as decreased levels of methylation are known to correlate with increased transcriptional activity of MMTV[5,6] and other eukaryotic genes[19,20].

High frequency of gene transfer after fusion between bacteria and eukaryotic cells

Minoo Rassoulzadegan, Bernard Binetruy & François Cuzin

Centre de Biochimie du CNRS, Université de Nice, Parc Valrose,
06034 Nice, France

Recent studies[1] have demonstrated that eukaryotic simian virus 40 (SV40) genes carried in a bacterial plasmid can be directly transferred into mammalian cells in culture; after polyethylene glycol (PEG)-induced fusion with bacterial protoplasts, a fraction of the recipient cells yielded infectious virus. We have now investigated whether this procedure can also produce stable transformants. We report here that the efficiency of focus formation after transfer of either polyoma virus or SV40 early genes was at least equal to that observed after infection with virions. At high ratios of bacteria/recipient cells, all the cells were observed to express the early viral proteins 48 h after fusion. In optimal conditions, transfer by fusion thus seems to be 10- to 20-fold more efficient than DNA transfection by the Ca^{2+} co-precipitation technique[2] for the introduction of foreign genes into eukaryotic recipients.

0028-0836/82/030257—03$01.00

Escherichia coli (strain 1106; ref. 3) carrying one of the plasmids listed in Table 1 were grown to a density of 2×10^8 cells per ml. Chloramphenicol was added at a final concentration of 200 μg ml^{-1} and the cultures were aerated overnight. Aliquots (10 ml) were centrifuged and the bacteria resuspended at 0 °C in 100 μl of 50 mM Tris-HCl buffer, *p*H 8.0, containing 20% sucrose; 20 μl of a freshly made solution of lysozyme (10 mg ml^{-1}; Boehringer) were added and the suspension incubated at 0 °C for 10 min. After addition of 50 μl of 0.25 M EDTA, the suspension was diluted by progressive addition of 1.3 ml of 50 mM Tris-HCl buffer, pH 8.0, containing 9% sucrose. Microscopic examination indicated that >90% of the bacteria were converted into protoplasts. The recipient cells were grown in Dulbecco's modified Eagle's medium (DMEM, Gibco) in 35-mm Petri dishes to a density of 2×10^5 cells per plate. The medium was removed and the cells were washed once with 2 ml of Tris-buffered saline solution, 2 ml of the protoplast suspension were added to the plates and centrifuged onto the cell layer (1,500 r.p.m. for 3 min). The supernatant was removed and 0.5 ml of a 48% solution of PEG 1,000 in DMEM (48 g PEG dissolved in 52 g DMEM) was added. After 1 min at room temperature, the cells were washed carefully five times with Tris-buffered saline before being returned to the growth medium (DMEM supplemented with 10% newborn calf serum (Gibco)). The medium was changed on alternate days and the cultures were checked after 10 days for the appearance of foci.

As shown in Fig. 1, transformed foci were observed after fusion of FR3T3 rat cells[4] with bacteria carrying plasmid pPY-1. This plasmid includes a full-size wild-type polyoma virus genome recombined with pBR322 at the *Bam*HI site in the late viral region. No foci were produced after fusion with bacteria carrying an intact pBR322 plasmid, and results obtained with recombinants carrying various polyoma virus mutants were always in agreement with the known transforming ability of the viral genes present in the plasmid (Table 1): cleavage of polyoma virus DNA by recombination at the *Eco*RI site in the early region did not interfere with its transforming ability (plasmid pTS25E), as previously demonstrated after DNA transfection[5-7], whereas no transformants were produced using the cloned genome (pNG-1) of a transformation-defective *hrt* mutant[8]. The efficiency of focus induction was ~40 transformants per 2×10^5 cells at an input ratio of 10^4 protoplasts per cell (Fig. 1). Identical efficiencies were observed (data not shown) after fusion of protoplasts carrying either polyoma or SV40 early genes in pBR322 plasmid (plasmids pPY-1 and pSV-1; see Table 1) with both mouse and rat embryo fibroblasts in primary cultures, suggesting an equally high frequency of gene transfer. These values are comparable with those observed after infection of the same cells with high multiplicities of viral particles[4].

As 90–100% of the cells expressed the early proteins (T antigens) after virion infection, the relatively high efficiency of focus formation after fusion suggested a comparable high frequency of gene transfer. This frequency was measured directly by immunofluorescence determination on fixed cells after transfer of the early region of SV40 (plasmid pSV-1; see Table 1) into either permissive CV1 cells or non-permissive FR3T3 cells. Results are shown in Fig. 2. As many as 100% of CV1 nuclei were stained at a bacteria/recipient cell ratio of ~10^4. The dose–response curve exhibited a different slope in the case of FR3T3 rat cells, the efficiency of transfer being about one-half that observed for CV1.

Further studies are needed, as such differences between cell lines may reflect different efficiencies of the fusion process; they may reflect different efficiencies of expression after transfer of a given gene (for example, FR3T3 cells are non-permissive whereas CV1 cells are fully permissive for the development of SV40 virus). Frequencies of T-positive cells >50% were observed in FR3T3 cells at an input ratio of 3×10^4 bacteria per cell. It may be technically difficult to increase this ratio further, because a significant fraction of the cells are killed at very high bacteria/cell ratios.

The transfer frequencies observed were at least one order of magnitude higher than those after DNA transfection, which is

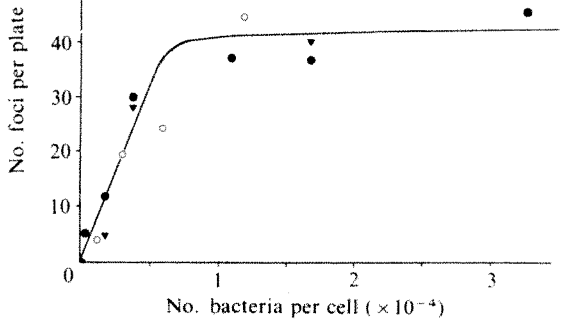

Fig. 1 Efficiency of focus formation after fusion of FR3T3 cells with bacteria carrying genomic polyoma virus DNA inserted in pBR322. Focus formation was measured as described in ref. 4. Abscissa, ratio of number of bacterial protoplasts to number of cells. Ordinate, number of foci per 35-mm Petri dish (2×10^5 cells). The different symbols represent results obtained in three separate experiments.

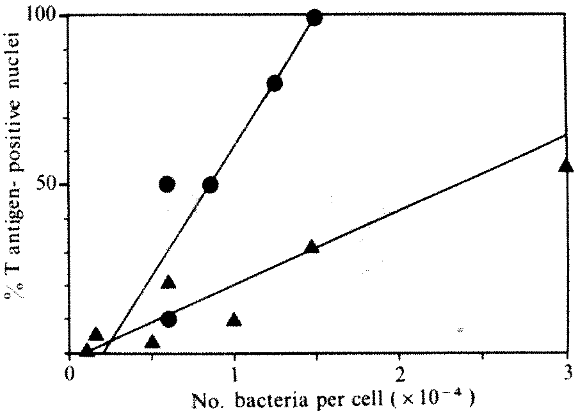

Fig. 2 Expression of the early viral antigens after fusion of FR3T3 (▲) and CV1 (●) cells with bacteria carrying SV40 early genes inserted in pBR322.

Table 1 Efficiency of focus formation after fusion with recipient cells of protoplasts carrying various viral DNA fragments in different plasmids

Plasmid	Viral DNA fragment	Insertion site in pBR322	Focus formation (foci per 2×10^5 cells)*
pBR322	None	—	0
pPY-1	Genomic polyoma DNA (wild-type A2 strain) cleaved at the *Bam*HI site	*Bam*HI	40
pTS25E	Genomic *tsa25E* polyoma DNA cleaved at the *Eco*RI site	*Eco*RI	25
pNG-1	Genomic polyoma *hrt* NG 18 mutant cleaved at the *Bam*HI site	*Bam*HI	0
pMC-2	Wild-type polyoma A2 sequences from *Bam*HI to *Eco*RI sites (distal parts of early and late genes)	*Eco*RI, *Bam*HI	0
pSV-1	Wild-type SV40 sequences from *Bam*HI to *Hpa*II sites (complete early region)	*Eco*RI	32

Plasmids pPY-1, pTS25E, pNG-1 and pMC-2 were constructed in our laboratory by the usual procedures (P. Clertant and M. Canning, unpublished results); plasmid pSV-1 is described in ref. 10 and was obtained from Dr C. Benoist. A2 strain polyoma DNA, see ref. 11; mutant *tsa25E*, ref. 12; mutant *hrt* NG 18, ref. 8.

* FR3T3 cells were fused with bacterial protoplasts as described in the text.

restricted to only a few 'competent' cells[9]. In our experiments, transfer of either polyoma or SV40 virus early genes by the Ca^{2+} co-precipitation technique produced 5–10% T antigen-positive cells at high doses of DNA (10 μg per 10^5 cells).

The frequency of T-positive CV1 cells after fusion was also 15- to 20-fold higher than that reported in comparable experiments[1]. A systematic analysis of the parameters involved (data not shown) indicated that the extent of lysozyme treatment was critical. As expected, incomplete conversion into protoplasts led to reduced frequencies of transformation. The same result was also observed, however, for prolonged lysozyme attacks which led to the lysis of a fraction of the protoplasts, apparent from the increased viscosity of the suspension. On the other hand, the chloramphenicol amplification step seems to be essential: in several cases where this step was omitted, using either pBR322 or pAT153 plasmid, no transformants were produced after fusion (data not shown). However, as these points were checked in previous experiments (W. Schaffner, personal communication), another important parameter that must be considered is the choice of bacterial strain. Although we cannot provide comparative data, it is possible that the strain used here (*E. coli* 1106) is more efficient than others, for example, *E. coli* HB101 (ref. 1), in producing stable protoplasts.

Biohazards associated with the experiments described here have been examined previously by the French National Committee and the experiments were carried out according to the rules established by this Committee.

Circular double-stranded RNA in potato spindle tuber viroid-infected tomatoes

R. C. French, M. A. Price & K. S. Derrick

Department of Plant Pathology and Crop Physiology,
Louisiana State University Agricultural Experiment Station,
Baton Rouge, Louisiana 70803, USA

Viroids are circular molecules of single-stranded RNA consisting of ~360 nucleotides[1,2], and the mechanism by which these smallest of all known infectious agents replicate in host cells has been extensively studied. Earlier work suggested that viroids replicate using DNA intermediates[3], but rigorous hybridization experiments[4,5] failed to detect DNA complementary to potato spindle tuber viroid (PSTV) in infected plants, and there is no specific inhibition of viroid synthesis[6] by actinomycin D. There is strong evidence that the replication of viroids involves RNA intermediates. *Citrus exocortis* viroid (CEV)[7,8]-infected and PSTV-infected[4,9,10] tissues have been shown to contain RNA that is complementary to the infecting viroid, and recently it was shown that DNA-dependent RNA polymerase II, isolated from tomato, will produce full-length complementary copies of purified viroids *in vitro*[11]. Because much of the RNA complementary to CEV was shown to be double stranded, it could be anticipated that viroid-infected tissue contains unique species of double-stranded RNA (dsRNA). Using serologically specific electron microscopy[12], we have now detected molecules of circular dsRNA in crude extracts of PSTV-infected tomato. These molecules have contour lengths that would be expected for a double-stranded intermediate of PSTV.

Using antiserum to dsRNA, serologically specific electron microscopy was used to demonstrate the involvement of dsRNA in the replication of tobacco mosaic virus[13]. Similar assays of PSTV-infected tomato tissue revealed several linear and relaxed circular molecules of dsRNA, whereas extracts of healthy tomato tissue contained a similar number of linear molecules of dsRNA but approximately 10 times fewer circular molecules.

Tomato (*Lycopersicon esculentum* cv. Rutgers) leaves were powdered with liquid nitrogen and ground with 0.1 M Tris-HCl *p*H 8.0, containing 10 mM Na_2EDTA (Tris) (1 ml per g of tissue). The following steps were done at room temperature. Electron microscope grids with carbon-reinforced Formvar films were floated on antiserum to dsRNA, diluted 1/500 with Tris, for 30 min. After washing with Tris the grids were placed on drops of extract for 2.5 h. The grids were washed with Tris and distilled water, dipped in 95% ethanol for 30 s, rinsed with distilled water and placed on drops of 0.1 mg ml^{-1} cytochrome *c* in Tris for 15 min. The grids were washed with distilled water and placed on drops of 0.01 M phosphate *p*H 7.2 for 15 min, then removed from the phosphate and held for 30 s in a stream of drops of 1% aqueous uranyl acetate from a motor-driven syringe equipped with a 0.2-μm filter. They were rinsed by touching to a drop of distilled water for 1 s and blotted dry, then examined under the electron microscope.

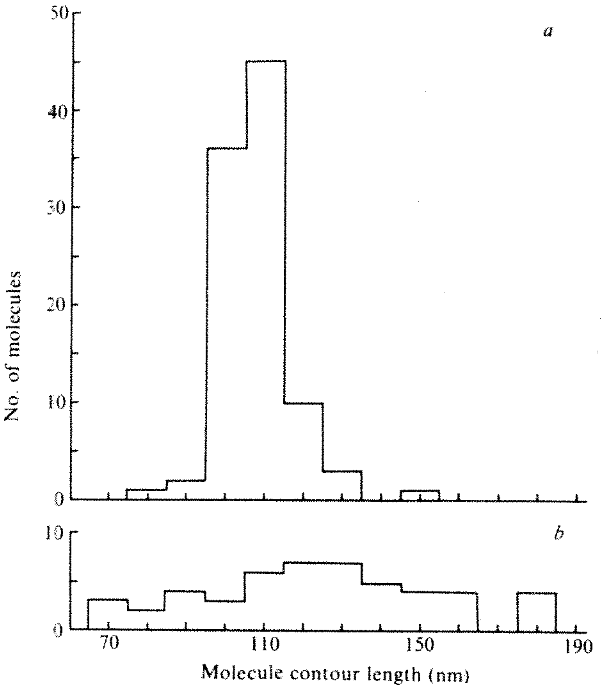

Fig. 1 Histograms of the circumference of circular dsRNA found in extracts of PSTV-infected (*a*) and healthy (*b*) tomato tissue. Electron micrograph negatives of grids prepared as described in the text were projected and the circular forms were traced and measured. We measured a total of 50 molecules from 18 negatives of healthy and 100 molecules from 3 negatives of PSTV-infected tissue extracts.

The assay was specific for dsRNA: neither circular nor linear forms were seen when normal serum or antiserum to a DNA–RNA hybrid were used in the assays. Moreover, the anti-dsRNA serum used (provided by R. M. Lister) does not react

0028-0836/82/030259—02$01.00

with DNA or single-stranded RNA[14]. Assays of PSTV preparations purified by polyacrylamide electrophoresis[15] were negative, confirming an earlier report that PSTV does not react with antiserum to dsRNA[16].

The length of denatured PSTV has been shown to be 100 nm (ref. 17) and 110 nm (ref. 18). Using a linear density of 2.4×10^6 daltons μm^{-1} for dsRNA and a mass of 250,000 daltons, the calculated length of a dsRNA intermediate of PSTV is 104 nm. These lengths compare well with the modal circumference of 110 nm found for the circular dsRNA from PSTV-infected tissue (Fig. 1*a*). The random distribution of sizes of the circular molecules of dsRNA found in healthy tissue suggests they may be closures of linear dsRNA (Fig. 1*b*).

With spherical viruses, the detection limits of serologically specific electron microscopy have been shown to be 10^9 virions per ml (ref. 19). As the number of circular forms attaching to grids decreases rapidly on dilution, the concentration of circular dsRNA in viroid-infected tissue must be of similar magnitude, which is consistent with the low rate of viroid accumulation[15] in the plant.

A + T-rich linkers define functional domains in eukaryotic DNA

J. Moreau, L. Marcaud, F. Maschat, J. Kejzlarova-Lepesant, J-A. Lepesant & K. Scherrer*

Institut de Recherche en Biologie Moleculaire (CNRS), Université Paris VII, Tour, 432 place Jussieu, 75251 Paris Cédex 05, France

Although an increasing number of detailed DNA sequence studies are being carried out, little is known about the long-range organization of the eukaryotic genome in relation to chromosomal organization and to functional units of transcription, replication, meiotic crossing-over and nuclear architecture. Based on electron microscope (EM) observations of partially denatured DNA of duck, mouse and rat, we have recently reported a systematic punctuation of DNA by early melting zones ('A + T-rich linkers')[1] ~800 base pairs (bp) long which are either clustered or at intervals of 10–40 kbp. In an attempt to correlate this feature with the organization of specific genes, we examined cloned genomic DNA from chick and *Drosophila*, including the globin gene family, and an isolated high-molecular-weight mRNA. We show here that the chick α-globin gene cluster is framed by a cluster of A + T-rich linkers at the 5′ end and by an isolated linker at the 3′ end which maps close to the sites of transcription termination and DNase hypersensitivity. The resulting frame of ~15 kbp correlates well with the maximum size of globin gene transcripts found at the pre-mRNA level. The β-globin gene cluster is also framed, 5′ by a single A + T-rich linker and 3′ a cluster of four linkers. In *Drosophila*, the single mRNA sequence of ~3.3 kbp for the ecdysone-inducible P1 protein is similarly delimited by A + T-rich linkers. A + T-rich linkers thus seem to define domains of the eukaryotic genome which may correlate with putative functional units. The specific organization observed in total DNA of duck, mouse, rat, man, chicken and *Drosophila* is confirmed in gene-specific cloned genomic DNA.

Cloned genomic recombinants including the α- and β-globin gene clusters were taken from the chicken 'library' of Dodgson *et al.*[2]. The globin genomic maps shown in Fig. 1 are based on recent publications[3-5] and unpublished data (J. Dodgson, personal communication). Justification of the experimental approach and general methods of partial DNA denaturation and spreading for EM have been reported previously[1]. Briefly, individual recombinant DNA cloned in λ Charon 4A, was denatured at a concentration of 0.5–0.8 $\mu g\, ml^{-1}$ by 85% formamide (24.5 °C), spread by the Kleinschmitt technique, taken up on collodium-coated grids, shadow-casted with palladium/platinum and observed in a Siemens Elmiscope 101 at a primary magnification of ×10,000. The length of the DNA molecules and the positions of melted regions were measured and statistically analysed by a digitizer branched on a HP 9830 calculator. Figure 2 shows two examples of the original micrographs of such partially denatured DNA molecules.

To determine the 5′–3′ orientation with respect to the mRNA sequences and to begin compilation of denatured regions, we used the characteristic denatured regions in the short arm of the λ vector DNA serving also as a very precise 'internal thermometer'. Out of hundreds of molecules observed, a random sample of 20–30 full-length recombinants was measured for any one clone. The data were then realigned with one of the denaturations observed in the chicken DNA inserts so that the position of the melted regions could be plotted precisely. The accuracy of the measurements was of the order of 0.03 nm or ~100 bp. For both α- and β-globin, three recombinants covering all the known chicken globin genes were analysed. In the case of α-globin, the recombinant DNA available comprised the whole gene domain, whereas in the case of β-globin an interruption of 2.1–4.5 kbp (see below) in between $^{\mathrm{H}}\beta$ and $^{\mathrm{A}}\beta$ escaped cloning (J. Dodgson, personal communication).

Figure 1 shows the results of this analysis. The α-gene-type clones, $\lambda C\alpha G2$, $\alpha G5$ and $\alpha G6$, all contain A + T-rich linkers. Starting from the 5′ end (to the left) of the messenger strand, the map starts with a cluster of three denatured regions of lengths 2,040 (possibly originating from two closely placed linkers), 1,050 and 1,350 bp, separated by 520 and 350 bp respectively of undenatured DNA. The next A + T-rich linker of 1,140 bp is found after the 15.0 kbp of DNA spanning all of the α-globin genes; another A + T-rich linker of 650 bp is located after a further 7.5 kbp of DNA, which includes an unknown region. The cluster of A + T-rich linkers occurs 6.5 kbp upstream from the embryonic π gene; this area includes π', a further unmapped α-type gene (J. Dodgson, personal communication). In the 3′ direction, the single linker bordering the α-globin gene domain is 4.0 kbp downstream from the most 3′ $^{\mathrm{A}}\alpha$ gene. Immediately 5′ to the π gene we detected another mildly denaturing sequence of ~890 bp; however, in view of its low frequency of denaturation it seems to be qualitatively different from the 800±200 bp A + T-rich linkers defined previously[1].

The gap in the β-gene domain for which no cloned recombinants were available was determined to be 2.1 kbp in the White Leghorn chicken[3] and 4.5 kbp in the Brown Leghorn chicken (L.M., unpublished); as we found a value of 2.1 kbp for this region in a further stock of chicken, this area seems to be one of genomic variability. Nevertheless, it is unlikely to contain another β-type globin gene.

Partial denaturation of the DNA of three β-globin recombinants gave the following result. Starting at the 5′ end, a single

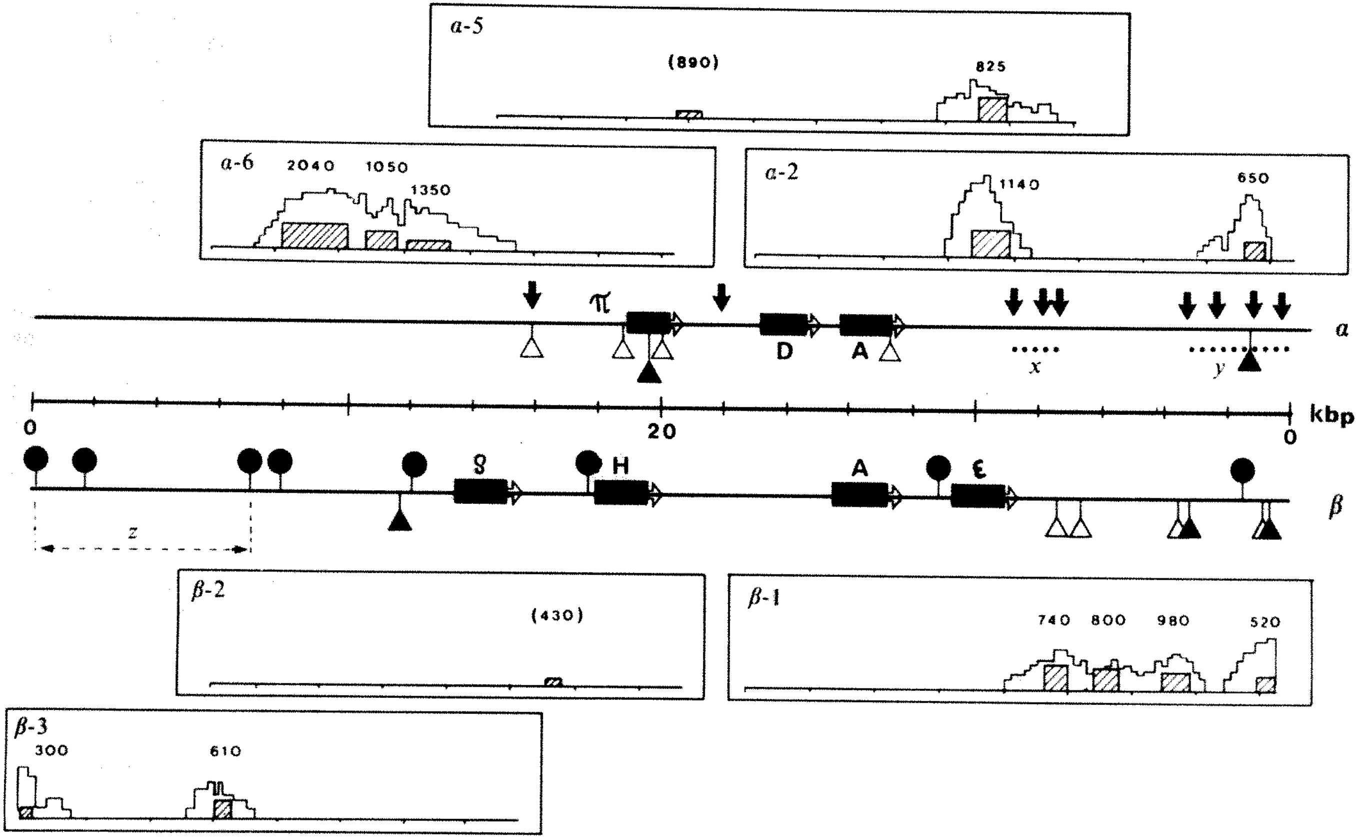

Fig. 1 Globin gene map showing the genomic positions of A + T-rich linkers determined by partial denaturation of cloned recombinant DNA. Insets α-2, α-5, α-6, β-1, β-2 and β-3 show the histograms of frequency of denaturated areas observed plotted against their map position in the cloned DNA, oriented in relation to the long/short arms of the phage DNA. These measurements were realigned against one of the internal denatured zones; means of frequency of occurrence and size of the A + T-rich zones were calculated and represented in the figure by hatched areas and the bp numbers for any one linker. The genomic maps are taken from refs 4 and 5; from the latter came the positions in the globin domain of an area highly resistant to DNase I (*z*) and of hypersensitive areas in the α-globin gene domain (*x*, *y*). Solid arrows mark the positions of methylated *Msp* sites; other restriction enzyme sites used to align the various cloned recombinant DNA: △, *Hin*dIII; ▲, *Eco*RI; ●, *Bam*HI). Recombinants from the chick genomic library were λCαG2, -G5, -G6 and λCβG1, -G2, -G3 (refs 3, 4).

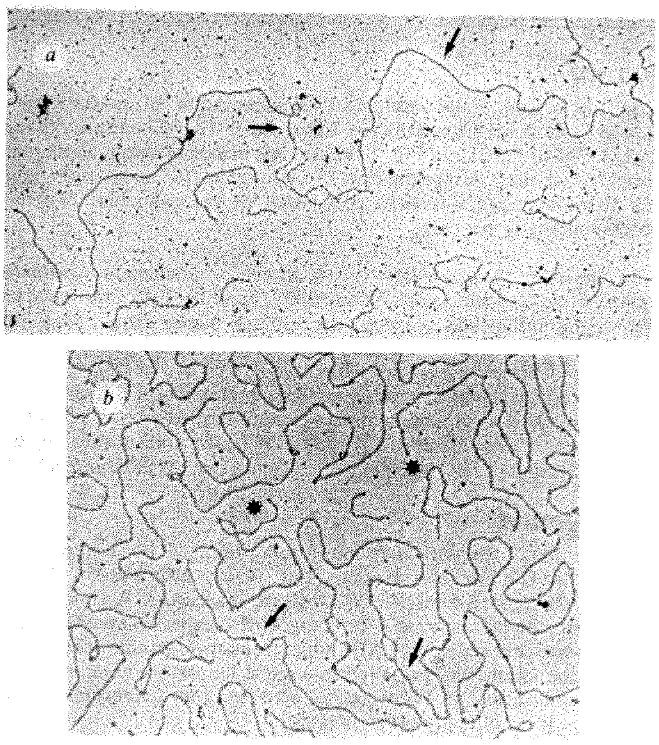

Fig. 2 Partial denaturation of chicken DNA including globin genes cloned in phage λ Charon 4A. DNA was denatured and spread for electron microscopy as described previously[1] and in the text. Arrows indicate the approximate limits of the chicken DNA inserts. *a*, One molecule of clone α-6; the loops include 2,840, 1,290, 1,185 bp; *b*, one molecule of clone (α-2); the loops measure 1,590 and 1,210 bp. The small molecules correspond to pBR322 used as length standard.

610-bp linker was observed, which may be part of a cluster placed further upstream, outside the cloned area. With the possible exception of a very rarely denaturing site 430 bp long, there is no other A+T-rich linker in the 14.0-kbp domain covering the embryonic ρ and $^{H}\beta$ genes, which is limited to 5′ by the interruption. Beyond this gap there is another 9.0-kbp undenatured stretch covering the adult $^{A}\beta$ and embryonic ε-globin genes before a cluster of four consecutive linkers of 740, 800, 980 and 520 bp, separated by 0.94, 1.6 and 2.3 kbp respectively.

In a second approach we analysed a *Drosophila* gene which does not belong to a gene family comparable with that of the globins and which codes for the fairly high-molecular-weight (110,000) ecdysone-inducible P1 protein of the fat body. Its ~3.5-kbp mRNA has been mapped on cloned genomic DNA to the 70 D1-3 region (H. Brock, personal communication) of the 3L polytene chromosome; the gene contains no intervening sequence[6–8].

Partial melting of genomic DNA cloned in phage λ Charon 4, carried out as in the experiments reported above, shows that this area is particularly rich in clusters of A+T-rich linkers (not shown); total embryonic *Drosophila* DNA shows melting patterns generally analogous to those of birds and mammals (ref. 1 and J.M., in preparation). The P1 gene maps in the middle of the phage λ Charon 4 recombinant λDm 117; the central fragment delimited by *Hin*dIII restriction sites was recloned in pBR322 (ref. 8). Figure 3 shows that the P1 mRNA sequence of clone pDmP 1 originates within an A+T-rich linker and runs into a relatively G+C-rich area delimited at a distance of ~5.5 kbp by another A+T-rich linker. The pattern shown in Fig. 3 is typical of several other *Drosophila* genes on the same or other chromosomes—LSP-1β, LSP-1γ and the P6 genes[7]; in each case the mRNA sequence is in a non-denaturing area framed by A+T-rich linkers (J.M. *et al.*, in preparation).

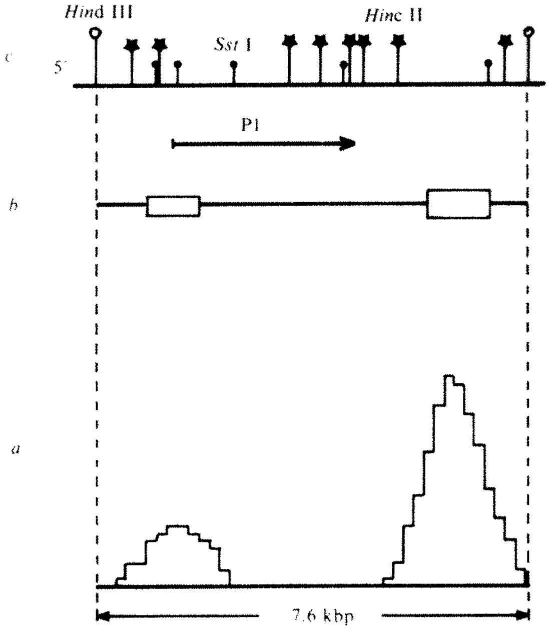

Fig. 3 Partial denaturation of cloned *Drosophila* DNA including the gene for the P1 protein. The DNA of the pBR322 recombinant pDm P1 (ref. 8) was linearized with the *Eco*RI restriction enzyme, denatured as explained in the text in 80% formamide at 24.5 °C, spread for electron microscopy and visualized as explained elsewhere[1]. *a*, Histogram of relative frequency of denaturation of any given segment of DNA, in relation to the ends of the molecule including pBR322 DNA. For higher precision the same measurements were realigned with respect to one of the denaturations in the *Drosophila* DNA and recorded as boxes with a length proportional to the average size of the denatured segment and a width porportional to the frequency of denaturation (*b*). *c*, A partial restriction map taken from refs 7, 8 of the cloned fragment used to position the P1 mRNA sequence.

Three main conclusions may be drawn from this analysis. (1) The fundamental features of A+T-rich linkers as observed in total DNA of chicken, duck, rat, mouse, man and *Drosophila* are found in specific cloned DNA fragments as well. In particular, the average size of the A+T-rich zones, and of the domains separating them, falls within the limits defined previously[1]. Furthermore, the characteristic homogeneous size of isolated linkers on the one hand and clusters of linkers, including A+T-rich linkers of more variable size on the other was also the case in the cloned DNA. (2) The most striking observation may be the clear-cut framing of both the α- and β-globin gene domains by the A+T-rich linkers. (3) The data on *Drosophila* show that A+T-rich linkers may frame individual genes and thus define putative units of gene function. Furthermore, considering recent sequence data of actin[9] and histone[10] genes, it may be the general case that genes or gene domains are placed between A+T-rich zones of the type described here.

Two correlations are of interest. First, the ~15 kbp of the chicken α-globin gene domain, as defined by the A+T-rich linkers, correspond to the maximal size of the transcriptional units found at pre-mRNA level for both the α- and β-globin genes in duck[11]. Recent data[5,12] have confirmed that in mouse and chick, pre-mRNA exists beyond the CAP-poly(A) boundaries. At the 3′ end of the chick $^{A}\alpha$-globin mRNA sequence a further 3 kbp of genomic DNA are co-transcribed[5]; this is about the distance separating, for example, the $^{A}\alpha$ gene from the next A+T-rich linker in the 3′ direction (compare with Fig. 1). Placing the largest (15 kbp) α-globin pre-mRNA reported[11] upstream from this termination point shows that the promoters for these maximal-size transcripts must be in or close to the 5′-framing A+T-rich linker. Second, the mapping of DNase hypersensitive sites, methylation sites and areas of transcriptional activity[5] also reveals correlations with the A+T-rich linker map given in Fig. 1 (see dotted lines and bold arrows). In the α-gene domain, the 3′-hypersensitive sites almost coincide with the corresponding A+T-rich linkers, and most of the methylated *Msp*I sites map within the same A+T-rich linker areas. A region of high DNase resistance correlates with the area immediately to the left of the A+T-rich linker which borders the 5′ end of the β-globin gene domain (dashed line in Fig. 1).

The present data confirm that the A+T-rich linkers are general elements of long-range DNA organization. Furthermore, the clearcut definition of the α- and β-globin gene domains and of the *Drosophila* P1 gene by these linkers suggests that they may have a role as organizational features defining domains of gene function. It is evident that DNA serves multiple functions, not all of which are directly involved in protein synthesis or transcription. The A+T-rich linkers, occurring outside the coding and transcribed areas, might also be involved in DNA functional organization at the chromosome/genome level.

We thank Drs J. Dodgson and D. Engel for their library of cloned chicken DNA and the globin gene-containing clones, Helene Grimal for technical assistance, and members of our team and of the staff of the EM laboratory at the IRBM (director Dr L. Benedetti). We particularly thank Mrs Chantal Cuisinier and R. Schwartzmann for help in preparation of this manuscript. This work was supported by the French CNRS, Délégation Générale à la Recherche Scientifique et Technique, Fondation pour la Recherche Médicale Française and Institut National de la Santé et de la Recherche Médicale.

Errata

In the article 'Palaeontological documentation of speciation in Cenozoic molluscs from Turkana Basin' by P. G. Williamson, *Nature* **293,** 437–443 (1981), in Fig. 3 the top left principal components plot should be labelled '*A*', the top right '*B*', bottom left '*C*' and bottom right '*D*'. In the legend references to parts *a–d* of the figure should refer to the corresponding upper case.

In the letter 'Autoregulation of androgen production in a primary culture of rat testicular cells', *Nature* **293,** 737–738 (1981), the name of the second author was misspelt; the authors' names should read 'Eli Y. Adashi & Aaron J. W. Hsueh'.

In the article 'Glucocorticoids regulate expression of dihydrofolate reductase cDNA in mouse mammary tumour virus chimaeric plasmids' by F. Lee *et al., Nature* **294,** 228–232 (1981), the first sub-heading on page 232 should read 'Mapping the 5′ end(s) of MMTV-*dhfr* RNA'.

Corrigenda

In the letter 'Immune (γ) interferon produced by a human T-lymphoblast cell line' by I. Nathan *et al., Nature* **292,** 842–84 (1981), some of the reported interferon titres are inaccurate. A commercial interferon standard was used in many of the experiments. This preparation was checked against NIH human leukocyte standard; however, some of the commercial preparations used as laboratory standards were subsequently found to be defective, leading to an overestimation of interferon titres of approximately tenfold.

In the letter 'Expression of a human gene for interferon in yeast' by R. A. Hitzman *et al., Nature* **293,** 717–722 (1981), refs 10 and 18 should read:

Guidance system for pheromone orientation in moths

THE explanation proposed by Kennedy and co-workers[1] of a new guidance system for pheromone orientation contains several conclusions inconsistent with previous publications: (1) the conclusion that "persistent upwind flight requires decreases as well as increases in the pheromone stimulus" conflicts with the behaviour reported for another moth *Anagasta kühniella*[2], and the persistent upwind orientation of flying *Drosophila*[3], walking silk moths[4], cockroaches[5] and grasshoppers[6] to uniform and constant odours. Possibly the sustained upwind flight could not be elicited in *Adoxophyes orana* because the concentration in the cloud was too low: "at least 30 times lower than the average concentration in the plume".

(2) The hypothesis that zig-zagging and casting flight is a programmed function of pheromone concentration and that "the amplitude of these cross-wind movements change(s) inversely with the strength of the pheromone stimulus" cannot be supported critically by only the anecdotal comparison of *A. orana* flight without pheromone against that in a single pheromone concentration. Alternatively these observations might only be associated with the presence or absence of pheromone.

(3) That "zig-zagging and casting flight is not a response to loss of pheromone" is not adequately supported by noting "frequent track reversals inside the pheromone corridor". An alternative conclusion is that not all turns are elicited by the same mechanism. Reversal turns not related to a plume boundary have previously been reported in other insects[4,5], but this does not imply that turns made specifically at the boundary or after a change in the pheromone concentration are not elicited as a stimulus response. For example, cockroaches turn both at the plume boundary and at irregular points within the plume[7].

An integrated orientation system rather than the models discussed by Kennedy and co-workers[1] would be more consistent with present information. In an integrated system, several factors contribute to the control of the rate and patterns of turning, including compensatory turns made to correct deviations from the preferred wind angle, reversal turns made at the plume boundaries, stochastic turns, and turns initiated internally at a regulated frequency if a turn has not yet been elicited by one of the previous factors. In addition, the concentration of pheromone must also regulate the flight speed and the preferred wind angle.

KENNEDY *ET AL.* REPLY—The new guidance system we proposed is admittedly inconsistent with earlier publications, not least our own, and was therefore not lightly arrived at. Tobin and Bell's numbered points are discussed briefly below but reference should also be made to the full account of this work which appears elsewhere[1].

(1) In the long run some inconsistencies will surely turn out to reflect real differences between cases. However, for the moment note that the only two published examples[2,3] of persistent upwind flying—as distinct from walking—in uniform odour are anecdotal. Our reason for mentioning the non-persistent upwind flights in the very low concentration of our tunnel-filling pheromone cloud, was existing evidence from other moths[4,5] that upwind flight is retarded by high rather than low pheromone plume concentrations. However, we also mentioned non-persistence in our side 'corridor' pheromone cloud, and the concentration in that was higher than the average in the broken pheromone plume where upwind flight was persistent[1]. Thus we concluded that the non-persistence recorded was due to the continuity of stimulation in the unbroken pheromone clouds, not the concentration.

(2) The quoted remark did refer only to the presence or absence of pheromone, but it rested on the non-anecdotal[1] finding that onset of the pheromone stimulus reduced the amplitude of cross-wind movements while cessation of the stimulus increased it; and, in another flying moth, changing the concentration of pheromone present has likewise been shown to produce an opposite change in amplitude[4].

(3) We expected, but did not find, some evidence of pheromone loss inducing cross-wind reversal of the flight track by *Adoxophyes orana*. Of course, we cannot say it never happens, but we can say that the probability of such a reversal increases significantly on entering pheromone[1]; and in another moth cross-wind movements had already been shown to lengthen on leaving pheromone[5].

Like Tobin and Bell, we regard this guidance system as a highly integrated one[5,6] but go further in regarding the stochastic reversal turns, not as a separate class of turn, but as turns initiated internally at a frequency that is regulated stochastically by the pheromone inputs.

Tilt of the central gas disk of the Galaxy

BLITZ *ET AL.*[1] have suggested that the tilt of the central galactic gas disk might be explained by a bending wave instability due to a gravitational interaction between the thin gas disk and the central stellar bulge. However, the instability theory due to Bertin and Mark[2] on which this suggestion is based, is inapplicable in the case of the central gas disk. For the theory to apply, the vertical gravitational forces on the gas disk must be due largely to its own self gravity with only a small contribution from the bulge. The frequency of the bending waves of a thin self-gravitating disk is then given by[2,3] $(2\pi G\Sigma k)^{1/2}$ where Σ is the surface mass density and k is the radial wavenumber of the bending wave, yielding the group velocity used by Blitz *et al.*[1] to predict the scaling law for the height of the bend (h) as a function of radial distance from the galactic centre (r).

However, the gravitational force experienced by the gas disk between $r =$ 300 pc and 2 kpc is dominated by the stellar potential. The central stellar bulge is in fact significantly flattened[4] (major and minor semi-axes are 2.5 and 1.3 kpc), while the stellar disk component (thickness ~500 kpc) is not completely negligible in the central region[4]. The magnitude of the vertical gravitational acceleration at height h due to the stellar potential is therefore approximately that of an oblate spheroid with mass density ρ_* and eccentricity close to unity[5], that is, $4\pi G\rho_* h$. Whilst the magnitude of the vertical acceleration due to the self gravity of the bent disk can be estimated[2] to be $2\pi Gk\Sigma h$. Using $\rho_* = 6M_\odot \text{pc}^{-3}$ (ref. 6) and $\Sigma = 6M_\odot \text{pc}^{-2}$ (ref. 7) at $r = 1$ kcp, the ratio of the stellar field acceleration to that of the gas self gravity is λ/π, where λ is the wavelength of the bending wave in parsecs. Because $\lambda \sim r$ for the tilt, the

0028-0836/82/030263/01$01.00

stellar force dominates by a factor $\sim 10^2$–10^3, and hence the self gravity of the disk is negligible. Therefore it is invalid to use the Bertin and Mark theory.

A more appropriate approximation would be to consider the bending modes of a gas disk due to motion in the stellar potential alone. The modes obtained from such an analysis[8] which are most closely analogous to the bending wave of Bertin and Mark have a frequency of $\sim(4\pi G\rho_*)^{1/2}$ yielding a very small group velocity in comparison with the phase velocity.

BLITZ AND MARK REPLY—Nelson's suggestion that the Bertin and Mark[1] bending wave theory is inapplicable to the dynamics of the gaseous disk at the galactic centre seems to be based on an incomplete analysis of the singular perturbation problem involved when a disk of small (but not altogether negligible) mass is immersed in a larger spheroidal component.

For disk mass much smaller than spheroidal masses, it is not appropriate to omit the disk mass terms. The 'kinematic waves' resulting from this omission (see equation (D7) of (ref. 1) dominated by v_z^2 on the right-hand side) dissipates on the rather short differential rotation shearing time scale $|d\Omega/d\ln r|^{-1}$. On the other hand, including the dynamical effects of the small disk mass results in self-gravitating waves with the much longer group propagation dissipation time, $\sim 2Rdk/d\omega$, which has the dispersion relation (D7) of (ref. 1). The neglect of similar terms in Nelson's[2] formalism for modes symmetric about the galactic plane would fail to produce the familiar Jeans instability (the bending waves are the antisymmetric disturbances about the galactic plane). By contrast, Bertin and Mark have included terms of the 'sound wave' type included by Nelson, but within the context of galaxy warps, stellar dispersive speeds squared are much larger than the corresponding terms in the gas.

In any case, Bertin and Mark have included terms which reflect more completely the dynamics of the disk. The conclusion with or without these additional terms is that the scaling law ($r\Sigma^2h \sim$ constant) used by us is consistent with the observations of the inner disk of the Galaxy as well as the warps of the outer region of several galaxies as shown by Lake and Mark[3].

Lipoprotein assembly in *Xenopus* yolk-platelet crystals

FROM his determination of the space group of yolk-platelet crystals from several new species, Lange[1] has questioned earlier data of ours for similar lipoprotein crystals from *Xenopus*[2]. The new data are based entirely on electron micrographs from fixed sectioned specimens, a procedure we intentionally avoided during our studies. This evidence as well as a few other statements made in the paper need to be scrutinized.

The first data shown (Fig. 1 of ref. 1) are three 'tracings' of electron diffraction patterns from yolk crystals of the species *Triturus*. It is unfortunate that Lange did not publish the patterns themselves because frequently the high noise level from such poorly diffracting specimens makes interpretation of the patterns difficult. Furthermore, a more analytical description including the averages and standard deviations of the observed lattice spacings would have been useful. It is, after all, the unit cell spacings which we and now Lange, have used to identify specific projections[1,3].

In further criticism of the data presentation, the space group determination using Figs 2 and 3 of ref. 1 is confusing because no optical diffraction patterns are shown and the micrographs were obtained from two different species. Lange's Fig. 3, for example, bears a strong resemblance to the *hol* zone from lipoprotein crystals of *Xenopus*[3]. Lange describes this as the *hko* zone, suggesting that simple relabelling of the *b* and *c* axes would make the results consistent with the earlier work[3]. Indeed, we agree that the projection shown in Fig. 3 should have *pgg* symmetry. As the *b* and *c* axes in the unit cell for *Xenopus* are roughly the same length, they may equally well be similar in other species and could easily be interchanged. Unit cell dimensions can be precisely obtained for wet and dry crystals by using X-ray powder methods[3].

In image reconstruction studies, the best way to determine the symmetry of a given projection is to examine the phases of strong symmetry-related reflections[4]. In the studies of the lipoprotein complex from *Xenopus*, phases of each centric projection were calculated and were then shifted to minimize the difference between that calculated and the nearest real value[2,5]. Two pairs of strong reflections on the 001 projection ($1, 3, 0$ and $1, \bar{3}, 0$; $2, 3, 0$ and $2, \bar{3}, 0$) had phase relationships consistent with only *pmg* symmetry[5]. Six pairs of reflections had phase relationships consistent with *pgg* symmetry for the view we assigned to the *hol* projection. Many of the projections used in the image reconstruction were studied earlier by optical filtering methods. Even on such filtered images, both the number of molecules and the symmetry can be difficult to ascertain[6].

Furthermore we take issue with Lange's discussion of the reliability of positive versus negative staining[1] in special reference to our image reconstruction results. Certainly the appearance of lattice micrographs will be different when one is positively stained and the other negatively stained. However, the immobilization of stain (positive staining effects) adjacent to solvent channels filled with stain (negative staining), is unlikely to produce major artefactual results. Thus, we emphasize the importance of negative stain as well as the lack of chemical fixation in the earlier study[2].

Finally, we note that although the work on *Xenopus* was severely limited by the chance finding of different crystal fragments, it still contained data from 10 different views selected from several hundred electron micrographs[2,3].

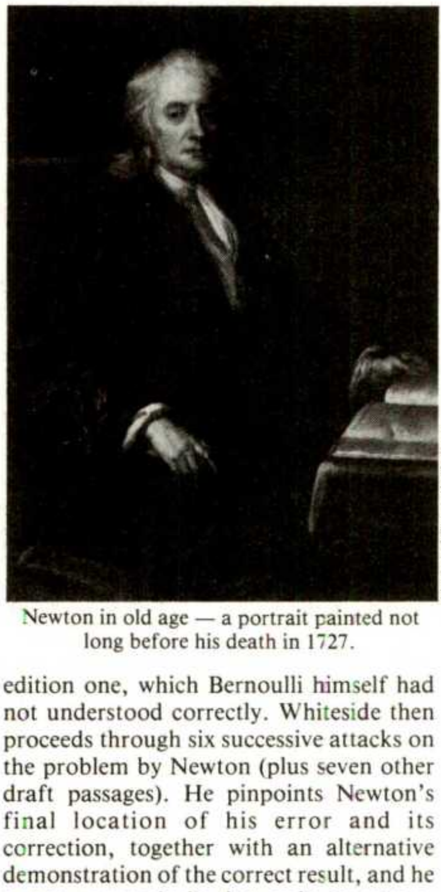
BOOK REVIEWS

Newton's achievements: from rumour to fact

Richard S. Westfall

The Mathematical Papers of Isaac Newton Vol.VIII, 1697–1722. Edited by D.T. Whiteside. Pp.704. ISBN 0-521-20103-9. (Cambridge University Press: 1981.) £85, $195.



Newton in old age — a portrait painted not long before his death in 1727.

National Portrait Gallery

VOLUME VIII, which, except for a promised volume of indexes, concludes D.T. Whiteside's monumental edition of *The Mathematical Papers of Isaac Newton*, is more of biographical than of mathematical interest. It takes up the final desultory efforts of a man who had recently celebrated his fifty-fourth birthday when the volume commences and had also chosen to fill his life with the administrative minutiae of the Royal Mint instead of the labours of a Lucasian Professor of Mathematics. The volume contains very little original mathematics; almost all of the mathematical activity it displays was provoked by the immediate demands of the battle with Leibniz over priority in the invention of the calculus. Fittingly, it concludes with a draft of an intended preface for the 1722 edition of *Commercium epistolicum*, the volume of letters and papers that Newton himself had secretly compiled and edited and that the Royal Society had published in 1712 as the report of an "impartial" committee appointed to investigate Leibniz's complaint. When he wrote that preface, Newton was approaching 80 years of age. As he himself once said, no old men (excepting Dr Wallis) love mathematics, and it is not surprising that Whiteside finds nothing to include from his remaining five years of life.

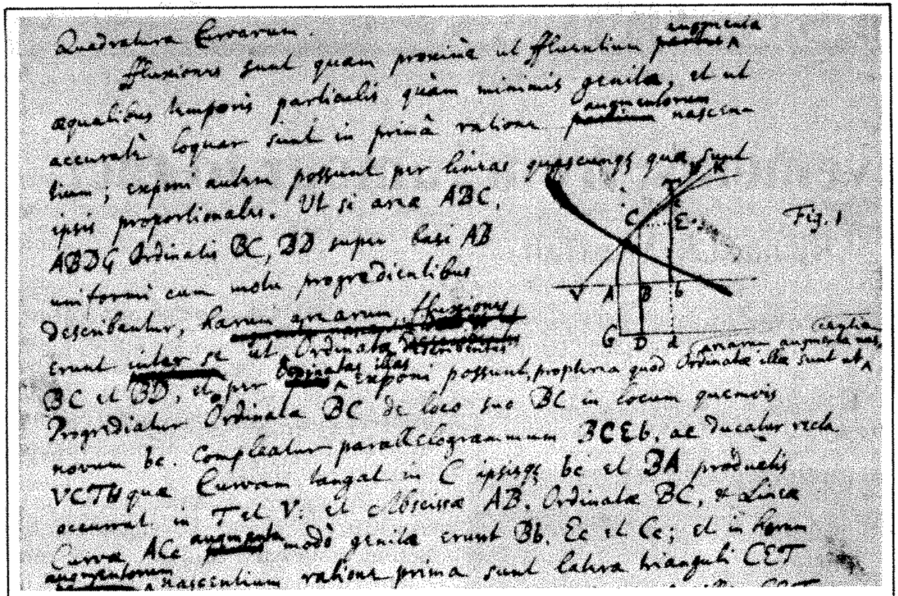
Do not mistake the paragraph above as criticism of Vol.VIII. A complete edition of Newton's mathematical papers could not neglect these manuscripts, and to say that they are more of biographical than of mathematical interest is in no way to suggest that they have no interest at all. It is part of the editor's achievement that he infuses into their publication learning equal to that which he devoted to Newton's earlier creative endeavours in mathematics. Thus he conducts us through Newton's responses to the two challenge problems posed by Bernoulli, the initial publication during the first decade of the eighteenth century of various papers written earlier, relevant aspects of the second edition of the *Principia*, and the venomous exchange with Leibniz and his followers on the issue of priority which spread out over a full decade. Whiteside's presentation of the correction of Proposition X, Book II, for the *Principia*'s second edition is a *tour de force* in the full sense of the phrase. From Newton's papers he has assembled the sheets on which Newton confirmed the validity of Bernoulli's objection, and he shows in detail the exact nature of the error in edition one, which Bernoulli himself had not understood correctly. Whiteside then proceeds through six successive attacks on the problem by Newton (plus seven other draft passages). He pinpoints Newton's final location of his error and its correction, together with an alternative demonstration of the correct result, and he argues persuasively that only an unperceived computational error prevented Newton from realizing that he could have amended the proposition within the framework of the original demonstration without the complete redrafting that he finally inserted (to his embarrassment) in edition two.

Whiteside concludes the volume and the edition with 160 pages of documents from Newton's own extended effort to defend his right as true inventor of the calculus. Not long ago, in Vols VI and VII of Newton's *Correspondence*, an extensive documentary history of the priority dispute was published. Naturally the focus was on correspondence, including many hitherto unpublished letters from the Continent. The drafts of Newton's defence of his priority that Whiteside publishes thus supplement, rather than repeat, the *Correspondence*. His lengthy introduction, the valuable account of the priority dispute by the man who knows more about the subject than anyone ever has or is likely to again, likewise complements the masterful *Philosophers at War* by A.R. Hall, the editor of those volumes of the *Correspondence*.

It is fitting now, with the completion of Vol.VIII, to assess the entire edition. Before Whiteside began, we knew comparatively little about Newton's work in mathematics. As Whiteside states in the preface to the present volume, Newton failed to impress the fact, as distinct from the hearsay, of his mathematical achievement on his contemporaries. The period of more than two centuries that followed Newton's death did not amend that state of affairs. Furthermore, Newton did not arrange his papers to facilitate an editor's work. Only Newton scholars who have worked on the manuscripts themselves can appreciate the initial stage of Whiteside's labour, finding his way through what he aptly describes as "the disordered limbo of Newton's private papers".

Volume VIII offers two striking displays of the extent to which he has mastered these difficult manuscripts, though one could find similar examples in every volume. He has identified an unlabelled page of miscellaneous calculations as Newton's demonstration of the essence of Fatio de Duillier's novel solution of Bernoulli's problem on the line of quickest descent (pp.86–91). And from sheets dispersed in both the Portsmouth Papers in the Cambridge University Library and the Macclesfield Papers in Shirburn Castle he has reassembled much of the manuscript for a treatise on fluxional analysis that Newton composed to append to the *Principia*'s second edition. The papers were separated soon after he dropped the idea; thus Whiteside has resurrected an essay which has not existed as a single entity since its composition nearly 270 years ago (pp.258–296).

Impressive as his achievement in arranging the manuscripts is, it pales in comparison to the real work of infusing them with understanding so that the invention of the calculus and a great deal more once again spring to life. In effect Whiteside has done for Newton what Newton failed to do for himself; he has transposed his mathematical achievement from the realm of rumour to the realm of fact. Because of the inherent difficulty of the material, there is no way in which such a work can be made easy for the reader, and



In his own hand — part of the marked-up first page of the printer's copy for the 1704 *De Quadratura Curvarum.*

because Whiteside has brought a high level of mathematical expertise to his task, the edition is doubly difficult. I myself have criticized earlier volumes on this score, arguing that the technical level of the edition effectively closes it to all but a tiny handful of readers. I have come to the conclusion that this criticism was ill-considered, and I take this occasion to apologize to Whiteside. Nonetheless, I still hold the idea that animated it: that it will be a tragedy if the knowledge the edition makes available of Newton's achievement in mathematics, one of the supreme triumphs of the human spirit, does not reach beyond the confined circle of professional historians of mathematics. As it now appears to me, Whiteside has done quite right in treating the papers with a level of sophistication that matches their own. It belongs to others, including Newton scholars such as myself, to translate the achievement into a broader idiom without vulgarizing it. If we fail in the task, we, rather than Whiteside, should be the object of criticism. With this magnificent edition, we cannot complain of an inadequate source.

In a work of such magnitude, there are bound to be — I will not say errors — but a few things that seem to me to be misjudgements. In Vol. VII, annoyed by Newton's apparent revulsion from modern analysis in the 1690s and by his preference for classical geometry, Whiteside has put together a work on *Geometria* in two books, which seems to show that Newton reversed himself once more to embrace analysis anew at the end of his active career in mathematics. By comparing the original manuscripts, I have convinced myself that in this case Whiteside has created an artificial work that never existed, joining a manuscript from the 1680s to a totally separate one from the 1690s in order to portray Newton as he would prefer him to have been. It seems to me, further, that he made a serious mistake in not including the two *epistolae* written in 1676 for Leibniz, even if their texts (though not Whiteside's commentary) are readily available in the *Correspondence*. In an edition notable for its completeness, their absence is the only major omission. Third, I think he erred in substituting the form $\dot{x}$, $\dot{y}$ and $\dot{z}$ for Newton's *m*, *n* and *r* in his translation of *De methodis* of 1671. "Pricked letters", as Newton called the distinctive notation he later devised, assumed some significance in the priority dispute. Readers tend always to use an available translation, and they are apt to be misled by it in the present case. I could list a few more possible defects; but if I have reached this level of triviality with my third, it should be obvious how few and how small I take them to be.

A few years ago I hailed Whiteside's work as the finest edition of scientific papers ever published. I now think that judgement was inaccurate. It erred in being too restrained. I am convinced that *The Mathematical Papers of Isaac Newton* is one of the outstanding scholarly achievements of the twentieth century. Where other editorial projects concerned with less difficult materials have created veritable factories, Whiteside has equipped himself primarily with a writing pad, a pencil and, to restrict himself more fully to his study, a stack of xeroxes. Upon the latter he has exercised an extraordinary level of technical expertise joined to an extraordinary level of devotion. How seldom do the two qualities, raised to such a degree, come together. With them, Whiteside has built what every true scholar dreams of constructing, a monument which will endure through the centuries as part of mankind's precious legacy of learning. ☐

Iron in the soul

Walter Gratzer

The Nobel Duel. By Nicholas Wade. Pp.321. ISBN 0-385-14981-6. (Anchor Press/Doubleday, New York: 1981.) $15.95.

ONE of the elders of modern biochemistry once recounted how, in the days before peer-review was invented, his benefactor would from time to time visit the laboratory to see what use was being made of his largesse. He inquired on one such occasion whether he could be of any further help and, being told that ten dollars for the purchase of frogs would be welcome, he drew out his wallet, laid two five-dollar notes on the laboratory bench and took his leave.

Well, the past, it has been said, is another country, where they order their affairs differently. The pursuit of the pituitary releasing factors, which is the subject of Nicholas Wade's book, consumed many millions of dollars, the undivided efforts of postdoctoral research fellows, students and technicians in something approaching battalion strength and, according to one estimate, the brains of five million sheep in the isolation of thyrotropin releasing factor alone. The investment was all but wasted: in 1969 the Study Section of the NIH that had supported the two duellists of this story, Guillemin and Schally, through many years of seemingly unproductive toil, came close to deciding that enough was enough. In the words of a member of the committee, the programme was "within an eyelash of being abandoned". The releasing factors had been compared by a respected endocrinologist to the Loch Ness Monster, and Guillemin and Schally had brought ridicule on themselves by an obsessive antagonism that regularly expressed itself in public brawls at conferences.

Sustained by the manic intensity that distinguishes the barons of science from the cannon-fodder in their campaigns, both survived. Each, on the testimony of this account, has an ego like a raging ulcer, as much sensitivity or remorse as a runaway locomotive and awesome reserves of single-mindedness, tenacity and courage. They have in superabundance what Noel Coward defined as the secret of success — the capacity to survive failure. But, in the words of a discarded collaborator of Schally's, such men "are not lovable types". Whether on balance they serve science well, the reader will have to decide for himself.

Nicholas Wade has an engrossing tale to tell and does it in masterly fashion. He does not allow the interplay of personalities that provides much of the drama to obscure the science, which he handles with enviable assurance. No less remarkable is the way in which he has made his cast of characters speak for themselves and has drawn from their mouths reflections of marvellous candour

In the beginning was Geoffrey Harris, the English physiologist, who first postulated that the brain directs the release of pituitary hormones by despatching chemical messages from the hypothalamus to the pituitary Guillemin and the Canadian endocrinologist, Murray Saffran, with whom Schally was then working as a technician, obtained early and independent evidence of the existence of such factors, and there ensued an uneasy collaboration between Schally and Guillemin that soon gave place to an ungovernable rivalry According to *The Devil's Dictionary* calamities are of two kinds, misfortune to ourselves and good fortune to others. Guillemin and Schally dogged each others' footsteps through success and failure, each cast down by the other's victories and elated at his defeats, when, for example, Schally's group took for a releasing factor a proteolytic fragment of myoglobin, which they laboriously isolated and sequenced after processing a quarter of a million brains, Guillemin did not conceal his pleasure

In the laboratory it seems that both Guillemin and Schally (though both had proved their ability as young men) made only minor contributions to the work of their groups, but it was they who kept their groups in being The burden of the science was borne by a superlatively capable corps of young men — Burgus and Vale, Ward and Brazeau for Guillemin, the Japanese, Arimura, Matsuo and Baba, together with Radding, Carter and Nair for Schally Their efforts were ill-rewarded — indeed, on the evidence here, it is small wonder that a postdoctoral liberation movement of a kind appears to be emerging in the United States

Both teams had remarkable achievements One that stands out is a dazzling feat of peptide chemistry by the Japanese visitor, Matsuo, who determined the sequence of LRF by simultaneous analysis of unfractionated, overlapping proteolytic fragments on 50µg of material, and so won the race for Schally

The Nobel Duel is a hugely entertaining read, but it is also much more, for it lays bare the mechanics of Big Science (into which biology is being increasingly assimilated), and exposes its virtues and blemishes to public view Whether the process of discovery feeds on such ferocious competitiveness as is here on display is an interesting and indeed important question Wade opines that other highly regarded workers in the field, such as Saffran and Hearn, had too much of a sense of humour and of the fitness of things to engage in such destructive proceedings, this fastidiousness, just as a classical education has been alleged to do, enabled them perhaps to despise the success that it prevented them from achieving Nonetheless, it is remarkable how close other laboratories with vastly smaller commitments and funds, such as that of Harris, came to a solution of the problem

A piquant footnote to the history of the long haul to the structure and function of the releasing factors is the reaction of an early adversary of Harris's, that most entrenched of all the illuminati of the scientific establishment, Lord (Solly) Zuckerman He, it seems, remains adamant that Harris was wrong from the outset and that the pituitary hormone releasing factors are, after all, no more than a mirage □

The second volume of Colin Ronan's *The Shorter Science & Civilisation in China* has just been published by Cambridge University Press The book is an abridgement of the material in Vols III and IV/I (for reviews see *Nature* **186**, 36 and **196**, 844) of Joseph Needham's original text, and costs £15

Mysteries of the zeta potential examined

John Gregory

Zeta Potential in Colloid Science. Theory and Application By Robert J Hunter Pp 386 ISBN 0-12-361960-2 (Academic Press 1981) £35, $84

ELECTROKINETIC phenomena, such as streaming potential and electrophoresis, have been known for over a century They arise whenever there is relative motion between a charged interface and a liquid and are usually interpreted in terms of the zeta potential, which is conventionally defined as the electric potential at the plane of shear There has always been an air of mystery surrounding the concept of zeta potential, partly because of theoretical problems concerning the structure of the electrical double layer and the precise location of the shear plane within it, and partly because of difficulties in obtaining reliable experimental values Although there have been several books on electrokinetic phenomena generally, Professor Hunter's is the only one, to my knowledge, which is devoted to the enigmatic zeta potential itself

To a large extent, the book is successful in drawing together and rationalizing a vast amount of material covering many aspects of the subject It should be essential reading for those embarking on research in the area and most established practitioners will want to have a copy within reach, or at least in the library of their institution

After a brief, scene-setting introduction, the author first deals with the distribution of charge and potential at interfaces Most of this material is readily available elsewhere and the treatment here offers no new insights However, since it forms the basis of much of what follows, it could not reasonably have been left out

By far the most useful chapters are those concerned with experimental techniques and the calculation of zeta potentials There is an exceptionally clear and up-to-date exposition of the procedures for obtaining zeta potentials from electrophoretic mobilities The experimental chapter includes a wealth of practical detail, such as the design of electrophoresis cells, and even advice on how to avoid leakage problems with platinum streaming potential electrodes

The chapter on electroviscous and viscoelectric effects is an admirable survey, a task which does not seem to have been previously attempted Hunter's conclusion from the discussion of viscoelectric effects is that the electrokinetic plane of shear cannot lie too far from the outer Helmholtz plane and that the zeta potential must be nearly equal to the potential just inside the diffuse layer This will comfort the many colloid scientists who have been making similar assumptions for years, but those who have advocated comparatively thick layers of structured water at interfaces may still remain unconvinced

The remainder of the book is concerned with applications of zeta potential and the effect of simple inorganic ions and more complex adsorbates The discussion of oxide surfaces raises the important question of the distinction between points of zero charge and isoelectric points, but, unfortunately, in an uncharacteristic lapse from his usually clear style, the author creates some confusion, especially with regard to the role of specifically adsorbed ions There are mentions of applications in such areas as colloid stability, flotation and electrophoretic deposition, but they are too brief to do justice to these various subjects

It becomes evident from the final chapters that there are still major uncertainties concerning the nature of the electrical double layer at solid–liquid interfaces In some cases, experimental values of charge density and zeta potential can only be reconciled with current models by making rather unrealistic assumptions, as the author readily admits Perhaps it is time for a thorough reappraisal of concepts such as the Stern layer and molecular capacitors, bearing in mind that on this scale (c 1 nm) water is not a structureless medium and that real surfaces are almost never smooth □

John Gregory is Reader in Water Chemistry in the Department of Civil Engineering, University College, University of London, and Secretary of the Colloid and Surface Chemistry Group, Society of Chemical Industry

Single-system geology after Arkell

Janet V. Watson

Lower Palaeozoic of the Middle East, Eastern and Southern Africa, and Antarctica With Essays on Lower Palaeozoic Trace Fossils of Africa and Lower Palaeozoic Palaeoclimatology
Edited by C H Holland Pp 331 ISBN 0-471-27945-5 (Wiley 1981) £38, $84

"It has been my personal experience that anyone seeking to understand a single geological system must flounder in the literature for some twenty years   Users of this book will be saved some twenty years work" This wry statement comes from the preface to W J Arkell's *Jurassic Rocks of the World* (Oliver & Boyd, 1956), the first general synthesis of a single system on a world-wide basis During the quarter-century since its publication the need for regional or global syntheses has increased, and the volume under review is therefore sure of a welcome It is the third of an ambitious series focused principally on the Cambrian, but taking in Ordovician and Silurian rocks where the nature of the evidence makes precise chronostratigraphy difficult The regions covered in this volume — the Middle East, north-eastern and southern Africa and Antarctica — are as difficult as any and the decision to cover all of the Lower Palaeozoic systems seems wise

In introducing his now classic volume on the Jurassic, Arkell outlined two objectives

> to present a unified description as a reference work and   to enquire what can be deduced as to faunal realms, climate, palaeogeography, volcanic and plutonic activity and earth movements   during one reasonably circumscribed period of geological activity

Accepting these as the true objectives of any comparable work, one must say immediately that the principal authors here (R Wolfart, E Klitzsch, I C Rust and M G Laird) have dealt nobly with the reference aspect They have brought together details of successions in some of the least-visited and least hospitable terrains on Earth and have provided valuable correlation tables and palaeogeographic maps Their chapters will remain the standard references for the Middle East, Libya and adjacent territories, southern Africa and the Ross geosyncline for years to come As a bonus, there are interesting chapters on Lower Palaeozoic trace-fossils in Africa (T P Crimes) and palaeoclimatology (N Spjeldnaes)

But what about Arkell's second objective? The unity of outlook and stylistic grace which he brought to the Jurassic are perhaps unlikely to be achieved in a volume with many authors one could, however, justly look for a broad treatment of geological events in Lower Palaeozoic times A four-page introduction by R M Shackleton reminds us that the areas dealt with are linked by and partially coincide with one of the world's major systems of mobile belts — the Pan-African — which was active immediately before and sometimes during the Cambrian period Scarcely a mention of this relationship is to be found in the rest of the book, with the honourable exception of the Antarctic chapter An opportunity seems to have been lost here, though the long-suffering editor (C H Holland) whose frustrations are outlined in the preface, may well protest that to have asked for a broader treatment would have made his labours impossible

Nonetheless, a fuller introduction or a final review chapter might have made all the difference Stratigraphy is the senior branch of historical geology, but can it any longer afford to close the door on tectonics, metamorphism and magmatism? □

Janet V Watson is a Professor in the Department of Geology at Imperial College, University of London

Landmark of early man in Britain

Paul Mellars

The Lower and Middle Palaeolithic Periods in Britain By Derek A Roe Pp 340 ISBN 0-7100-0600-4 (Routledge & Kegan Paul 1981) £35, $95

No one is better qualified to write a book on the earliest stages of human occupation in Britain than Derek Roe For the past 20 years he has been involved in detailed first-hand work on the sites of this period, and has produced not only the authoritative gazetteer of the major Palaeolithic localities in Britain, but also the most exhaustive typological analysis of the archaeological assemblages themselves The appearance of this general survey of the earlier Palaeolithic material must therefore be regarded as a major landmark in studies of the period in Britain

Two features of the book are particularly impressive its evident authority in dealing with the difficult interpretative issues involved and its readability Dr Roe writes with a degree of clarity, style and fluency which is all too rare in archaeological literature Some might say that the book is over-written in places, but this kind of judgement must depend to a large extent on the kind of readership which is anticipated Dr Roe has clearly aimed at an audience which includes not only the specialist prehistorian but also the "interested layman", and for this mixed readership his style of presentation is probably ideal

To pick out particular features of interest in a book of this scope is an almost impossible task Perhaps the most significant single feature which emerges from the discussion is the rapidly increasing evidence for the occupation of southern Britain by hand-axe-using communities at some point substantially prior to the Hoxnian interglacial Roe's arguments for believing that sites such as Fordwich (Kent) and Kent's Cavern (Devon) belong to this early phase are to my mind almost conclusive, and for these sites an age of at least 350–400,000 years would, from several lines of evidence, seem reasonable Equally interesting from a somewhat different standpoint is the rather curious dichotomy between hand-axe and non-hand-axe ("Clactonian") industries which has been documented for the Hoxnian interglacial itself This dichotomy — probably clearer in Britain than anywhere else in Europe — remains one of the most intriguing problems in Palaeolithic archaeology, for which a really convincing explanation still remains to be found

Evidence for the later stages of Lower and Middle Palaeolithic occupation is still infuriatingly vague Uncertainties of stratigraphic correlation, coupled with the lack of any reliable technique of absolute dating, renders any analysis of occupation during the Wolstonian and Ipswichian periods exceptionally difficult As Roe points out, there is a wide variety of industrial variants which must belong at some point within this time range, but in the absence of reliable dating any discussion of the meaning of this variation (chronological? cultural? functional?) must remain largely hypothetical and the question of interpretation open

One criticism that might perhaps be levelled at the book is that at some points it verges on the parochial, paying only limited attention to contemporaneous developments in other parts of Europe In the assessment of the earliest Palaeolithic industries this kind of comparison would certainly have been useful, and perhaps even more so in the discussion of the Middle Palaeolithic sites But this is at most a minor criticism and can hardly detract from the overall value of the book Dr Roe's major achievement is to have brought together a remarkably wide-ranging and diverse body of data, and to have presented it in a clear, well-integrated and easily accessible form By performing this task, he has produced what is clearly a classic of British prehistory that will serve as the definitive account of this period for many years to come □

Can even mere knowledge be a threat?

Academic freedom in the United States has come into conflict with national security. The Administration does not know what to do. The National Academy of Sciences should instruct it.

Stanford University has created an awkward problem for the National Academy of Sciences and, ultimately, for the State Department and the United States Administration Faced with an apparently routine communication from the academy relaying a new set of guidelines for restricting the access of overseas visitors to unpublished research, the university told the academy that the conditions were unacceptable They are that (see p 271) and unworkable as well The suggestion that overseas visitors should be kept in ignorance of unpublished research, for example, betrays ignorance of what university departments are like What else do these people talk about except what they are about to publish?

So, temporarily, the academy is embarrassed at having uncritically passed on a set of unpalatable instructions But it now has no choice but to decide where it stands on the question of national security and academic freedom, an increasing preoccupation of the Administration on which the academy's advice should long since have been sought The trouble is that there is nothing simple for the academy to say A ringing declaration of faith in academic freedom will not suffice, for there is more to the Administration's anxiety than mere xenophobia The academy must begin by teaching the Administration what American universities are for

Scholarship, while one of the chief custodians of tradition, is notoriously subversive of conventional wisdom, so that all scholars are potentially traitors to the establishment that supports them These simple truths, first learned at the Universities of Bologna and Paris, have been known for centuries They are now the basis of the accommodation which has been reached between universities and the rest of society in states confident enough of their political stability to indulge pretensions of liberality and civility Academics are licensed to teach and research as they choose, even when they are technically public servants (as in most European states) Governments, with varying degrees of reluctance, put up with the annoyance and inconvenience inevitably caused by the doctrine of academic freedom for two reasons — young people will otherwise be badly educated, while the new knowledge generated by scholarship is both enlightening and useful

The liberal accommodation between scholarship and society is, however, fragile In Poland in the past few weeks, the military government has evidently decided that academic freedom is more dangerous than benign the short-term benefits of compliance are judged to outweigh the long-term benefits of normality The Polish government's calculation may be accurate, if misguided The emergence of similar tendencies in the United States is not as easily explained

The analogy with Poland is merely superficial Nobody in the United States suggests that the government should decide which academics should teach what — and that unacceptable academics should lose their jobs Nor is it suggested that even students should pass tests of loyalty as well as examinations Indeed, the huffing and puffing there has so far been from agencies in Washington, the State Department and the Pentagon in particular, does not add up to a coherent policy, let alone a decisive break with the liberal habits of the past two decades Rather, it seems as if the Administration is going through one of its periodic attempts to make up its collective mind Senior officials make speeches, less exalted officials distribute circulars and members of Congress introduce bills that will never be debated.

The Administration's fears that free scholarship may be subversive of national security were put most clearly at the beginning of this year by Admiral "Bobby" Inman, now deputy-director of the Central Intelligence Agency but previously director of the National Security Agency (see *Nature* 14 January, p 88) The free publication of research may assist potential enemies, as may the traditional hospitality and liberality of American university departments But, the argument goes, the danger is not exclusively military The economic well-being of the United States may be as seriously damaged by the premature disclosure of commercially valuable high technology to a friendly but competing state So American universities, many of them among the engines of technical innovation, must be more circumspect Advance review of papers intended for publication may be necessary Restrictions on foreign visitors (some of which are permitted by existing legislation) may have to be made tighter And even general education may be suspect — Mr Frank Carlucci from the Pentagon was saying earlier this year (see *Nature* 7 January, p 3) that many visitors to American universities had gone on to posts in Soviet military establishments.

The Administration's case would be more convincing if there were not ample evidence that it is unsure of where it stands in its relationship with the outside world In its innocence — perhaps ignorance is the word — it habitually first sees the dark side of every international issue Yet all the fears that academic liberality may endanger the security of the United States are in reality double-sided questions Thus it is no surprise that foreign visitors to American universities benefit from their experience, or that they are afterwards promoted rapidly, the process by which they are selected would probably ensure that But indirectly, the American university system also benefits, as does scholarship as a whole This is why the Administration's decision to suspend the exchange agreement with the Soviet Union is a mistake

Admiral Inman's fears must be dealt with differently Again, however, it is true that the traditions of liberality benefit others than American taxpayers This is why there has been a running battle since the beginning of the Carter Administration about the prudence of open research on cryptography The ingenious development of the technique of what is called public-key cryptography was fully described in the open literature before the National Security Agency fully appreciated that an unbreakable code would benefit others than itself Much the same happened in 1938, but even more spectacularly, when Hahn and Strassman working in Germany published their first account of the neutron-induced fission of uranium The Admiral Inmans of this world must acknowledge that such accidents must happen repeatedly, and that they cannot be prevented without bringing academic research as such more or less to a halt They have three comforts In each case, the chances are high that similar discoveries would independently have been made elsewhere, while publication has ensured (at least where cryptography is concerned) that valuable commercial use can now be made of unbreakable codes The authorities must learn to live with this hard consequence of liberality, but may further comfort themselves with the knowledge that less liberal university systems have historically

0028-0836/82/040269-02$01 00

been less productive of good ideas and that on many occasions they can rely on the good sense of working scientists to anticipate trouble

There will be few complaints in the United States if the defence authorities now seek to build on this goodwill It would be entirely proper that they should remind people in laboratories that even seemingly academic developments may have defence implications Equally, it would be proper that university administrations should take a continuing interest in the problem It would, however, be a mistake for the military authorities to set up central machinery for supervising academic papers before publication Such a system could prevent the publication of sensitive material only by holding up a great deal of innocuous material Even then, it would make mistakes It would be far preferable that responsibility for deciding how the publication of potentially sensitive material should be arranged should rest with researchers and their universities The proposed arrangements for supervising research in cryptography, designed to shut the stable door after the bolted horse, should be abandoned

The general run of military research proper is more easily handled Since 1940, the Defense Department has learned to rely on American universities for a substantial part of its research and development Academics are well used to this kind of collaboration, and are apparently able without too much difficulty to marry their obligations to liberal teaching with their obligations of confidentiality to the Pentagon Whether the topic is formally registered as secret, or "classified", seems not to matter A more important consideration is that there are limits to the degree to which the university system can be laden with responsibilities for defence research without being compromised The irony is that, in the present economic climate, the universities are more willing collaborators and that the Pentagon seems glad of the welcome it now seems to enjoy from the universities

The issue of commercially important research is novel and fuzzier During the past decade, government agencies have been increasingly anxious that publicly supported research should have some practical relevance while, more cautiously, corporations have begun to recognize the potential of the academic research enterprise What seems not to have been appreciated is that many of those who help to carry through these unclassified programmes are nationals of countries other than the United States

But what is so strange about that? For even the most "relevant" of externally supported research programmes are not — and should not be — programmes of development Most of them are projects intended to gather basic information in some obvious field The fear that foreign visitors may carry off unique information in fields such as the molecular biology of genetic engineering or the development of techniques for making Very Large Integrated circuits is predicated on the assumption that nobody else knows about these important industrial goals That conceit is almost always an illusion It should not be allowed to compromise the civility and freedom of academic research In any case, the agencies and the corporations have the remedy in their own hands They decide what research contracts should be let

Why arms control?

Will arms control fall foul of too literal an interpretation of Kissinger détente?

This has been a bad week for arms control Mr Alexander Haig's long-arranged meeting with Mr Andrei Gromyko in Geneva was being advertised in advance, in Washington at least, as a discussion exclusively about recent events in Poland The promised resumption of bilateral negotiations on strategic arms are apparently to be postponed indefinitely At the same time, there have been mutterings in Washington that the talks now under way in Geneva on the control of weapons in Central Europe may be reduced to one session a week unless there is some sign of let-up in martial law from Warsaw Both developments are consistent with the case argued forcefully last week by Dr Henry Kissinger, previously United States Secretary of State and the architect both of the concept of *détente* and of several arms control agreements between the Soviet Union and the United States In two pungent articles, Dr Kissinger restated his familiar argument that peace is indivisible, and that a succession of agreements on arms control is in itself insufficient, even insubstantial The present Administration has obviously been angered by much of what he said Its responses this week suggest that it is nevertheless prepared to listen

Can this be wise? The Kissinger doctrine of "linkage" is politically and tactically impeccable In making an accommodation with an adversary, and on the assumption that neither side will abandon what it considers to be its essential interests overnight, it is prudent to seek agreements which provide each side with incentives to toe the line and deterrents (not necessarily nuclear) against backsliding The essence of the Kissinger–Nixon theory of *détente* is that the United States would offer the carrot of high technology and trade, gaining in return the relatively insubstantial benefits of the Helsinki agreements and of *détente* itself The corresponding deterrents were ultimately supposed to be what they have been ever since 1946 One essential element in Dr Kissinger's argument, not restated but substantially unchanged, is that it should be possible to withdraw the carrots quickly, making the sticks loom larger Dr Kissinger last week was scornful of the growing United States dependence on the international trade with the Soviet Union in foodstuffs His articles appeared before France had followed West Germany in agreeing to buy substantial quantities of natural gas from the Soviet Union but his arguments do not apply, as seems to be supposed, to the process of negotiating, as distinct from ratifying, agreements on arms control

That conclusion can be reached without much difficulty The experience of the past few years has shown that the parties most acutely embarrassed in negotiations are those who feel bound to reject sensible proposals The United States Administration has turned up at Geneva with an in-built advantage — President Reagan's declaration in November that he (but not necessarily Congress) would settle for the "zero option" — no nuclear missiles (as distinct from aircraft) of any kind in Europe The general opinion, borne out by such official Soviet statements as there have since been, is that Mr Reagan was offering a clever bargain, as much a stick as a carrot Does it make sense, having raised such a possibility, to allow the discussion of this proposal to slip into the background noise, like the continuing negotiations in Vienna on the reduction of conventional forces in Europe? For that matter, can it make sense, if the United States seriously believes it has a moral advantage because of Poland, that Mr Haig should so ostentatiously fail to raise with Mr Gromyko the matter of how far the Soviet Union might be prepared to go on a replacement treaty for Salt II?

The underlying difficulty is that, on arms control, while the more important negotiations are bilateral between the United States and the Soviet Union, neither party is as free as it supposes Paradoxically, the negotiators must constantly have in mind the electorates of countries other than their own Or they should The willingness of the government of France to contract for a decade's supply of natural gas from the Soviet Union should be a reminder that France is a European state The nervousness of the Bonn government about the future of Central Europe is also a measure of the more general concern that alternative governments would pose more complicated problems And who supposes that all members of the Soviet government have slept soundly at nights during the past momentous eighteen months? Mr Haig should talk, not sulk

The moral is, or should be, simple Talking about arms control is better than sulking Talking about arms control to a potential partner at a moral disadvantage may be especially productive Not to talk at all, or to talk only one day a week, is silly And is there not always a chance that the process will itself be worthwhile? In short, the United States should feel free to speak up at Geneva and elsewhere without fear of selling itself short — or of offending Dr Kissinger

Academic freedom and security conflict

Challenge to access rule from Stanford

Washington

The National Academy of Sciences (NAS) moved quickly last week to disengage itself from efforts by the US State Department to restrict ideas that American university research workers are allowed to discuss with visiting Soviet scientists

The academy was responding to complaints that, in administering the exchange programme between scientists from the two countries, NAS officials have been routinely passing on instructions from the State Department about limitations to be placed on particular individuals

Scientists at Stanford University in California objected earlier this month to the academy when such a letter was received covering the proposed visit of Dr Nikolay V Umnov, an expert in robotics and walking machines, to the university's department of mechanical engineering It was to be one of a series of visits which the Soviet scientist had requested to universities throughout the country

NAS officials told the university that Dr Umnov's visit had been approved by the State Department, but only under certain conditions He was not to be allowed access to data about programming techniques for robots, nor was he to make any industrial visits to companies with Defense Department contracts The State Department has said that, unless waivers were negotiated with the Department of Defense, Dr Umnov was not to be allowed access to unpublished results of Department of Defense sponsored research even if this was unclassified The academy passed these instructions on to the five universities Dr Umnov was to visit

Following a complaint from Dr Bernard Roth, a professor in the department of engineering the university's dean of research, Dr Gerald J Lieberman, wrote back saying that Stanford was prepared to sponsor Dr Umnov's visit, but refused to accept the conditions imposed by the State Department

"We are not willing to accept responsibility for Dr Umnov's actions — either on or off the campus — during his visit to Stanford," Dr Lieberman wrote He added that the NAS memorandum was a surprise, saying that "we believe that the best interests of American science and technology are served by open exchanges of university research activities and hope that the academy will visibly support universities' position on this critical issue"

A spokesman for the academy said last week that it had been decided to suspend the simple transmission of restrictions required by the State Department until the governing board of the National Research Council and the council of the academy "has had a chance to examine the whole thing from the policy point of view" Both bodies meet next month

As efforts have been made to tighten restrictions on visiting scientists, concern about the implications have been growing on US campuses A year ago, Stanford sent a letter on behalf of the presidents of five major research universities to the Department of Defense, Commerce and State, complaining that such a tightening could seriously hamper the work of the scientific community The president of the academy, Dr Frank Press, has also expressed publicly his concern about suggestions from the deputy director of the Central Intelligence Agency, about the need for greater caution in the publication of research results in fields such as lasers and computer software

Last year a group set up jointly by the National Security Agency and the American Council on Education agreed to establish a system by which research results in cryptography could be voluntarily submitted to a review committee before publication, to determine whether the data should be withheld on national security grounds The academy has to agree to accept a request that it nominate two members of the review committee, a move which could be taken as endorsing the idea

Harvard guidelines for avoiding fraud

Washington

A national conference involving both the National Institutes of Health (NIH) and the nation's research universities should be convened to consider a number of "unanswered questions" about dealing with suspicions of falsified research data, according to a committee of inquiry set up by Harvard Medical School to investigate the circumstances surrounding the admitted fabrication of data by a scientist studying the prevention of heart attacks (see *Nature* 24/31 December 1981, p 584)

The committee, chaired by Dr Richard S Ross, dean of Johns Hopkins Medical School, has given its general approval of steps taken by the medical school after colleagues discovered that Dr John R Darsee was faking some of the raw data in an experiment in May 1981

In its report, which was published in Boston on Monday, the committee describes how Dr Darsee was stripped of his position as a research fellow, as well as being removed from staff positions at the Brigham and Women's Hospital, as soon as the fabrication of data had been confirmed, and that his NIH research fellowship was removed at the same time The medical school denied on Monday that it had been wrong to keep Dr Darsee involved in research at another laboratory in Harvard, or that it had been slow to raise public warning signals about his research, claiming that it had been some time before an internal investigation revealed just how extensive the fabrication of data may have been, and that up to that point Dr Darsee had gained a reputation as a talented and hard-working research worker

The report of the review committee, which was set up at the invitation of the dean of Harvard Medical School, Dr Daniel Tosteson, says that it considers the medical school's response to have been appropriate for what was known at the time

The committee makes two specific recommendations to the medical school First, it should establish a committee of senior faculty members that can be called upon to investigate any suspicion of fraudulent data gathering And second, the medical school should improve the internal communication system, so that people can be informed confidentially if a research worker under suspicion in another department has any connection with their own research In the case of Dr Darsee, colleagues in the laboratory in which he was allowed to continue working were not aware of the charges made against him elsewhere in the medical school

The committee also makes some general suggestions about how the scientific community might take steps to make it harder for an individual to publish false results For example, it criticizes the practice of publishing small batches of research findings in a number of different publications, rather than concentrating them in a single, major publication, more likely to receive close scrutiny from the scientific community

The committee also suggests that laboratories should agree on explicit procedures for data gathering, storage and analysis, and that these should be written up and be generally available to research workers In Dr Darsee's case, he was unable to produce much of the raw data on which some of his research results were based, although the committee found that it was general practice in the laboratory that such data should be preserved

Finally, the review committee suggests a national conference to look at the whole area of the falsification of research Topics which it says a conference might address would include what the responsibility of an institution discovering dishonesty among its research staff should be with respect to other institutions, the scientific and medical community and the general public

of pre-publication review in selected areas of research

Despite several meetings with government agencies held over the past year, university officials report little indication that the government is prepared to relax its restrictions, in view of the prevailing political climate in Washington

Last Friday, the State Department said that Stanford University would not be included in Dr Umnov's visit since it had refused to recognize the department's restrictions on what he should be allowed to do Scientists at the University of Wisconsin also said they were withdrawing their offer to host a visit from Dr Umnov in the light of the department's actions

The Soviet scientist's trip will still include one week at Aubrun University in Alabama, and "two or three days" at Ohio State University Professor Robert McGhee of Ohio State has said that, although Dr Umnov was originally to spend six weeks at the university, he was only prepared to accept the State Department restrictions for the shorter length of time **David Dickson**
